Medical Historian Retires from Johns Hopkins.—Dr. John Rathbone Oliver, since 1930 associate in the history of medicine at Johns Hopkins University School of Medicine, Baltimore, having reached 67 years of age, is retiring. Dr. Oliver received his medical degree at the University of Innsbruck, Austria, in 1910, and the degree of doctor of philosophy from Johns Hopkins in 1927. He was a surgeon in the Austrian Army, 1914-1915; psychiatrist at Johns Hopkins Hospital, 1915-1917; chief medical officer to the Supreme Bench of Baltimore, 1917-1930, and professor of the history of medicine at the University of Maryland from 1927 to 1930.

MICHIGAN

University Promotions.—Dr. David A. Boyd Jr., Ann Arbor, has been promoted to be assistant professor of psychiatry at the University of Michigan Medical School and Russell T. Woodburne, Ph.D., to be assistant professor of anatomy.

First Mental Hygiene Institute.—The Michigan Society for Mental Hygiene, the Kalamazoo Mental Hygiene Committee, Western State Teachers and Kalamazoo colleges cooperated in holding the first statewide mental hygiene institute in Kalamazoo July 17-21. The speakers included Maud E. Watson, Ph.D., director, Children's Center, Children's Fund of Michigan, Detroit; Dr. David Slight, professor of psychiatry, University of Chicago; Dr. William H. Kelly, Lansing; Dr. Harry E. August, Detroit, and Fritz Redl, Ph.D., University of Michigan, Ann Arbor.

Changes in Health Officers.—Dr. Merle R. French, commissioner of health of Cortland and Cortland County, N. Y., has been appointed director of the Van Buren County Health Department with headquarters in Paw Paw.—Dr. Kalman S. Von Haitinger, formerly of the Hillsdale County health department, has been appointed health officer of the Midland County health department succeeding Dr. Edwin H. Place, resigned.—Dr. Erwin F. Hoffman, Mason, has been appointed director of the Dickinson County health unit to succeed Dr. Philip E. M. Bourland, Iron Mountain, resigned.

Personal.—Dr. Floyd J. Barkman has resigned as head of the Berrien County Hospital, Berrien Center, a position he has held since the hospital was opened May 5, 1937, it is reported. The resignation was effective August 1.—Dr. William T. King, Ahmeek, head of the medical staff of the local mine for the past thirty-five years, was honored by more than 400 employees of the mine when he was presented with a gold watch and a clock and fountain pen, and a leatherbound book containing all the signatures of the employees.—Dr. Marie A. Hagele, Chicago, has been appointed regional consultant in maternal and child health for the state department of health, effective June 1. Dr. Emily L. Ripka, who has been doing postgraduate work at Harvard University, has returned to the department as a regional consultant.

Advisory Council of Health Reorganized.—The appointment of new members to the state advisory council of health, serving in an advisory capacity to the state health commissioner, has been announced. New members include Drs. Carleton Dean, Charlevoix, director of district health department number 3; Addison D. Aldrich, Houghton; Roy C. Perkins, Bay City; John L. Lavan, health officer of Grand Rapids, and Henry F. Vaughan, Dr. P.H., health officer of Detroit. Retiring members of the council include Drs. Robert B. Harkness, Hastings; George J. Curry, Flint; William Lloyd Kemp, Birmingham; H. Lee Simpson, Detroit, and P. C. Lowery, D.D.S., Detroit. Dr. Vaughan was elected president and Dr. Lavan secretary. At the first meeting of the reorganized council May 26, it approved the regulation that hereafter all medical examination certificates issued by physicians outside of Michigan must be forwarded by the county clerk to the Michigan Department of Health for approval before such certificates may be accepted.

MISSOURI

Personal.—Dr. Evarts Graham, Bixby professor of surgery, Washington University School of Medicine, St. Louis, has served this year as head of the summer teaching surgical unit at St. Bartholomew's Hospital, London. The *Medical Alumni Quarterly* of the university said that Dr. Graham is the first American surgeon to be invited for this position, which is offered in alternate years to distinguished British surgeons.

Annual Clinical Conference in Kansas City.—The seventeenth annual fall clinical conference of the Kansas City Southwest Clinical Society has been set for October 2-5. The guest speakers, many of whom will speak several times, will be:

Dr. William Edward Chamberlain, Philadelphia, roentgenology.
Dr. George M. Curtis, Columbus, Ohio, surgery.
Dr. Temple S. Fay, Philadelphia, neurology.
Dr. Russell L. Haden, Cleveland, internal medicine.
Dr. Robert I. Harris, Toronto, Ont., orthopedic surgery.
Dr. Chevalier L. Jackson, Philadelphia, otorhinolaryngology.
Dr. Elliott P. Joslin, Boston, internal medicine.
Dr. Frank H. Lahey, Boston, surgery.
Dr. William H. Luedde, St. Louis, ophthalmology.
Dr. John L. McKelvey, Minneapolis, obstetrics and gynecology.
Dr. Albert Graeme Mitchell, Cincinnati, pediatrics.
Dr. Max M. Peet, Ann Arbor, Mich., surgery.
Dr. Curtice Rosser, Dallas, Texas, proctology.
Dr. James P. Simonds, Chicago, pathology.
Dr. Rock Sleyster, Wauwatosa, Wis., President of the American Medical Association, psychiatry.
Dr. Howard B. Sprague, Boston, internal medicine.
Dr. Gilbert J. Thomas, Minneapolis, urology.

There will be three round table conferences on diseases of the chest, treatment of common anorectal conditions and toxemias of pregnancy. There will also be round table luncheons and each day. The Kansas City Society of Ophthalmology and Otolaryngology will sponsor a program Thursday October 5 with Dr. Luedde and Dr. Jackson as the guests. There will be scientific and technical exhibits and a hobby show.

NEBRASKA

Annual Registration Due on or Before October 1.—Physicians licensed to practice medicine in Nebraska are required by law to register with the Department of Public Welfare annually, on or before October 1, and to pay a fee of \$1. A license expires if the licensee fails to register, but within the thirty days next following its expiration it may be

revived by the payment of the registration fee and a penalty of \$1. If that is not done, an order of revocation is issued and thereafter the revoked license can be reinstated only on the recommendation of the board of examiners in medicine and on the payment of the renewal fees and penalty then due.

NEVADA

State Medical Meeting.—The annual meeting of the Nevada State Medical Association will be held in Reno September 22-23. The following speakers appear in the program: Dr. Laurence R. Taussig, San Francisco, Cutaneous Epitheliomas; Dr. Fletcher B. Taylor, Oakland, Calif., Medical Follicles of 1938; Dr. Edward B. Shaw, San Francisco, Principles of Treatment of the Common Contagious Diseases; Dr. Roger Anderson, Seattle, Fractures in the Region of the Hip; Dr. Rupert B. Raney, Los Angeles, Temporal Lobe and Cerebellar Tumors and Sympathectomy in Angina Pectoris; Dr. Everett B. Muir, Salt Lake City, Treatment of Small Injuries of the Eye; Dr. Robert C. Martin, San Francisco, Ear, Nose and Throat in General Practice; Dr. Ralph T. Richards, Salt Lake City, Oxygen Therapy; Dr. Paul G. Flothow, Seattle, Treatment of Vascular Lesions of the Extremities; Dr. Eugene S. Kilgore, San Francisco, Syphilis of the Central Circulatory System.

NEW YORK

Poliomyelitis in Buffalo.—Sixty-four cases of poliomyelitis in Buffalo between July 27 and August 29 led the health department to order public swimming pools closed, the New York Times reported August 30. Theaters were requested to refuse admission to children until further notice.

Urologic Meeting.—The Western New York and Ontario Branch of the American Urological Association will hold its ninth annual meeting in Buffalo September 15-16. The first day's session will be at the New York State Institute for the Study of Malignant Disease. Dr. Burton T. Simpson, director of the institute, will demonstrate methods of preparing radium for urologic cases and of high power therapy. There will be round table discussions and a special scientific exhibit. The Saturday program at the Hotel Statler will include addresses by Dr. William S. McCann, Rochester, on "Newer Developments in Hypertension"; James B. Hamilton, Ph.D., New Haven, Conn., "Male Hormones," and Dr. Ross H. Flett, Toronto, "Multiple Primary Malignancy in the Urinary Tract."

New York City

Symposium on Silicosis.—The Tuberculosis Sanatorium Conference of Metropolitan New York will sponsor a symposium on silicosis at the Cornell University Medical College amphitheater, October 11. Dr. Grant Thorburn will preside and the speakers will be Drs. Anthony J. Lanza on the etiology and diagnosis; John R. Carty, the radiographic aspect, and Mr. Theodore C. Waters, Baltimore, the medicolegal aspect.

Courses for Graduates.—Two courses of eight weeks each, reviewing recent advances in clinical medicine and important technical procedures, will be offered by Columbia University to qualified graduates in medicine during the winter. One is announced for the period between November 6 and December 30 and the other from February 5 to March 30. Both will be given at Mount Sinai Hospital. Information may be obtained from the dean of the school of medicine, Columbia University, 630 West One Hundred and Sixty-Eighth Street, New York.

NORTH CAROLINA

Convalescent Home for Crippled Children.—The Asheville Orthopedic Home, sponsored by the Rotary Club of Asheville and the Asheville Junior League, was dedicated July 30. Funds for the new headquarters were collected in a drive last winter. Establishment of the home, which is equipped to care for forty convalescent orthopedic patients, is an outgrowth of the Asheville Crippled Children's Clinic started twelve years ago by Dr. Edward King, now of New York. The clinic was at first held once a month, but for the past three years clinics a month have been held in Asheville and one in Bryson City. All clinics are now held in Asheville. Operations are performed in Asheville hospitals and the children are then removed to the home for convalescent care. All patients are admitted through the clinic. In addition to the local support, the state division for crippled children will finance the care of some children with state and federal funds. Dr. John T. Saunders, Asheville, who has conducted the clinic for the past six years, is the orthopedic surgeon in charge of the past year. At the dedication July 30 Drs. Carl V. Reynolds, state health officer, formerly of Asheville, and Joseph Warren White, orthopedic surgeon in charge of the Shriners Hospital for Crippled Children, Greenville, S. C., were the principal speakers.

OKLAHOMA

Faculty Changes at Oklahoma University.—The following promotions, among others, were recently announced by Dr. Robert U. Patterson, dean, University of Oklahoma School of Medicine, Oklahoma City: Dr. Henry H. Turner, to be associate professor of medicine; Dr. Ernest Lachmann, associate professor of anatomy; Dr. Leo F. Cailey, Edmund Gordon Ferguson, James Jackson Caviness, James Robert Reed and Fay Maxey Cooper, assistant professors of ophthalmology.

Among new appointments announced were the following: Irwin Clinton Winter, Ph.D., to be assistant professor of pharmacology; Harold A. Shoemaker, Ph.D., professor of pharmacology, appointed vice dean, succeeding Louis A. Turley, Ph.D.; Dr. Owen Royce Jr., assistant director, outpatient department of the University and Crippled Children's hospitals; Dr. Maynard S. Hart, assistant director of the laboratories at the University and Crippled Children's hospitals.

OREGON

Society Suggests Curb on Ambulance Speeding.—The council of the Oregon State Medical Society at a recent meeting adopted a resolution urging that emergency vehicles such as ambulances be operated in accordance with state laws and local traffic ordinances. The council stated that it did not favor promiscuous speeding by ambulances and is of the opinion that under most circumstances it is in the best interests of the patient and the public for ambulances to be operated at normal rates of speed and without the extensive use of sirens or horns. The resolution was sent to all component societies with the request that each society try to obtain adoption of this policy in its community.

PENNSYLVANIA

Society News.—A discussion of sulfanilamide and sulphydryl featured the meeting of the Lycoming County Medical Society, Williamsport, July 14; the speakers were Drs. James Stanley Smith on infections of the genito-urinary tract; Alexander W. Blumberg, sulfapyridine in the treatment of pneumonia, and Carl J. Baier, Williamsport, infections of the upper respiratory tract.

Philadelphia

Promotions and Appointments at Jefferson.—The following promotions and appointments in the teaching corps of the Jefferson Medical College were made during the last session: Dr. Bernard J. Alpers, professor of neurology; Dr. Lewis C. Scheffey, clinical professor of gynecology; Dr. Arthur J. Davidson, clinical professor of orthopedic surgery; Dr. Edward F. Corson, clinical professor of dermatology; Dr. Creighton H. Turner, associate professor of medicine; Dr. Garfield H. Duncan, associate professor of medicine; Dr. Abraham Cantarow, assistant professor of medicine; Dr. Robert A. Matthews, assistant professor of psychiatry; Dr. Leandro M. Tocantins, assistant professor of medicine.

SOUTH DAKOTA

Basic Science Board Appointed.—Pursuant to a law passed by the 1939 legislature, Governor Bushfield has appointed a basic science board. The members are Dr. James D. Alway, Aberdeen; F. E. Burkholder, D.O., Sioux Falls; M. L. Severance, Aberdeen, chiropractor; William H. Waller, Ph.D., professor of anatomy, University of South Dakota School of Medicine, Vermillion, and Gregg M. Evans, Ph.D., professor of chemistry and physics, Yankton College, Yankton.

TEXAS

Personal.—Dr. Van C. Tipton has been appointed director of the health department of the city of San Antonio.—Dr. and Mrs. John Mark O'Farrell, Houston, celebrated their fiftieth wedding anniversary August 14.—Dr. Ernest W. Prothro, Corpus Christi, has recently succeeded Dr. Thomas B. Wilson as health officer of Nueces County and Corpus Christi.

Society News.—Dr. Cullen H. Hendry, Beaumont, addressed the Jasper-Newton Counties Medical Society, Kirbyville, recently on nasal allergy.—At a meeting of the Wichita County Medical Society in Wichita Falls recently in conjunction with the Northwest Texas Health Association the speakers were Drs. Elbert W. Wright, Bowie, on "Relationship of Public Health to Organized Medicine"; David L. Robertson, Wichita Falls, "Functions of a Venereal Clinic," and Robert B. Wolford, Mineral Wells, who showed a motion picture on syphilis.—The Dallas Academy of Internal Medicine was recently organized with these officers: Drs. David W. Carter Jr., president; Walter G. Reddick, vice president, and Edward S. Ross, secretary.—Dr. Cleve C. Nash, Dallas, addressed the Cooke County Medical Society, Gainesville, July 10, on diagnosis and treatment of head injuries.

WISCONSIN

Examination for Psychiatrist.—The Milwaukee County Civil Service Commission will hold examinations for medical director of the county asylum and hospital for mental disease in the near future. Applications must be filed by September 22 with the commission, room 206, Court House, Milwaukee. The salary is from \$4,500 to \$5,000 with full maintenance for the physician and family. The examination will be open to graduates of medical schools licensed or eligible for license in Wisconsin, with one year's postgraduate training in neuropsychiatry or the equivalent, five years' institutional experience, ability to direct, organize and coordinate staff and employee activities, good health, personality and professional ability.

PUERTO RICO

League Against Cancer.—The Puerto Rican League Against Cancer has carried on a campaign since its organization in 1938, a recent report indicates. The league cooperates in the establishment of clinics and dispensaries, provides aid to curable indigent patients, and encourages clinical and experimental study of causes and treatment. An educational campaign also has been carried forward. The legislature enacted a law creating a cancer institute and allotting \$200,000 for a building and equipment, but an appropriation is lacking at present to carry this plan into effect. Funds raised during the last year enabled the league to buy x-ray equipment and the president, Dr. Isaac F. Gonzalez-Martinez, San Juan, donated 50 mg. of radium for a free emergency clinic. Hospitalization has been provided for a number of patients. It is expected that the National Cancer Institute of the U. S. Public Health Service will grant a loan of 200 mg. of radium. Local committees of the league have reported that there are candidates for hospitalization and treatment in all of the fifty-five towns represented.

GENERAL

International Hospital Congress Canceled.—Dr. Malcolm T. MacEachern, Chicago, president of the International Hospital Congress which was to have been held in Toronto September 19-23, announced September 2 that the congress has been canceled because of the European war.

Bibliography on Nutrition.—The community education section of the American Dietetic Association has recently published a bibliography on normal nutrition. It lists twelve reference and text books on nutrition, ten "more readable—less technical books," and seven recent review articles. The bibliography is available at the offices of the association, 185 North Wabash Avenue, Chicago, for 10 cents a copy.

Paper Industry Sponsors Bacteriologic Research.—The paper industry, through the American Paper and Pulp Association, has launched a program of bacteriologic research which it is believed will contribute to better understanding of sanitary problems involved in manufacture and conversion of paper to be used in packaging foods. The Institute of Paper Chemistry, Appleton, Wis., will carry on the fundamental work prerequisite to the establishment of standard technics and Fred W. Tanner, Ph.D., Urbana, Ill., will work with the institute in an advisory capacity.

Prize in Thoracic Surgery.—The American Association for Thoracic Surgery announces a prize of \$250 to be awarded at the next annual meeting for the best paper submitted to the program committee on some subject relating to the study of chest diseases. The prize is offered by the Rose Lampert Graff Foundation of Los Angeles. Any physician in good standing in the United States or Canada may submit a paper to the committee, of which Dr. Richard H. Meade Jr., 2116 Pine Street, Philadelphia, is secretary, before March 1, 1940. The committee will award the prize only if in its opinion a paper of sufficient merit has been presented. If the prize is not awarded in 1940 it will be held over for 1941. The 1940 meeting will be in Cleveland June 6-8.

Surplus Food to Be Used for School Lunches.—The U. S. Department of Agriculture announced August 22 that a program of providing free lunches for undernourished school children carried out last year in 14,000 schools would be expanded during the coming term to serve five million children. The school lunch program is carried out by the Federal Surplus Commodities Corporation in cooperation with the Works Progress Administration and local educational, civic and welfare agencies. Surplus agricultural products are bought by the FSCC and made available to schools through state welfare agencies. Last year 800,000 children in every state as well as in Puerto Rico and the Virgin Islands participated in the free lunch program, utilizing more than thirty million pounds of fifty-four different food commodities.

Public Health Meeting in Pittsburgh.—The sixty-eighth annual meeting of the American Public Health Association will be held in Pittsburgh October 17-20, with the sixth annual institute of public health education as a preliminary feature. Headquarters will be at the Hotel William Penn. Six general sessions are announced. Dr. Edward S. Godfrey Jr., Albany, N. Y., will give his presidential address and Dr. Milton J. Rosenau, Chapel Hill, N. C., will inaugurate the Delta Omega lectureship with a lecture entitled "New Lamps for Old." At other general sessions subjects of discussion will be: medical care, the "American way" as seen from abroad, cancer and professional education. Symposiums announced for sections, singly and in joint sessions, include: illness in industry and its control, pneumonia, food poisoning, gastro-enteritis, nutrition, venereal diseases and the newer venereal diseases. The institute of health education will be held October 15-17.

Mississippi Valley Tuberculosis Meeting.—The twenty-sixth annual meeting of the Mississippi Valley Tuberculosis Conference and the Mississippi Valley Sanatorium Association will be held at the Hotel Fontenelle, Omaha, September 20-22. The first day the tuberculosis conference will hold a child health program and Thursday the two groups will hold a joint meeting. Among speakers who will appear are:

Dr. Calvin C. Applewhite, U. S. Public Health Service, Chicago, Tuberculosis Control Aided by Effective Vital Statistics.
Drs. Arthur A. Pleyte and Edward K. Steinkopf, Milwaukee, Screening for Tuberculosis by Fluoroscopy.
Dr. Kenneth L. Burt, Howell, Mich., Pulmonary Tuberculosis and Moniliasis: A Study of 500 Patients.
Dr. Sumner S. Cohen, Oak Terrace, Minn., Review of Tracheobronchial Tuberculosis.

Dr. Henry D. Chadwick, Waltham, Mass., president of the National Tuberculosis Association, will speak at the annual banquet Thursday evening. Dr. Hyman I. Spector, St. Louis, is president of the tuberculosis conference and Dr. William J. Bryan, Rockford, Ill., of the sanatorium association.

Report on the Study of Suicide.—The Committee for the Study of Suicide, Inc., established in January 1936, has recently made a report of the progress of its work. The committee has made studies at Bellevue Hospital, New York; the Psychopathic Hospital of the University of Denver; McLean Hospital, Belmont, Mass., and the Institute of Psychoanalysis, Chicago. At Bellevue 1,227 patients have been examined and eighty-one of them in much detail. In 1936 6 per cent of the total admissions to the hospital were for attempted suicide, and in 1937 the percentage was 5.7. More than half of these patients were between 22 and 40 years old. In Denver 134 patients were studied, of whom fifty-one had suicidal trends. At McLean Hospital forty-four cases of suicide were studied and seventy-five patients with suicidal trends. At the Institute of Psychoanalysis in Chicago three analyses have been completed and four patients are still under analysis. The committee plans to publish several volumes as soon as the records of its various projects have been collected. The committee's headquarters are at 57 West Fifty-Seventh Street, New York, and the secretary and director of research is Dr. Gregory Zilboorg.

CANADA

Quebec Hospital Celebrates Tercentenary.—The Hotel-Dieu de Quebec celebrated its three hundredth anniversary August 23-28 during the biennial convention of the hospitals of Quebec. The *Canadian Medical Association Journal* says that this is the oldest hospital in Canada and, with the possible exception of one in Mexico, the oldest in North America. The hospital was founded by three nursing sisters of the Order of Augustinians of Dieppe, France, who came to Canada at the expense of the Duchesse d'Aiguillon, a niece of Cardinal Richelieu, after colonists had appealed for aid. The hospital was conducted in various buildings through the years and in 1755 the building was burned with nearly all the old records and equipment. At present it is a modern hospital with 350 beds and is a teaching unit of Laval University. It is said that the Hotel-Dieu de Quebec developed the first outpatient department in the country and that it was the first hospital to train nurse attendants.

CORRECTION

Neurology and Neurosurgery.—In the Educational Number of THE JOURNAL August 26, page 846, in conformity with an official report from the University of Chicago Clinics, there was listed an approved residency in neurology. A later report from the university indicates that this service includes also neurosurgery.

Mobilization of Physicians for War

Government plans for the mobilization of physicians in war have been announced by the Ministry of Health. They have been agreed on between the ministry and the Central Emergency Committee of the British Medical Association. The scheme provides for a national hospital medical service for the treatment of casualties. Physicians joining it will assume for a period of three years a definite liability to serve in an emergency. The service will be recruited from physicians other than those already in whole-time employment of the government or the local authorities. There will be two classes of service: Class A physicians will in an emergency be called up for whole-time hospital service with liability to transference to any part of the country. Those required at the outset will be called up as soon as an emergency arises; others will be called up later as required. Class B physicians will be liable to hospital service on a sessional basis in their own hospital area. The scale of salaries in class A areas follows: consultant adviser \$7,000, group officer \$6,500, medical superintendent of a hospital of 1,000 beds and over \$6,000, of 750 beds \$5,000, of 300 beds \$4,500, officer in charge of surgical or medical division hospital of 500 beds and over \$4,750, specialists \$4,000, medical officers \$2,750, house officers \$1,750. The salaries are on a resident basis; if board and lodging are not supplied, an allowance of \$500 will be paid in lieu thereof. Class B physicians will be paid \$13 a session for consultant and specialist work of two hours' duration up to five sessions in any one week with \$10 for other sessions. General practitioners will be paid \$8 a session of two hours' duration. Physicians so employed will not wear a uniform but a distinguishing badge. They will be allocated to their wartime positions now. Thus there will be created in peace time an expanded system of casualty hospital staffs which can function automatically at a moment's notice. This will involve allocation to hospital staffs of physicians engaged in private practice, but the British Medical Association has elaborated a scheme for the maintenance in every area of an adequate number of physicians and the safeguarding of the practices of those who are called up.

An Orthopedic Unit for China

During the past year the Chinese Red Cross has come to realize the importance of orthopedics in war surgery and has sent an appeal to the British Orthopedic Association, which was asked to provide a small teaching unit (250 beds) to be established behind the Chinese lines, and a surgical director to instruct Chinese surgeons in orthopedics so that they will be able to deal more competently with the enormous numbers of wounded in their hospitals. A sum of \$1,750 is required, \$50 for each bed and \$5,000 for special equipment. It is most unusual for a small and purely scientific body such as the British Orthopedic Association to undertake a responsibility of this kind, but it felt that the appeal could not be refused. Its members (all the British orthopedic surgeons) have given more than \$5,500 in sums varying from \$5 to \$500. As they cannot subscribe all that is required, they have asked, in cooperation with the British Fund for the Relief of Distress in China, the aid of the medical profession as a whole. In the appeal issued over the signature of the president, Mr. Naughton Dunn, it is stated that this country has given the world Sir Robert Jones, the greatest orthopedic surgeon of all time, and it is natural that another country desperately in need

of enlightenment in the treatment of limb and spinal injuries should look to us. With necessary support it will be possible to dispatch a surgeon with little delay, as arrangements for administration of the fund have just been completed. He will instruct the Chinese surgeons in orthopedic surgery.

The Fight Against the Tsetse Fly

The tsetse fly, carrier of the trypanosome of two fatal diseases—trypanosomiasis in man and nagana in cattle—dominates about one fourth of the continent of Africa, where it is holding up colonial development. First discovered in Uganda in 1901, trypanosomiasis had it was estimated killed in the whole of the affected area more than 200,000 out of a population of 300,000. Only the unceasing efforts of a band of workers eventually stemmed the tide and saved other tribes from extinction. Whole tracts of the shores of Victoria Nyanza had to be abandoned, and their resettlement has been possible only in the last four years and then under the strictest control. The story of Uganda could be repeated in fifty other districts. In huge areas of the Congo, 80 per cent of the inhabitants are suffering from trypanosomiasis.

Of the drugs produced for the treatment of trypanosomiasis three—atoxyl, antrypol and tryparsamide—are in common use. The first two will cure early cases but fail in advanced ones. Tryparsamide is more efficacious, but if the initial treatment does not eliminate the disease the trypanosomes become arsenic fast and, what is more serious, persons subsequently infected by one of these strains cannot be cured by arsenic. Obviously the only solution would be eradication of the fly, but this is impossible in a vast continent with the tsetse fly's main stronghold in the undeveloped wilds. What is being done is to concentrate on the places where the fly and man are in close contact. The physiology and ecology of the tsetse fly and every aspect of its infection by trypanosomes have been minutely studied. It has been proved that it hunts by sight and not by smell. An effective pupa trap costing a few cents has been devised. Bush clearing, by destroying the primary haunt of the fly, has proved successful. With riverine species this is not difficult, and it has been shown that it is not necessary to cut out the whole riverine vegetation. Blocks can be left in which the fly can be exterminated by hand catching. But clearing would involve hundreds of square miles and the cost would be prohibitive. The method adopted is to cut long corridors and deal by various methods with the isolated blocks. Control of grass burning, an annual custom among the pastoral and hunting tribes, has proved effective. Fiercer fires destroy the breeding places. Game reduction has been successful in Rhodesia, but this drastic measure has, apart from other considerations, two dangers. Such a radical change in a country's fauna must have far reaching effects. If, as has happened in some cases, the game is exterminated, the fly may concentrate on man and domestic stock. In spite of these efforts and local successes, the fly is spreading into new districts. This is largely due to the opening up of the country and improvements in transportation.

Hospital Provident Scheme for the Middle Classes

Provident schemes for the working class by which small weekly payments entitle the members to hospital treatment if they should require it have been established in recent years. Schemes for the middle classes have been under discussion for some time. Definite proposals have at last been made and were mentioned by the duke of Kent at the council meeting of King Edward's Hospital Fund. The scheme is designed to afford to subscribers complete coverage for a period up to four weeks in a pay bed of a hospital and will be based on agreement by the hospitals and the specialists and consultants

to accept suggested rates of fees. These and the income limits have been approved by a group of representatives appointed by the British Medical Association. They are as follows:

	Income Limit	Quarterly Subscription
Single subscribers	\$2,000 per annum	\$3
Married subscribers	\$2,750 per annum	\$4½
Married subscribers with dependents under 18.....	\$3,500 per annum	\$5

PARIS

(From Our Regular Correspondent)

July 29, 1939.

Compulsory Diphtheria Vaccination

Pasteur said in 1881 at the seventh International Congress of Medicine in London, when he announced the immunization of animals against chicken cholera and anthrax, "I have given to the name 'vaccination' an extended meaning which I hope science will adopt as a tribute to the deserts and inestimable services rendered by one of the greatest men of England, Jenner." Thus Pasteur bestowed on all immunizations the name which Jenner had given to his procedure.

Jules Renault, before the Academy of Medicine, in connection with compulsory diphtheria vaccination, gave an account of the social applications of the different vaccinations. He recalled that prophylaxis against diphtheria was first brought about by means of the combination of toxin and antitoxin after the discoveries of Park and then by anatoxin when Ramon showed in 1923 that a toxin exposed for several months to the action of formal lost its toxicity but not its prophylactic power. The academy had demanded since 1927 that anatoxin vaccination be made compulsory but the law was not promulgated until 1938. It stipulates: "Antidiphtheria vaccination with anatoxin is compulsory in the course of the second or third year of life." France had been preceded by other countries, including Poland, Switzerland and Rumania, in compulsory legislation. However, anatoxin is not generally endorsed. It is well known that it confers immunity under ordinary conditions only on about 98 per cent of the children inoculated. Failure to be effective in the 2 per cent of cases opened the way to criticisms of its efficacy. Nevertheless the repetition of the injection, applied at present six months after the vaccination, permits elimination of even this residual percentage. The law also provides that in cases of war or epidemics the entire population of menaced areas be revaccinated. Anatoxin acts with the same constancy at all age levels. It is not subject to anaphylactic accidents, since it is not a serum. It never induces grave reactions. The accusations made against it in a recent campaign can be utterly rejected, according to Renault and the whole academy.

In France, 2,400,000 infants have been vaccinated. Only seventeen deaths were reported following closely on the heels of vaccination. Of these seventeen deaths, thirteen ought to be attributed to other causes than anatoxin and were simple coincidences. The other four cases were obscure. Obtainable data were uncertain and did not inspire conviction. However, even though mortality in four cases is admitted, the risk of accidental postvaccinal death is reduced to 1 in 600,000 cases. On the other hand, statistical analyses of diphtheria conclusively show that morbidity and mortality have diminished since the general use of anatoxin and that the diminution was proportionate to the frequency of vaccinations. The age of 2 or 3 years was chosen because children enjoy immunity before this time, transmitted no doubt by the blood of the mother. From the second year susceptibility is great and remains so during the school age of the child. According to the requirements of the law, 10,620,000 children are subject to vaccination. Anatoxin vaccination, while compulsory, is rendered free of charge except for those who prefer to consult a practicing physician. Parents who object to compulsory vaccination make themselves liable to prosecution.

Poliomyelitis

Pierre Lépine of Lyons and his collaborators stated before the Academy of Medicine that they believed that the conception of poliomyelitis as due strictly and solely to a neurotropic virus ought to be abandoned and that this disease should be regarded as a general disease with occasional neuraxial determinations. They based their view on observations of a case of epidemic transmission with familial implications. A man aged 28 entered the hospital with the diagnosis of acute angiocholecystitis. He had had diphtheria in infancy complicated by paralysis of the velum of the palate. The disorder for which he was hospitalized had begun with fever, which developed into bronchopneumonia with paralysis of the velum of the palate. Necropsy revealed typical lesions of poliomyelitis. The case, therefore, was one of acute anterior poliomyelitis with exclusively bulbar localization in the classic but exceptional form of Heine-Medin disease. The patient had two young children. Both had manifested slight febrile conditions of benign nature somewhat sooner than their father. Lépine suspected poliomyelitic infection and sought the virus in their stools. One of the children yielded negative results in spite of several tests. The other, however, was found in three successive tests to be the carrier of the virus after inoculation with Macacus rhesus serum. The virus was discovered forty-one, seventy-four and 123 days after the first indeterminate manifestation of fever and would have passed unobserved except for the necropsy performed on the father. Subsequent tests conducted with the same technic revealed the presence of the virus in diminishing quantity.

Lépine wanted to find out how the serum of this child would react in the presence of a poliomyelitic serum and discovered that the virus was strongly neutralized by the serum. He therefore concluded that a child in good health, having shown only a transient and benign infection by poliomyelitis virus, can eliminate the virus in the feces for a prolonged period of time and thus become a carrier of the germ.

Congress for Internal Medicine

The Congress for Internal Medicine was held in the spring in Wiesbaden. About 1,800 physicians attended. Prof. Wilhelm Stepp of Munich in his opening address pointed to the dangers that grow out of the changed mode of living of our time, in particular to the errors committed in nutrition. Its consequences are decreased performance and lessened power of resistance against infections of all kinds. The vitamin authority György demanded that solely the state of highest power of performance and of resistance of the organism be designated by health. Some diseases, such as arteriosclerosis, Stepp continued, are closely connected with errors of the individual mode of living, agitated life with an excessive amount of work, excitement and care, abuse of luxuries such as tobacco, and so on. The subjects for this year's discussions were selected with the thought in mind of keeping Germans fit up to an advanced age. The meetings of the first two days were held jointly with the Society of German neurologists and psychiatrists. Arteriosclerosis was the first main theme and Ludwig Aschoff of Freiburg read the first paper. He adhered to the definition of Marchand given twenty-five years ago at this same place, i. e. designation of the diseases of the vessels due to their being used up as atherosclerosis. The clinician includes other diseases also in the motion of arteriosclerosis: the infectious processes and above all syphilis, the spastic vessel diseases, and nephrogenous and essential high blood pressure. Aschoff contrasts arteriosclerosis with all these diseases of the arteries and calls it a disease due to old age. Concerning the pathogenesis of atherosclerosis, the inhibition

of the vessel wall through the circulating blood was considered. Only the exterior third of the media of the large vessels is nourished by the vasa vasorum, while the inner layers are fed through the lumen of the vessel. The imbibition of calcium in the regions with disturbed nutrition takes place after the deposit of lipoids. For this the slight increase of the lipoid and calcium level in the blood at an advanced age should be held responsible also in endocrine diseases and the like. Although the increase is small, it may lead to extensive deposit throughout the decades. Besides, in an advanced age there is a greater affinity of the tissues to lipoids and calcium salts. Physical factors also influence the place of deposit. The pressure within the vessels is of importance, since there is atheromatosis in the pulmonary artery only in case the pressure of this artery is increased. The significance of the mechanical strain on the vessels follows also from the fact that the places of origin of the intercostal arteries as well as the bifurcation of the iliacs are places of preference; especially strong mechanical vibrations take place there. Among the external influences occupation and nutrition are significant, even though it is not yet known for certain which factors of nutrition, histamine and so on, are important. The use of tobacco is certainly connected with the sclerosis of the coronary vessels, while consumption of alcohol does not favor the formation of atherosclerosis. The constitution should also be mentioned, although in general the external factors are more important.

Walther Frey of Bern, a clinician, reported on the important diagnostic improvements of the last years. As to pathogenesis, the statistics point more and more to the inheritance factor. The influence of nourishment and tobacco is yet uncertain. There is no relation between alcoholism and atherosclerosis. The influence of infections, of nervous strain and of nutrition is questionable. Prophylactically those measures are the most important which promote the circulation of blood through the organs and vessels and which direct the various mechanisms of regulation through which the vascular system protects itself from overloading. Muscular activity, stay in the open air and care of the skin are the best. Therapeutically it remains to be seen whether the tissue structure can be improved through a correction of the endocrine dysfunctions as well as through the use of substances and measures which promote oxidation and the circulation of blood in the tissues (vitamins, chlorophyll, warmth, diathermy, baths).

The clinician Bürger of Leipzig spoke on the results of chemical examinations for age on the blood vessels. There the process of growing old can be observed early. A decrease of elasticity can be observed at the age of 20. The wall of the aorta thickens with age through transformation of its entire structure. Chemical examinations of fifty normal human aortas showed that the cholesterol, lipoid substance and acid soluble phosphorus contents of the aorta increase, while the phosphatides do not.

As a result of his observations on the influence of the nervous system on the circulation of the blood, Otfried Foerster of Breslau reported that, as against the ganglion extirpation in angiospastic conditions of the extremities, preganglionic cutting of the sympathetic is practiced with great success. He pointed to the curative results through bilateral cutting of the splanchnic nerves in essential hypertension. From the discussion it became apparent that the opinions are greatly divided about the importance of alcohol and tobacco in atherosclerosis.

Franz Volhard of Frankfurt on the Main dealt with the treatment of high blood pressure. Lowering of the increased blood pressure will be obtained through lowering the demands on the circulation; in acute cases through venesection, in chronic cases through diet. There is no better expedient for lowering the demands on the heart and vessels than fasting, combined with removal of the liquid part of the diet. Molhard makes regular use of this hunger and thirst treatment in high blood pressure of

acute diffuse glomerulitis, pregnancy-kidney disease and pre-eclampsia. Early diagnosis is important; after six weeks of acute nephritis the changes on the vascular loops of the kidneys become irreversible and the chronic course becomes inevitable. Previous removal of the foci of infection (tonsils) is sometimes necessary. In all chronic forms of high blood pressure fasting represents a sovereign mode of treatment, moderated through the use of fruit and vegetable juice. Only the most serious cases of malignant sclerosis fail to react. Diet poor in salt is important, although it is difficult to carry it through in all its strictness.

The third main theme dealt with focal infection. Pathologist Robert Roessle of Berlin said that to his mind focal infection is a weakened form of a general infection; the most important points of departure are dental granuloma and chronic angina. It is correct to separate focal infection from sepsis, though they are related in essence. Focal infection is to be regarded as a "forme fruste" of sepsis. As Karl Kissling of Mannheim explained in the clinical report following, the connection between chronic foci of infection and certain diseases should be regarded as assured. The following can safely be regarded as focus-caused diseases: 1. Arthritis, acute as well as chronic, including acute articular rheumatism, rheumatic endocarditis, pericarditis, pleuritis, myocarditis, chorea and myositis. 2. Ischialgia in a small percentage of cases and other diseases behaving like neuritis. 3. Heart and vessel diseases, cardiac valve and muscle diseases as far as they belong to the rheumatic types. Perhaps also phlebitis. 4. Nephritis (action of streptococcal toxin after Volhard). 5. Endocrine disturbances, in particular thyroses. 6. Facultative-allergy conditioned diseases, such as urticaria, many eczemas, dermatoses, and perhaps also bronchial asthma. 7. Several chronic subfebrile conditions and eventually also anemias of unknown etiology. 8. Eventually certain anginous (angina pectoris) disorders.

The last theme of the convention was the deterioration of teeth as a sign of malnutrition. Professor of dentistry Euler of Breslau said that about 90 per cent of the milk teeth of children as well as more than 80 per cent of the remaining teeth of adults are found affected with caries; caries in this proportion is likely to have existed for only a relatively short time. The main cause apparently is the change of nourishment in composition and cooking. The share of vegetables is too small, and bread giving teeth enough work is introduced with difficulty.

Examination of Cotton Mill Workers

M. Thiry reported to the Belgian Association of Social Medicine the results of an inquiry made in the glove industry, in which he examined about 310 cotton mill workers. His attention was directed to the number of persons with hypertrophy of the lymph glands and to the frequency in young persons of hypertension. Hypotension is exceptional, while hypertension is common and at times high. In certain cases this hypertension can be connected with pulmonary sclerosis, with which numerous cotton workers are affected. However, this explanation does not suffice when it concerns young persons not yet afflicted with pulmonary lesions causing trouble to the circulation. He discussed modifications in the sedimentation speed.

Occupational Diseases Affecting Engravers

M. Uytendhoeft read a paper before the Belgian Association of Social Medicine on the examination of 270 employees in certain branches of printing, such as engraving and photo-gravure work. The maladies observed spring from three prin-

cial factors: electric arc radiation, acid vapors and cutaneous effects of numerous chemicals, among which turpentine and chromates are mostly to blame.

Leptospirosis at Antwerp

Dr. Van der Walle made a study of a phase of Weil's disease at the Prince Leopold Tropical Institute and published it in the *Nederlandsch tijdschrift voor geneeskunde*. He examined 100 dogs at the Antwerp pound and was able to demonstrate the presence of leptospira antibodies in the blood of forty-four animals. The number of cases in which lysis took place was twice as high for *Leptospira canicola* as for *Leptospira icterohaemorrhagiae*. The percentage of infections increased with the age of the animals. *Leptospira canicola* was cultivated in the kidney of one of the dogs. It was proved that leptospirosis had scarcely any pathogenesis for the guinea pig. Human infection with *Leptospira canicola* is unknown in Belgium.

Aug. 8, 1939.

The Serum Treatment of Pneumonia

Denmark probably has been ahead of other European countries in profiting from studies on the serum treatment of pneumonia recently conducted in the United States. The credit for being in the van in this field is mainly due to Dr. Thorvald Madsen, who is at the head of the State Serum Institute in Copenhagen and who is endowed with a wide international outlook. Since 1935, with the cooperation of his assistant Dr. N. I. Nissen, he has organized a special department in his institute for the bacteriologic and serologic study of pneumonia. It has been calculated that in the fifteen year period 1921-1936 there have been approximately 10,000 deaths from croupous pneumonia in Denmark, and if to these deaths are added those from pneumococcal bronchopneumonia the count against the pneumococcus is heavy. Investigations have shown that types I, VII and III are responsible for about 64 per cent of all the cases of pneumococcal pneumonia, whereas none of the other types play an important part from a statistical point of view.

Dr. Nissen has undertaken a study of 932 cases of pneumonia given serum treatment. Though these cases represented for the most part severe and moderately severe forms of the disease, and though many cases were included in which the dosage of serum was inadequate or it was given too late, the mortality was no higher than 13.5 per cent. Considering that the pneumonia mortality in Copenhagen between 1935 and 1937 among patients not given serum was between 30 and 40 per cent, this 13.5 per cent represents an achievement. In Dr. Nissen's opinion, chemotherapy and serotherapy should become partners rather than rivals, and he is convinced that in the future and in the cases in which the blood stream is seriously infected by pneumococci of the lower types the best treatment will be a combination of chemotherapy and serotherapy. The serum he prefers is rabbit serum the concentration of which is so high that there are from 4,000 to 6,000 units to every cubic centimeter. He has also succeeded in reducing the cost of serum to such an extent that 200,000 units now cost only about 40 kroner (\$8) instead of 350 (\$70).

The Prevalence of Gastric Ulcer

There is evidence in Copenhagen and the provinces of a rise, as formidable as it is inexplicable, in the incidence of gastric and duodenal ulceration, notably in men. The most recent study on this subject comes from the town of Aarhus, where Dr. A. Guldager and Dr. F. Heintzelmann have undertaken a survey of the records of all the hospital cases of ulcer hemorrhages treated in the period 1918-1937 inclusive.

To the question whether gastric and duodenal ulceration has increased in frequency in that period, they answer from an analysis of 341 cases that it has. During these twenty years

the number of hospital-treated cases of ulcer hemorrhage has been more than quadrupled, whereas the population of Aarhus and the total admissions for nonsurgical diseases to the hospital have each increased by only 30 per cent. Most surprising of all is the change in the sex ratio of ulcer hemorrhage. At the beginning of this twenty year period the ulcer hemorrhages were equally distributed between the sexes, whereas at the end of the period there were from four to six men to every woman. As far as women are concerned, there has been no increase in the ulcer hemorrhage rate. No satisfactory explanation is forthcoming of this phenomenon so unfavorable to the male. It was found that the mortality was 16.3 per cent for patients over 50 and only 2.2 per cent for patients under this age, the total mortality being 6.5 per cent (twenty-two deaths among 341 patients).

Of What Do Lupus Patients Die?

Of lupus itself? Rarely! This is the conclusion to which Dr. C. N. S. Gundtoft has come after undertaking a study of the causes of death of the 211 patients who died after attending the skin department of the Finsen Institute in Copenhagen in the last twenty-five years. Of the dead patients, sixty-five were men and 146 were women. Only four men and six women were reported as having died of lupus itself, the average age of the men being 67 and of the women being 51. The average age of the twenty-one men and forty women reported as having died of pulmonary tuberculosis was 36. There were also four men and three women who died of tuberculous meningitis, and one woman who died of miliary tuberculosis. There were also nine men and seventeen women to whose deaths tuberculosis in some form or other contributed considerably.

It is evident from these figures that, while lupus itself usually runs so benign a course that it seldom proves fatal in itself, other manifestations of tuberculosis, pulmonary tuberculosis in particular, play a most important part as a cause of death. It was noteworthy that in about two thirds of all the fatal cases of pulmonary tuberculosis the disease of the lungs became manifest only a short time after treatment of the lupus had been instituted. In these cases the pulmonary disease often ran a rapidly fatal course and thus favored the suspicion that the lupus may have been a cutaneous manifestation of a latent but very serious form of tuberculosis. Among the patients dying of pulmonary tuberculosis it was common to find that the lupus had healed. Indeed, at the Finsen Institute it has become a current saying that, when pulmonary tuberculosis is active, the chances of the lupus being rapidly cured are enhanced. About half (107 patients) died from nontuberculous diseases, which in twenty-four cases were cancers. Heart disease accounted for nine deaths and pneumonia and bronchopneumonia for fifteen. There were also eight deaths due to senile decay, whatever that may mean. These figures suggest that if the lupus patient can avoid death from tuberculosis he has a good chance of living to a ripe old age.

Marriages

CHARLES BURDIS DAVIS JR. to Miss Margaret MacRae Williams, both of Wilmington, N. C., July 15.

WILLIAMS DEAN STEWARD, Augusta, Ga., to Miss Martha Frances Boyd of Chattanooga, Tenn., in June.

TAYLOR C. GILBERT, Dallas, Texas, to Miss Edyth Erhard of Temple in Albuquerque, N. M., recently.

WILLIAM J. KUCEWICZ, Thompsonville, Conn., to Miss Mary Emma Newsome of Arcadia, Fla., recently.

THADDEUS ANTHONY TIMMONS, Lake City, S. C., to Miss Margaret Allen in St. Matthews, July 3.

JAMES GIBSON SMITH, Birmingham, Ala., to Miss Ruth Niskarn in St. Cloud, Minn., in June.

BAYARD M. KELLER, Cuyahoga Falls, Ohio, to Miss Jean Speciman of Williamsheld, June 15.

Deaths

Vernon Lawrence Treynor * Council Bluffs, Iowa; State University of Iowa College of Medicine, Iowa City, 1891; member of the House of Delegates of the American Medical Association from 1934 to 1937 and in 1939; past president and secretary of the Iowa State Medical Society; for many years a member of the board of regents of the State University of Iowa; formerly county coroner; on the staff of the Jennie Edmundson Hospital; president of the Physicians Casualty Association of America; aged 72; died, June 12, of heart disease and arteriosclerosis.

Thomas Richard Sealy * Santa Anna, Texas; University of Texas School of Medicine, Galveston, 1904; fellow of the American College of Surgeons; formerly counselor of the Fourth District of the State Medical Association of Texas; served during the World War; formerly health officer and president of the school board; medical director and superintendent of the Sealy Hospital; aged 59; died, June 15, of cirrhosis of the liver.

William Seevers McDannald, Tenaflly, N. J.; Medical College of Virginia, Richmond, 1909; member of the Medical Society of New Jersey; for many years a member of the medical board of the Englewood Hospital and attending physician in the antepartum clinic of the outpatient department; served during the World War; formerly school physician; aged 65; died, June 23, in Hot Springs, Va., of cardiorenal disease.

Fred Willard Powers, Waterloo, Iowa; State University of Iowa College of Medicine, Iowa City, 1889; in 1905 member of the House of Delegates of the American Medical Association; member of the Iowa State Medical Society; formerly bank president and member of the state board of health; past president of the state board of medical examiners; aged 71; died, June 16, of cerebral thrombosis.

Anson Mayes Cameron, Chicago; Hahnemann Medical College and Hospital of Philadelphia, 1900; member of the Illinois State Medical Society; formerly professor of pediatrics at the Hahnemann Medical College and Hospital, Chicago; served during the World War; aged 65; died, June 20, in Delavan Lake, Wis., of coronary thrombosis and arteriosclerosis.

Frederick James Mann, Darien, Conn.; University of Buffalo School of Medicine, 1893; formerly secretary of the Dutchess County (N. Y.) Medical Society; at one time physician to the city schools of Poughkeepsie, N. Y.; formerly on the staff of the Westport (Conn.) Sanitarium; aged 68; died, June 23, in Berkeley, Calif., of coronary thrombosis.

Joseph Mark Walsh, Rapid City, S. D.; University of Illinois College of Medicine, Chicago, 1905; member of the American Academy of Ophthalmology and Otolaryngology; fellow of the American College of Surgeons; for many years member of the board of education; aged 61; died, June 26, of bronchogenic carcinoma of the lung.

William Frederic Schroeder * Newton, Kan.; Rush Medical College, Chicago, 1922; served during the World War; county health officer; past president and secretary of the Harvey County Medical Society; on the staff of the Bethel Deaconess Hospital; aged 48; was killed, June 12, in an automobile accident.

Edward Oswald Schaaf, Newark, N. J.; Bellevue Hospital Medical College, New York, 1894; Medizinische Fakultät der Universität Wien, Austria, 1896; music composer, arranger and interpreter; aged 69; died, June 25, in the Presbyterian Hospital of uremia, abscess of the liver and diverticulitis of the colon.

Irwin Sherwood Altman, Buffalo; University of Buffalo School of Medicine, 1934; member of the Medical Society of the State of New York; assistant in medicine at his alma mater; aged 29; on the staff of the Buffalo General Hospital, where he died, June 9, of acute nonspecific ulcerative colitis.

William Thomas Sharp, Farmington, Tenn.; University of Nashville Medical Department, 1889; member of the Tennessee State Medical Association; past president of the Bedford County Medical Society and the Marshall County Medical Society; aged 70; died, June 18, of cholecystitis.

Andrew Alexander McKay, Midland, Mich.; Detroit College of Medicine, 1894; past president of the Manistee County Medical Society; formerly on the staff of the Mercy Hospital, Manistee; served during the World War; aged 66; died, June 3, of cerebral hemorrhage.

Spencer Carleton, New York; Columbia University College of Physicians and Surgeons, New York, 1898; formerly associate professor of materia medica at the New York Medical

College and Flower Hospital; aged 65; died, July 11, at his home in Flushing, N. Y.

Robert S. Taggart, New Washington, Ind.; University of Louisville (Ky.) Medical Department, 1893; member of the Indiana State Medical Association; aged 69; died, June 10, in St. Joseph Infirmary, Louisville, of infection of the prostate and renal insufficiency.

Millicent Mary Augusta Cosgrave, New York; Cooper Medical College, San Francisco, 1902; at one time assistant clinical professor of medicine in the department of pediatrics, Stanford University School of Medicine, San Francisco; aged 70; died, June 24.

George Phillips Reynolds * Boston; Harvard Medical School, Boston, 1924; instructor in medicine at his alma mater; formerly secretary of the Suffolk District Medical Society; junior visiting physician to the Boston City Hospital; aged 41; died, June 6.

Isadore J. Pass, Macon, Ga.; University of Minnesota Medical School, Minneapolis, 1932; member of the Medical Association of Georgia; on the staff of the Macon Hospital; aged 30; died, June 9, of injuries received in an automobile accident.

Aaron Levy * St. Louis; Missouri Medical College, St. Louis, 1897; at one time assistant professor of children's diseases, St. Louis University School of Medicine; aged 63; formerly on the staff of the Jewish Hospital, where he died, June 18.

Thomas Lee McDonald * Hope, Ark.; Memphis (Tenn.) Hospital Medical College, 1910; formerly secretary of the Hempstead County Medical Society; aged 50; died, June 26, of injuries received in an automobile accident in Stephenville, Texas.

Ira McKinney * Champaign, Ill.; Chicago College of Medicine and Surgery, 1916; served during the World War; on the staff of the Burnham City Hospital; aged 46; died, June 10, in the Presbyterian Hospital, Chicago, of carcinoma of the penis.

Joseph B. Seaman, Mishawaka, Ind.; Medical College of Indiana, Indianapolis, 1900; member of the Indiana State Medical Association; on the staff of the St. Joseph Hospital; aged 74; died, June 3, of rupture of an aneurysm of the abdominal aorta.

Herbert L. Newell, East Randolph, Vt.; University of Vermont College of Medicine, Burlington, 1886; member of the Vermont State Medical Society; aged 78; died, June 8, in the Gifford Memorial Hospital, Randolph, of acute pancreatitis.

John William Worrell, Pittsburgh; University of Pennsylvania Department of Medicine, Philadelphia, 1881; member of the Medical Society of the State of Pennsylvania; aged 82; died, June 11, in Atlantic City, N. J., of coronary thrombosis.

Louis Sims Oppenheimer, Tampa, Fla.; Louisville (Ky.) Medical College, 1875; member of the Florida Medical Association; past president of the Hillsborough County Medical Society; aged 85; died, June 12, of heart disease.

Adam Hale Oliver, Edwardsville, Ill.; Washington University School of Medicine, St. Louis, 1893; member of the Illinois State Medical Society; aged 74; died, June 1, of chronic nephritis and fracture of a hip received in a fall.

Henry Tipton Byars, Caruthersville, Mo.; Jefferson Medical College of Philadelphia, 1886; past president of the city board of health and formerly mayor; for many years member of the board of education; aged 79; died, June 5.

Carl Lane Cline, Dayton, Ohio; Hahnemann Medical College and Hospital of Philadelphia, 1901; member of the Ohio State Medical Association; served during the World War; aged 62; died, June 22, of chronic pancreatitis.

John Jacob Osterhout, Bellevue, Mo.; Albany (N. Y.) Medical College, 1898; served during the World War; aged 62; died, June 4, in the Veterans Administration Facility at Jefferson Barracks of coronary sclerosis.

Edward Schulz, St. Louis; Homeopathic Medical College of Missouri, St. Louis, 1904; member of the Missouri State Medical Association; aged 68; died, June 28, at his summer home in St. Clair, Mo., of carcinoma.

George William Mengersen, Chicago; Chicago College of Medicine and Surgery, 1909; member of the Illinois State Medical Society; aged 57; died, June 19, of chronic myocarditis at his summer home in Grafton, Ill.

Jacob Siewert Weber * Davenport, Iowa; Rush Medical College, Chicago, 1901; formerly bank president; on the staffs of the Mercy and St. Luke's hospitals; aged 62; was found dead, June 2, of coronary occlusion.

Thaddeus Parker, Broadmoor, Colo.; Michigan College of Medicine and Surgery, Detroit, 1891; member of the Colorado State Medical Society; aged 70; died, June 17, of injuries received in an automobile accident.

Horace N. Abernethy, Charlotte, N. C.; Louisville (Ky.) Medical College, 1894; member of the Medical Society of the State of North Carolina; aged 74; died, June 10, in Denver, N. C., of cerebral hemorrhage.

Oscar Kemper Mohs, San Francisco; University of California Medical School, San Francisco, 1920; member of the California Medical Association; aged 46; was killed, June 11, in an automobile accident.

Ellsmore Stites, Bridgeton, N. J.; University of Pennsylvania Department of Medicine, Philadelphia, 1892; for many years member of the board of health; aged 72; died, June 1, of chronic nephritis.

Robert Albert Warner ☉ Baltimore; University of Maryland School of Medicine, Baltimore, 1895; formerly served with the U. S. Veterans Bureau; aged 67; died, June 7, of carcinoma of the rectum.

Samuel Leroy Rea ☉ Ukiah, Calif.; Cooper Medical College, San Francisco, 1896; past president and secretary of the Mendocino County Medical Society; aged 64; died, June 8, of chronic myocarditis.

William Waddell Meloy, Chicago; Rush Medical College, Chicago, 1897; served during the World War; aged 65; died, June 19, in the Washington Boulevard Hospital of carcinoma of the prostate.

Allyn Cilley Poole ☉ Cincinnati; Medical College of Ohio, Cincinnati, 1887; aged 78; on the staff of the Christ Hospital, where he died, June 27, of cerebral thrombosis and prostatic hypertrophy.

James Richard Thompson, Manchester, Tenn.; Vanderbilt University School of Medicine, Nashville, 1879; aged 91; died, June 12, as the result of injuries received in an automobile accident.

De Witt Clinton Romaine ☉ New York; College of Physicians and Surgeons, Medical Department of Columbia College, New York, 1881; aged 82; died, June 1, of arteriosclerosis.

Thaddeus Walker, Grosse Pointe, Mich.; Detroit College of Medicine, 1893; member of the Michigan State Medical Society; veteran of the Spanish-American War; aged 69; died, June 13.

Archer Clifton Jacobs, Elmore, Minn.; Minnesota Hospital College, Minneapolis, 1886; member of the Minnesota State Medical Association; aged 86; died, June 28, of heart disease.

Francis Albert Scott, Rochester, Mich.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1899; aged 73; died, June 25, of chronic pulmonary tuberculosis.

Samuel Grover Phillips, Denver; Kansas City (Mo.) Hahnemann Medical College, 1910; member of the Colorado State Medical Society; aged 76; died, June 1, of cerebral hemorrhage.

Joseph J. Moncrief, Little Rock, Ark.; Arkansas Industrial University Medical Department, Little Rock, 1897; aged 81; died, June 11, in the Baptist Hospital of coronary sclerosis.

Joseph John Pelletier, Lewiston, Maine; Medical School of Maine, Portland, 1901; member of the Maine Medical Association; aged 59; died, June 4, of chronic myocarditis.

Valentine Trant McGillicuddy, Berkeley, Calif.; Detroit Medical College, 1869; aged 90; died, June 6, in the Alta Bates Hospital, of cerebral hemorrhage and arteriosclerosis.

Grace Melville Bliss Du Vall, Fairbury, Neb.; Central Medical College of St. Joseph, Mo., 1902; aged 59; died, June 17, of chronic myocarditis and bronchopneumonia.

William P. Rothwell ☉ Pawtucket, R. I.; University of Minnesota College of Medicine and Surgery, Minneapolis, 1892; aged 73; died, June 14, in the Memorial Hospital.

John Pompey Thomas, Detroit; Meharry Medical College, Nashville, Tenn., 1928; on the staffs of the Edyth K. Thomas and Parkside hospitals; aged 40; died, June 26.

Lillian Irvine Pollock, Denver; Denver Homeopathic College, 1897; aged 83; died, June 11, of intracapsular fracture of the left hip joint and diabetes mellitus.

Clyde Clifford Winter, Farmington, Mo.; St. Louis College of Physicians and Surgeons, 1906; aged 60; died, June 30, in the Missouri Baptist Hospital, St. Louis.

Amon Peter Flaten ☉ Yuma, Colo.; Rush Medical College, Chicago, 1919; on the staff of the Yuma Community Hospital; aged 48; died, June 4, of heart disease.

Mary E. McClain Neptune, Loudonville, Ohio; Woman's Medical College of Pennsylvania, Philadelphia, 1897; aged 71; died, June 26, of cerebral hemorrhage.

William Hervey White, Akron, Ohio; Western Reserve University Medical Department, Cleveland, 1903; aged 64; died, June 25, in the Akron City Hospital.

Jacob H. C. King, Hot Springs National Park, Ark.; Arkansas Industrial University Medical Department, Little Rock, 1889; aged 78; died, June 5.

Sam H. Cannady, Oxford, N. C.; University of Virginia Department of Medicine, Charlottesville, 1887; aged 72; died, June 22, of chronic nephritis.

Ewing S. Moad, Blue Springs, Mo.; Missouri Medical College, St. Louis, 1882; aged 79; died, June 21, of chronic nephritis and endarteritis obliterans.

Thomas Olearius Whitacre ☉ Bowling Green, Ohio; Rush Medical College, Chicago, 1906; formerly mayor; aged 65; died, June 19, of heart disease.

Henry Elsworth Phares, Shelbyville, Ind.; Hospital College of Medicine, Louisville, Ky., 1897; formerly county health officer; aged 68; died, June 26.

Justus Vanculen White, Decatur, Ill.; Rush Medical College, Chicago, 1900; served during the World War; aged 66; died, June 21, of heart disease.

Walter Harry Ross, Winter Haven, Fla.; Marion-Sims College of Medicine, St. Louis, 1893; aged 67; died, June 8, in the Winter Haven Hospital.

George W. Pearson, Manchester, Tenn.; Vanderbilt University School of Medicine, Nashville, 1882; aged 86; died, June 8, of bacillary dysentery.

James P. Masterson ☉ Mauriceville, Texas; Memphis (Tenn.) Hospital Medical College, 1893; aged 69; died in June of coronary occlusion.

Reuben Newton Mayfield, Seattle; Long Island College Hospital, Brooklyn, 1880; Rush Medical College, Chicago, 1883; aged 80; died, June 17.

Thomas Richardson Morehead, Mertzon, Texas; Dallas Medical College, 1904; aged 64; died, June 2, of cerebral hemorrhage and hypertension.

John Augustine Riley, Chicago; Rush Medical College, Chicago, 1895; aged 71; died, June 20, of cerebral thrombosis and arteriosclerosis.

Evlan Sargent, Moline, Ill.; Northwestern University Medical School, Chicago, 1898; served during the World War; aged 68; died, June 4.

W. P. Roberts, Lexington, Ky.; Pulte Medical College, Cincinnati, 1888; aged 70; died, June 19, of arteriosclerotic heart disease.

Bureau of Investigation

THERMO-MAGNETIC CUSHION FRAUD

W. E. Holder's Device Is Debarred from the Mails

A Chicago concern doing business under the names Chicago Thermo-Magnetic Cushion Company and Holder's Health-Aids, Inc., was debarred from the mails by a fraud order issued against it by the Post Office Department on Dec. 23, 1938. Included in the order were Ruby E. Morgan, secretary, and "Dr." W. E. Holder, president.

This group advertised and sold through the mails a rubber chair cushion containing an electrical unit with connections. It was represented in some of the advertising to "stop the cry

Illustration (reduced) of Thermo-Magnetic Cushion.

of those irritated nerves responsible for the pains of menstruation, of enlarged prostate, kidney and bladder troubles, lumbago, sciatica, etc." Also, this "new and simple method applies deep soothing heat to the organs of the pelvis and abdomen." Further advertising claimed:

"The Chicago Thermo-Magnetic Cushion looks like a regular seat cushion. It can be used anywhere—at home or at the office. It is attractive in appearance with its neat leatheroid covering. Its sponge-rubber construction makes it a resilient and very comfortable seat cushion.

"But, concealed inside, near the top, are two specially constructed Electro-Magnetic Coils. They are so placed as to send Thermo-Magnetic Heat Rays through the Perineum or the soft part between the thighs to the Pelvic Organs.

"This cushion is designed to stimulate and increase circulation of blood and of nerve energy in the Pelvic Region where so many vital organs, including the sex glands, prostate, etc., are located—and where sluggish circulation has such a tendency to occur.

"Congestion or abnormal blood circulation in this area brings about such conditions as backaches, menstrual irregularities and pains in women, prostatic and bladder symptoms in men, lumbago, sciatica, rheumatic pains, etc.

"To all sufferers from any such ailments, and their physicians, this message about the Chicago Thermo-Magnetic Cushion, and the relief it can give, is respectfully addressed.

"Science has long known the beneficial effects of the proper application of heat to various parts of the body. Even in the most ancient times some knowledge of this sort was prevalent. But—they naturally knew nothing then about the extraordinary and far-reaching results that can be accomplished through the use of electricity.

"Diathermy—electrically produced heat—has come to be used throughout the world in the treatment of internal organs of the body which would not be otherwise accessible without operation.

"And recently—electro-magnetic and radio-wave heat has been successfully used to conquer even the dread disease of syphilis, by inducing what is called 'artificial fever.'

"Thus science is discovering more and more ways of utilizing this most ancient of natural healing aids for the benefit of mankind.

"The Cushion is so constructed that just the right amount of Filtered Infra-Red Rays and Electro-Magnetism is provided which will penetrate through cotton, wool or silk garments. The patient receives the benefit of these deep-penetrating, life-restoring Forces without experiencing any discomfort and while fully clothed.

"For all pelvic trouble, nervousness, constipation, or general malaise the Cushion will work wonders. Often headaches can be cleared up within an hour or two. It is a natural aid to circulation, a relief to cold feet and legs, and a preventative of colds and many other illnesses to which mankind is heir."

In the memorandum that Hon. Vincent M. Miles, Solicitor for the Post Office, sent to the Postmaster General, recommending the issuance of a fraud order, he brought out these facts:

That a qualified physician who tested the device found that when used as directed it raised the temperature of the external surface of the skin directly over the heating unit 1½ degrees

above normal; that the pulse rate was not changed and the temperature of the patient taken under the tongue was normal, indicating no rise in body temperature; and the therapeutic effects of the device were essentially the same as those of an ordinary electric heating pad or a hot water bottle containing water heated to 120 degrees Fahrenheit.

That a test of the device with magnets showed that, though there was a slight magnetic field surrounding the heating unit, medical evidence proved that the magnetic effects produced by it exerted no beneficial results whatever on human tissues. It was shown that the small amount of infra-red rays emitted by the cushion in question in the form of radiant energy would be practically stopped by the covering of the heating unit and the leatheroid covering of the cushion itself; and that even if these rays did strike the skin they would penetrate only a very short distance and their effects would be lost in the normal processes of heat regulation carried on by the body through the flow of the blood and lymph.

That the cushion would not and could not remove the causes of all bodily ailments as claimed and would have no value in the treatment and cure of stomach and digestive troubles, rheumatism, lumbago, sciatica, prostatic conditions, colds and neuritis, except possibly for slight palliative effects in some few cases.

That the use of this cushion for the treatment of syphilis would be worse than useless, as it might permit the disease to reach a point where it would be beyond proper care.

The memorandum stated, further, that no physicians were connected with the business, though it had one A. Mercer Parker, who claimed to be a "drugless healer." Parker is listed under "Chiropractors" in the current Chicago telephone directory. In November 1938 a letter bearing his signature was sent out in which he offered to demonstrate to a teacher of singing his "natural corrective methods for relaxing excess tension and relieving irritations," which methods he described as "brilliant and lasting in their results."

From the Solicitor's memorandum one learns also that Parker entered this Chicago cushion outfit in 1937, after W. E. Holder, who had started it in 1936, had run it for a year. In June 1937 a Chicago newspaper reported the incorporation of "Holder's Health Aids, Inc.," to "sell, manufacture electro-medical appliances such as Holder's Thermo-Magnetic Cushion." Holder and Parker were two of the incorporators named.

<p>ACTUAL FACTS</p> <p>Many may dispute the statements in this folder, the onus is on those that do, to prove otherwise.</p> <p>Endorsement for the many claims as to the efficacy of this treatment is given in the hundreds of testimonials I have received. It is FACTS from Sufferers that count.</p> <p>Modern practice of Medicine is still only in the empiric stage, it changes like fashions. Many methods of treatments likewise. The application of the NATURAL FORCES of NATURE has never been improved upon.</p> <p>There are over 20000 of satisfied users in Great Britain.</p>	<p>A SCIENTIFIC EXPLANATION</p> <p>Many will state there is no Electro-Magnetism on account of heat. The explanation is, there is a heating coil and an independent copper coil which produces the Electro-Magnetic force by induction. Get a compass and test it.</p> <p>Although the current passes through both coils simultaneously, one produces heat, the other free electricity — Magnetism. The perineum being the point of highest conductivity and offering the least resistance in the Human Body, the best results are obtained by application to this point.</p> <p>Testimonials from Medical and private users can be seen at our office.</p>
---	--

Reproduction (reduced) of some of the Holder advertising.

In some of the advertising Holder claims that he originated the Thermo-Magnetic Cushion in 1930 at the suggestion of a circle of friends who met regularly in a London club. To quote:

"In this particular group which the writer was a member there were a Gynecologist, M.D.; a Neurologist, M.D.; a Specialist in Rectal Disorders, M.D.; a Oculist, M.D.; a Radiologist; a Osteopath and the writer who is a re-search Medical Electrologist."

Holder goes on to say that when these practitioners had tried out the device in a variety of cases they became enthusiastic over the results, and, to quote further from Holder's careless writing:

"Since that time hundreds of British Medical men have purchased Holder's Thermo-Magnetic Cushion and recommended them to their patients. Up to the present time there are over 20,000 satisfied users in Great Britain and Dominions, there are a few in U. S. A. which have

been purchased by visitors who have brought them back, in fact, I was invited to come to U. S. A. five years ago to supervise the making of the Thermo-Magnetic Cushion but owing to being busy in perfecting my Short-Wave Condensator. I could not leave England, having now perfected that I decided to come to Chicago where the Cushion is being made, therefore, you have the privilege of purchasing Holder's Thermo-Magnetic Cushion at a less price than sold in England."

The form letter from which the foregoing is quoted was signed in facsimile typewriting "Dr. W. E. Holder, Fellow Int. Faculty of Sciences (London)." A search through all available sources failed to show that Holder is a graduate of any medical school in the British Isles or in this country, or that he is licensed to practice medicine anywhere. The high-sounding society of which he claims to be a fellow declared in a letter in which it solicited a nonmedical man in Chicago for membership that it had been "established for the purpose of federating all branches of Science into one united world organization." This was in 1932 and, if the organization had succeeded in its purpose and had made any mark in the world of science, undoubtedly the American Medical Association would have known a good deal about it by this time but has not.

The Chicago man who was solicited for membership received a circular giving the names of the officers of the organization. Strangely enough, the only one who could be found listed in the British "Who's Who" was an American (named as one of the vice presidents), a professor in an Iowa college. An inquiry sent to him brought the reply that he had been a member only a short time and had been able to find out very little about the movement!

On Aug. 10, 1938, the Federal Trade Commission entered a complaint against the Chicago Thermo-Magnetic Cushion Company and A. Mercer Parker, described as "an officer of the company who controls and directs its sales policies and business affairs." Parker and the concern were charged with representing that their device would cure constipation, colds, rheumatism, lumbago, neuritic conditions, stomach and prostate troubles and other ailments. Apparently this case had not been concluded by the time the Post Office Department issued its fraud order against the concern on Dec. 23, 1938, debarring from the mails the Chicago Thermo-Magnetic Cushion Company, Ruby E. Morgan, Secretary, Holder's Health-Aids, Inc., W. E. Holder, President, and their officers and agents as such.

TWO SEX FRAUDS

Two minor but indecent swindles were denied the use of the United States mails last September. One was conducted from Chicago, the other from New York City.

The Chicago concern was promoted by Bernard Moses, who used the trade-styles "Bermo Laboratory, Inc.," and "Bernard Laboratories, Inc." Moses sold through the mails a preparation he called "Retardo," which was claimed to cure premature ejaculation. The stuff was advertised under such claims as "Staying Power Increased. Greater Thrills. Less Disappointment and Embarrassment due to Prematurity." Retardo was found by government chemists to be an ointment containing local anesthetics that was to be applied to the glans penis a few minutes before sexual intercourse.

Moses, who obtained his dupes by advertising in "various publications," claimed to be a registered pharmacist of the state of Illinois. The sale of Retardo was declared to be a fraud and was debarred from the mails Sept. 1, 1938.

The New York swindle in the same field was conducted by one Jacob Weitz, who used among other trade-styles the name "Jacques Products Company." Weitz's preparation was named "Excello-Jel" and, like Retardo, was a lanolin ointment containing local anesthetics. Like it also Excello-Jel was sold as a cure for premature ejaculation. In addition Weitz sold "J. P. Tone-Up-Nerve-Tabs," which was said to be a cure for lost sexual vigor—thus working both sides of the street! The last-named product consisted of tablets containing milk sugar and small quantities of strychnine and zinc phosphide, with minute traces of iron and calcium. On Sept. 15, 1938, the Jacques Products Company was declared a fraud and debarred from the United States mails.

Correspondence

POLIOMYELITIS AND TONSIL OPERATIONS

To the Editor:—For some time I have noted with concern articles which attempt to connect the avenue of infection of poliomyelitis, at present unknown, with the surgical removal of adenoids and tonsils. To foster such ideas, directly or indirectly, which long experience on the part of practically all nose and throat men over the United States in no way bears out, is to do harm to countless children who need tonsillectomy.

Considering that operations for tonsillectomy and adenectomy number possibly one fourth of all major operations that are performed yearly in the country and under all sorts of varying conditions and circumstances, one could well promote almost any idea, however untrue or remote, by citing the occurrence of a few sporadic cases. The removal of adenoids and tonsils, when necessary, is so important in the welfare of children that attempts to raise doubts and issues not clearly proved is to do great harm rather than good. Because a few cases of poliomyelitis occurring in summertime may have appeared after any operation, whatever that operation might accidentally have been, is no reason whatever to raise doubt and fear. If there is an epidemic of poliomyelitis in one's own community, any wise physician under these exceptional circumstances should easily recognize what is the best procedure to adopt. The summertime during the long vacation period is a good time for the removal of tonsils and adenoids in school children and should be consistently encouraged.

HENRY G. LANGWORTHY, M.D., Dubuque, Iowa.

A NEW DIPHTHERIA ANTITOXIN

To the Editor:—Your attention is called to an editorial comment entitled "A New Diphtheria Antitoxin" in THE JOURNAL, July 22, page 326.

This comment discusses results obtained by Pope by means of peptic digestion of diphtheria antitoxic serum and does not give credit to Parfentjev, who first published the description of a successful method of refining diphtheria antitoxin using peptic digestion.

A recent routine batch of diphtheria antitoxin processed by Parfentjev's peptic digest method contained at least 9,000 units per cubic centimeter and approximately 50,000 units per gram of protein. The potency referred to by Pope was 27,000 units per gram of protein.

The antitoxin discussed by Pope has many of the same desirable characteristics as that processed by Parfentjev, because Pope used a method of carefully controlled peptic digestion similar to that previously described by Parfentjev. Antitoxin prepared by the Parfentjev method had been available as "Diphtheria Antitoxin (globulin modified) Lederle," with the approval of the Council on Pharmacy and Chemistry of the American Medical Association, for more than two years before the issue of the Pope article.

Dr. Parfentjev's procedure is described in U. S. Patent No. 2,065,196, issued Dec. 22, 1936. This was referred to by Pappenheimer and Robinson in a paper entitled "Quantitative Study of Ramon Diphtheria Flocculation Reaction" in the *Journal of Immunology* 32:291 (April) 1937, and by Zinsser, Enders and Fothergill in "Immunity—Principles and Application in Medicine and Public Health," fifth edition, 1939, page 172. (Pappenheimer's article was referred to by Pope.)

S. D. BEARD, Pearl River, N. Y.
Director, Lederle Laboratories.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

SUSCEPTIBILITY TO FLEA AND MOSQUITO BITES

To the Editor:—All the fleas and mosquitoes in our neighborhood concentrate on me and rarely, if ever, bite my wife. One of my friends states that his wife attracts fleas only, while he is "eaten alive" by mosquitoes and does not remember ever having had a flea bite. Do you know of any explanation for this?
M.D., California.

ANSWER.—In an article entitled *Flea Antigen in Prevention of Flea Bites*, Cherney, Wheeler and Reed (*Am. J. Trop. Med.* 19:327 [July] 1939) state: "It is well known that there is some form of 'immunity' or resistance to insect bites. California, and particularly the San Francisco Bay region, abounds in fleas which do not encroach on the rights of most of the local population but which are a source of great misery to many newcomers until they acquire an 'immunity.' This usually takes from several months to several years, and in rare instances is never acquired. . . . A similar situation holds true in mosquito districts. Again it is newcomers who suffer most." These authors conclude: "There is definite evidence of some sort of 'immunity' to flea bites, and the fleas' selection of their victims is not a matter of chance."

The nature of this "immunity" is not clear. It is perhaps only analogous to bacterial immunity and is associated with an allergic reaction and a process of desensitization. The situation needs serious study. It is possible to desensitize with flea extracts against the reaction to flea bites, and this desensitization seems to be accompanied by a decrease in the bite rate.

DECAPITATION AND CONSCIOUSNESS

To the Editor:—In the July 10 issue of *Life* magazine are a series of pictures of the decapitation of Wiedman. Can you give me an account of just what processes take place after such an execution? How long do the head and body live after separation? I notice that immediately after the blade falls the body is dumped into a waiting basket; presumably the head is thrown in too. I have seen this in the case of chickens, in which respiratory movements continue for nearly a minute; the body of the chicken jumps about and, in one case, stood up on the feet only to fall again, while the eyes were seen to blink and the mouth to open and close several times as in suffocation. Somewhere I have read of the case in which the victim stood up after the ax had fallen and boxed the ears of the executioner. I would appreciate authentic information on this point. No books seem to mention anything about it.
M.D., New York.

ANSWER.—There has been much speculation as to the possibility of conscious processes going on in the human brain after the head is suddenly separated from the body by the usual processes of decapitation. The only available record of observations to determine the existence or nonexistence of consciousness in a decapitated head seems to have appeared first in the *Républicain orléanais*, June 27, 1905, and is republished in *The Underworld of Paris* by Morain (*The Underworld of Paris: Secrets of the Sûreté*, Alfred Morain, C.B.E., Préfet de Police of Paris, London, Jarrolds, 1931, pp. 300-302). The authenticity of this record is implied by the fact that Morain's attention was called to it by Monsieur Deibler, executioner in chief of arrested criminals.

In this case, according to the report, when the prisoner's head fell into the tray placed before the guillotine Dr. Beaurieux, with the permission of the public prosecutor, took the severed head between his hands and called out the name of the man whose head it was. According to the report, the eyelids opened and the two eyes gave a long stare into those of Dr. Beaurieux. Then the lids fell. A second time the doctor called the name, the eyelids were raised and the eyes stared into those of the doctor. Again they closed. A third time the doctor called the name, but there was no response. The experiment, says the report, lasted thirty seconds, during which time the decapitated head quite certainly preserved conscious life. A similar report appeared at the time in *Le journal*. According to that report, however, Dr. Beaurieux not only called the name of the prisoner but asked "Do you hear me?" *Le journal* indicates that physicians other than Dr. Beaurieux were present and says that they came to the conclusion that vital perception lasted no longer than ten seconds after the execution.

There appear to be no direct experiments on the subject, such as might be done with the aid of the new technic of registering the so-called brain waves. However, the following facts indicate fairly conclusively that conscious processes in the brain of man cease almost simultaneously with the severance of the head from the body:

1. The brain of man is so dependent on oxygen in the arterial blood and the continued removal of carbon dioxide and other wastes by the capillary circulation in the brain that a few seconds of complete inhibition of the heart produces unconsciousness and fainting. Circulation of blood in the brain stops at once with the severance of the head.

2. A blow directed toward any part of the head, even not severe enough to break any bones of the skull or jaw ("the knockout blow") is known to produce unconsciousness of various duration, even without much disturbance of the circulation in the brain, although the most recent investigation of the problem on dogs indicates that the momentary stoppage or slowing up of the circulation in the brain may actually be the cause of this type of unconsciousness. In beheading a man, the jar to the skull and its content from the ax or guillotine crushing or severing the atlas or one of the cervical vertebrae is in all probability as severe as any knock-out blow.

3. The movements of tongue, jaw, facial muscles, eyelids or pupils that may occur after beheading are in all probability due to stimulation of the lower reflex centers in the brain by the state of asphyxia and in no wise indicate conscious processes.

4. In the case of lower vertebrates (birds, reptiles, frogs and fishes) in which the brain is less immediately dependent on the oxygen of the arterial circulation, it is known that ordinary reflexes can be elicited through the brain of the severed head for several minutes after such severance. But the correspondent is mistaken in his description of the behavior of the decapitated chicken. If the head of the chicken is actually severed completely below the medulla, breathing movements stop at once and forever. Irregular muscular movements of legs and wings continue for a few minutes, but the truly decapitated chicken is unable to stand or jump or fly in the accepted physiologic meaning of these terms. These movements in the decapitated body are in all probability induced primarily by asphyxial stimulation of the centers in the spinal cord. If the decapitation in the case of the chicken is improperly made, leaving the midbrain and the medulla still attached to the neck and body, such behavior as described may occur for a few seconds, and respiratory movements really do persist. But this is not true decapitation.

In summary: All available biologic and medical evidence indicates that conscious processes in the human brain cease practically simultaneously with the severance of the head from the body.

DERMATITIS FROM ORTHODICHLOROBENZENE

To the Editor:—I have a case of occupational dermatitis in which orthodichlorobenzene of synthetic varnish is the exciting factor. Can you give me any references to the subject?
F. E. Clark, M.D., Ogdensburg, N. Y.

ANSWER.—In synthetic varnishes containing orthodichlorobenzene, other constituents and in particular the synthetic resin base may be more provocative of dermatitis than the orthodichlorobenzene itself. In the absence of the results of patch tests or other similar diagnostic procedures, final acceptance of orthodichlorobenzene as the exciting factor should not be made. In the somewhat meager literature on the toxicity of chlorinated benzenes, scant reference may be found to any action on the skin. Nevertheless this industrial solvent may be regarded as a source of dermatitis if for no other reason than because of its capacity to remove the normal surface fat of the skin. In this respect its action may be like that of carbon tetrachloride, a somewhat similar chlorinated hydrocarbon. Some synthetic resins entering varnishes are well known irritants of the skin, as described by Schwartz (*Dermatitis from Synthetic Resins and Waxes*, *Am. J. Pub. Health* 26:586, 1936). The toxicity of orthodichlorobenzene is described in the following articles, which in turn contain references to other publications:

1. Medical Research Council Report No. 80, "Toxicity of Industrial Organic Solvents" (His Majesty's Stationery Office, London, 1937), cites the Porton investigation of 1928, which concluded that orthodichlorobenzene was too toxic for use as a paint solvent.

2. Special Development Bulletin No. 18 (1932) of the Dow Chemical Company, Midland, Mich., reports that the toxicity on comparison with carbon tetrachloride is on the order of 2.5 to 1.

3. Zangger (*Arch. Gewerbepath. Gewerbehyg.* 1:109 [Feb. 14] 1930) states that orthodichlorobenzene is less likely to produce

intoxication by inhalation than trichlorethylene. Volatility, however, is not a factor of importance when the cutaneous contact is with the liquid material.

4. Flury and Zernik (Schadliche Gase, Berlin, Julius Springer, 1931) summarize the toxicity of this chlorinated benzene and refer to the work of Koelsch (Handbuch der sozialen Hygiene, vol. 2, 1926) for extensive information.

5. With further reference to dermatoses from synthetic resins, reference is made to the work of Dolgoff (*Arch. f. Gewerbepath. u. Gewerbehyg.* 4:643, 1933).

ATHREPSIA IN INFANT

To the Editor:—A 2 months old baby girl who had been ill about six days had been seemingly doing well on a home-improvised formula of evaporated milk, karo and water. At first the mother thought the child had "the flu," as she began to act fretful and to have a fever and diarrhea. It rapidly became worse and in spite of the use of home remedies (aspirin, castor oil and the like) the fever and diarrhea became much worse. When I first saw the infant she had a rectal temperature of 104.4 F., and was passing liquid greenish foul stools every few minutes. She was apathetic, dried out and ill appearing so was hospitalized at once. On admission, in addition to these manifestations, the rectum was highly irritated and a little prolapsed, there was a severe rash about the rectal area and the navel protruded severely. The blood counts showed hemoglobin 79 per cent, red blood cells 3,450,000 and white blood cells 25,000. Kline and Kahn reactions were negative and the urine was essentially normal. Other physical conditions also were not remarkable. Food was withheld for twenty-four hours, and 5 per cent dextrose (from 150 to 250 cc.) was given intraperitoneally and also 5 per cent dextrose in saline solution (from 100 to 150 cc.) three times a day. The admission weight was 8 pounds 4 ounces (3,742 Gm.). Gradually the baby was given S. M. A. and the amount of fluids administered parenterally reduced, so that in about six days the fever was gone, the rectal area became normal and the stools became formed, yellowish brown and smelled sour. On the seventh day in the hospital the baby had no fever, was taking from 3 to 4 ounces (90 to 120 cc.) of S. M. A. every four hours, looked bright and weighed 8 pounds 6 ounces (3,799 Gm.). She was also receiving orange juice (1 ounce) cod liver oil (two teaspoonfuls) and vitamin B. She was passing from eight to nine stools of a fairly normal appearing type. Her condition continued in just this manner until the eleventh day, at which time the baby was taken home. On the fifteenth day of her illness she was in practically the same state. Her weight was still 8 pounds 6 ounces. She still looked well, had no fever, took her S. M. A., orange juice, cod liver oil and the like and still passed stools as described from eight to nine times a day. A tuberculin test done at this time was also negative. The baby was put on a three instead of four hour schedule. Today, her twenty-sixth day of illness, she weighs 8 pounds 6 ounces, as before. Her condition to all intents is as before except that she passes only from six to seven stools daily. These are formed, are yellowish brown and have little odor. Neither the spleen nor the thymus or any other gland is palpable. Her general condition seems good but she does not gain weight. I have made a diagnosis of athrepsia. Is this correct? Can you suggest any other therapy?

M.D., Ohio.

ANSWER.—The description strongly suggests the possibility of an infectious or parenteral diarrhea which has progressed into a severe nutritional disturbance. The paradoxical reaction to food, stationary weight and frequent stools are all characteristic of athrepsia. A careful physical check-up and urinalysis should be done to rule out the possibility of any parenteral infection. Stools should be cultured to remove the remote possibility of specific bacillary dysentery. The most important phase of the treatment of this condition is prophylactic. Management of the acute stage of diarrhea should include early starvation and the use of milks low in carbohydrate and fat, such as Finkelstein's eiweiss milk or protein milk.

It must be remembered that the athreptic infant does not have the ability to assimilate food properly. The intestinal tract cannot digest and absorb food well. In addition there is a disturbance of mineral metabolism due to the loss of electrolytes in the stools. This leads to withdrawal of mineral from the tissues and plasma with ensuing disturbance of osmotic relationships. This in turn leads to a marked circulatory disturbance with concentration of the blood and decreased volume. A clear understanding of these principles indicates the course of treatment. This includes small feedings of easily assimilated milk mixtures, parenteral fluids and blood transfusions to restore circulatory volume and replenish the supply of electrolytes. A short period of starvation is advisable to begin with—about six hours. During this time small amounts of Ringer's solution, physiologic solution of sodium chloride or weak tea may be given. If the infant cannot take fluids well by mouth or if the tissue turgor is poor, a blood transfusion of about 50 cc. followed by a slow intravenous infusion of 5 per cent dextrose in saline solution should be started. For details of this technic see Brennemann's Practice of Pediatrics (Hagerstown, Md., W. F. Prior Company, Inc., 1936, volume I, chapter XV). If this is not feasible, hypodermoclysis of physiologic solution of sodium chloride should be given twice a day.

The feeding of choice in this condition is human breast milk and every possible effort should be made to obtain it. Small frequent feedings should be used at the start, from 1 to 1½ ounces every two hours. One can start with one half ounce for the first few feedings and increase by steps of one fourth ounce with each feeding. Ringer's solution, saline solution or weak tea can be offered between feedings. After forty-eight hours the amount may be increased to 2 ounces every three hours, and as the infant's food tolerance improves it can be raised so that by the end of one week from 3 to 4 ounces may be given every three hours. In the event that no breast milk is available, protein milk is the next choice. One should follow the same principle and give small frequent feedings, using the approximate ratio of one level tablespoonful of the powder to 2½ ounces of water. Carbohydrates should be added to make up 3 per cent. The following is a sample formula:

Powdered protein milk.....	6 level tablespoonfuls
Water	15 ounces
Carbohydrate in the form of one of the maltose-dextrin combinations	4 drachms

The child should be kept on the protein milk until there is a steady increase in weight. The carbohydrate can be increased to 5 per cent after a few days and the protein milk concentrated to one level tablespoonful to 2 ounces of water. Orange juice can be added during the second week and if not tolerated ascorbic acid can be given. Cod liver oil can be deferred until the infant is on a regular feeding. The breast milk or protein milk feeding should be continued until the infant shows a definite gain in weight and the tissue turgor approaches normal. At this point a gradual change should be made to a diluted whole milk or evaporated milk mixture. One can substitute one feeding a day until the feedings are all replaced. It is best to start with the more dilute mixtures, either 2 ounces of whole milk to 1 ounce of water or 1 ounce of evaporated milk to 2 ounces of water and not more than 3 per cent carbohydrates being used.

RAGWEED POLLEN ON MARTHA'S VINEYARD

To the Editor:—Can you supply me with information on the pollen counts for Martha's Vineyard?

Harold A. Abramson, M.D., New York.

ANSWER.—No pollen counts are available for Martha's Vineyard, but, judging from the proximity of this island to Nantucket Island and Block Island and from the conditions prevailing in the latter, it would seem that Martha's Vineyard could not be recommended as a refuge for those sensitive to ragweed pollen. Ragweed pollen concentrations average heavier on Block Island and Nantucket Island than in Boston and New York City.

XANTHOSIS FROM EGGS

To the Editor:—One of my patients, a white man aged 25 with nervous indigestion, consumes raw eggs regularly as a supplement to his daily diet. He watches his weight and when he notices a loss he uses larger quantities of eggs, sometimes consuming from eight to twelve daily. He recently asked me whether there would be any deleterious effects from this regimen. I recalled that several years ago a patient from a rural area was presented at a medical society meeting who showed a generalized yellow pigmentation from consuming large quantities of raw eggs (I do not recall the amount) over a long period of time. Under ordinary conditions would the regimen followed by my patient be likely to result in such pigmentation? Would from eight to twelve raw eggs a day whipped with milk be likely to result in a symptom of this type? What would be the first area of pigmentation that would act as a warning sign? How long would it take such pigmentation to disappear once it began?

M.D., Louisiana.

ANSWER.—The yellow pigmentation described is probably the condition known as xanthosis, the result of xanthemia (carotenemia). Egg yolks contain large amounts of the xanthophyll pigment beta-carotin, and the consumption of from eight to twelve eggs a day would be sufficient to cause xanthosis in susceptible persons. No ill effects are attributable to this condition.

The regions first affected usually are the palms of the hands and the soles of the feet. The condition described in the patient referred to in the inquiry may disappear simply by limiting the egg yolks to not more than two a day, but it may also be necessary to restrict the intake of the green and yellow vegetables. If this is done, attention should be given to the adequacy of the intake of vitamin A, since beta-carotin is the provitamin from which vitamin A is manufactured in the body.

A satisfactory discussion of this subject is contained in the paper of Boeck and Yater (Xanthemia and Xanthosis [Carotenemia]: A Clinical Study, *J. Lab. & Clin. Med.* 14:1129-1143 [Sept.] 1929).

LATE RESULTS OF HEAD INJURY

To the Editor:—A man aged 21, while playing baseball in midsummer 1938, was struck on the right zygoma by a hit ball. He immediately experienced a warm sensation along the region of the sagittal suture back to the occipital region and transitory dizziness. Whereas he states that he had been normal in every respect up to that time, he has since been unable to concentrate, to carry a thought more than momentarily or to distinguish details when attempting to focus his eyes on objects from the size of a wrist watch to that of a basket ball. Attempts at simple mathematics which he had formerly mastered in high school result in utter failure. Watching passing vehicles gives him a sensation of falling in the direction opposite that of the vehicle's motion, of weakness in both knees and calf muscles, "light headedness," and nervousness which never subsides entirely. Bending over forward and then straightening to an erect posture gives the sensation of falling backward. His blood pressure is 120 systolic, 70 diastolic; the temperature, pulse and respiration rate are normal; urinalysis is negative microscopically and for albumin and sugar; the Wassermann reaction is negative; there has been no loss of weight. The patient appears somewhat apprehensive regarding his general condition but especially concerning his lack of power to concentrate. Responses are somewhat delayed as a result of his inability to command the correct words to express himself and the ready flight of most of his thoughts. There are no external evidences of injury to the head or face and no deformities. The external auditory canals were impacted with cerumen, but its removal failed to influence the condition or to reveal any gross abnormalities. Auditory and visual powers seem equal bilaterally. Rotation produces lateral nystagmus in the direction opposite rotation. There is a suggestion of a Romberg sign, but the patient is aware of his rocking motion, which is principally toward the right. The Babinski sign or its equivalent is absent. Can you suggest some further examinations that may aid in reaching a diagnosis of this condition? Amphetamine sulfate tablets daily in divided dosage for a week afforded relief of the "light headedness" only, but I am reluctant to use such a drug over a prolonged period. Can you suggest therapy that might afford relief for this patient? Do you think there has been any damage to the cerebellum or to the vestibular division of the eighth nerve?

Louis C. Stokes, M.D., Coatsville, Pa.

ANSWER.—The problem is whether one is dealing only with a post-traumatic neurosis or if there also has been some actual brain damage. It is assumed that x-ray examination of the head failed to reveal any bone injury. If he has any actual and constant difficulty in finding words and particularly if he often uses wrong words, one would suspect that there has been some injury to the part of the brain that controls speech. If he is right handed, it would have to be a contracoup injury, since he was struck on the right side of the head. The difficulty in concentration and other subjective sensations are well explained by a traumatic neurosis. If there is any claim for insurance or other compensation in connection with the injury, the supposition that one is dealing mainly with a neurosis would be strengthened.

NERVOUS EFFECTS OF ELECTRIC SHOCK

To the Editor:—What are the probable effects on the sensory nerves and muscles of the arm and hand following a rather severe shock from alternating electric current? The shock was not severe enough to produce a burn but was sufficient to prevent the person from releasing his grasp on the iron bar that conducted the electricity.

C. B. Thomas, M.D., Norwalk, Ohio.

ANSWER.—Alternating current is about three times as dangerous as direct current. If a good contact is made there may be little external evidence at the site of contact, yet fatal results have occurred. When the person is not able to release his grasp, the muscles are in tetany. This may cause injury to the fibers (hemorrhages and fragmentation of fibers). The peripheral blood vessels may be in spasm, and effects of ischemia may become evident. The peripheral nerves may even become degenerated. After severe shocks, cases of disseminated sclerosis and amyotrophic sclerosis have been reported. In any of the complications, objective evidence will be present on examination of the affected part; i. e., anesthesia, atrophy and reaction of degeneration to electrical testing. In peripheral damage per se the prognosis for recovery is usually good.

ANESTHETIC EXPLOSIONS

To the Editor:—Could you give me any information on the relative dangers from explosions of nitrous oxide with ether, ethylene and cyclopropane? I would be interested to know the number of fatal explosions from the use of any of these agents during the last year.

R. K. Finley, M.D., Dayton, Ohio.

ANSWER.—There is a real danger from explosions of nitrous oxide when used with oxygen and ether and with ethylene and cyclopropane. A number of explosions which have occurred are listed in the report of the Subcommittee on Fires and Explosions of the American Society of Anesthetists, Inc. (excerpt from the report of the Subcommittee on Fires and Explosions, News

Letter of American Society of Anesthetists, Inc. 2:3 [April] 1939). Additional information on explosions can be found in the proceedings of the regular meeting of the American Society of Anesthetists, Oct. 20, 1938. However, in all probability this does not represent all the explosions that have taken place. Since it is necessary to use the gas machine in the administration of these anesthetics, precaution must be taken to eliminate the danger of static electricity and also to eliminate the danger of using the cautery or diathermy in close proximity to these agents.

A study of the possibilities of eliminating some of these hazards is being made at the Massachusetts Institute of Technology by Professor Horton.

FACE MASKS FOR LUPUS

To the Editor:—I have recently come across a severe case of lupus erythematosus which is quite refractory to treatment, and I am wondering whether you have any authentic information on recent advances in artificial face masks or plastics. It seems that this patient has used masks which were obtained some ten months ago but which are not at all satisfactory.

J. E. Kaiser, M.D., San Diego, Calif.

ANSWER.—A great many of these masks were used by the French during the war; the Americans have used few of them.

Reconstruction of as much as half the face or more by flaps taken from other parts of the body has been quite satisfactory in the hands of those accustomed to handling this work. It was done in the army for service connected injuries; it is being done now after extensive treatment for cancer, wide cautery destruction for lupus and extensive injuries of other types.

The most satisfactory artificial restorations are being made from a new type of self-vulcanizing rubber latex in which color is introduced into the substance of the rubber. These are glued in place; they are hardly practicable on the cheek or openings into the mouth. This idea was first suggested by A. Pont of the French army, who made them out a gelatin mixture, the soldier heating the gelatin each day, pouring it into the mold and peeling it out.

RATTLESNAKE VENOM

To the Editor:—What are the commercial markets for live rattlesnakes or for the venom?

Rollin M. Falk, M.D., Fall River Mills, Calif.

ANSWER.—About twenty years ago rattlesnake venom was employed in the treatment of epilepsy with more or less success, and quite an extensive literature has been published on this subject. More recent scientific work concerning it has revealed that, irrespective of the possible therapeutic use of rattlesnake or *Crotalus* venom, it is unstable, decomposing rapidly at room temperature, and that furthermore it is almost impossible to prepare a sterile solution of this drug. For this reason rattlesnake venom is no longer employed by rational pharmacotherapeutists and is not to be obtained on the market. In addition, it is interesting to note that the toxicity of venom from different species of rattlesnake varies enormously (Macht, D. I.: *Proc. Soc. Exper. Biol. & Med.* 36:499 [May] 1937).

EQUINE ENCEPHALOMYELITIS AND VACCINATION

To the Editor:—I have noticed recently that investigators at the University of California have developed a vaccine against encephalomyelitis in horses. Also there seems to be some evidence of a transmissibility of this disease to man. Have you any information regarding the use of the vaccine in acute or chronic encephalitis in man?

M.D., Florida.

ANSWER.—An effective vaccine consisting of ground infected chick embryo tissue treated with solution of formaldehyde was developed by Beard, Finkelstein, Sealy and Wyckoff (*Science* 87:490 [May 27] 1938). This product has been shown to be highly effective as a prophylactic vaccine in experimental animals and in an extensive use of the material in horses and mules in the field. This product is only a preventive vaccine. It has no therapeutic value.

It has been conclusively shown that man may be infected with the virus of equine encephalomyelitis. It is possible to prepare a vaccine for use as a prophylactic agent in man, although the low incidence of this disease in human beings at the present time would not justify large scale vaccination. Such a vaccine would be of no use in acute or chronic encephalitis. It is only of preventive value. Moreover, the term encephalitis applies to a large group of etiologic conditions. Specific therapy, if such were available, would depend on an exact etiologic diagnosis in each instance.

Medical Examinations and Licensure

Book Notices

COMING EXAMINATIONS

STATE AND TERRITORIAL BOARDS

Examinations of state and territorial boards were published in THE JOURNAL, September 2, page 966.

NATIONAL BOARD OF MEDICAL EXAMINERS

NATIONAL BOARD OF MEDICAL EXAMINERS: Parts I and II. Medical centers having five or more candidates desiring to take the examination, Sept. 11-13. Ex. Sec., Mr. Everett S. Elwood, 225 S. 15th Street, Philadelphia.

SPECIAL BOARDS

AMERICAN BOARD OF ANESTHESIOLOGY: An Affiliate of the American Board of Surgery. Oral. Part II. Philadelphia, Oct. 14-15. Sec., Dr. Paul M. Wood, 745 Fifth Ave., New York.

AMERICAN BOARD OF DERMATOLOGY AND SYPHILOLOGY: Oral. Philadelphia, Nov. 3-4. Sec., Dr. C. Guy Lane, 416 Marlboro St., Boston.

AMERICAN BOARD OF INTERNAL MEDICINE: Written. Various sections of the United States, Feb. 19. Formal application must be received on or before Jan. 1. Sec., Dr. William S. Middleton, 1301 University Ave., Madison, Wis.

AMERICAN BOARD OF OBSTETRICS AND GYNECOLOGY: Written examination and review of case histories (Part I) for Group B candidates will be held in various cities of the United States and Canada, Jan. 6. Applications for admission to Group B, Part I, examinations must be on file not later than Oct. 4. General oral and pathological examinations (Part II) for all candidates (Groups A and B) will be conducted in Atlantic City, N. J., June 8-11. Applications for admission to Group A, Part II examinations must be on file not later than March 15. Sec., Dr. Paul Titus, 1015 Highland Bldg., Pittsburgh (6).

AMERICAN BOARD OF OPHTHALMOLOGY: Written. Various cities of the United States and Canada, March 9. Oral. New York, June 10. Formal applications must be received before Jan. 1. Sec., Dr. John Green, 6830 Waterman Ave., St. Louis.

AMERICAN BOARD OF ORTHOPAEDIC SURGERY: Boston, January. Applications must be filed on or before Nov. 1. Sec., Dr. Fremont A. Chandler, 6 N. Michigan Ave., Chicago.

AMERICAN BOARD OF OTOLARYNGOLOGY: Chicago, Oct. 6-7. Sec., Dr. W. P. Wherry, 1500 Medical Arts Bldg., Omaha.

AMERICAN BOARD OF PATHOLOGY: Memphis, Nov. 22-23. Sec., Dr. F. W. Hartman, Henry Ford Hospital, Detroit.

AMERICAN BOARD OF PEDIATRICS: New York, April 30 and May 1. Kansas City, Mo., preceding the Region III meeting of the American Academy of Pediatrics. Seattle, preceding the Region IV meeting of the American Academy of Pediatrics. Sec., Dr. C. A. Aldrich, 723 Elm St., Winnetka, Ill.

AMERICAN BOARD OF PSYCHIATRY AND NEUROLOGY: New York, December. Sec., Dr. Walter Freeman, 1028 Connecticut Ave. N.W., Washington, D. C.

AMERICAN BOARD OF RADIOLOGY: Atlanta, Ga., Dec. 9-11. Sec., Dr. Byrl R. Kirklin, 102-110 Second Avenue S.W., Rochester, Minnesota.

AMERICAN BOARD OF UROLOGY: Chicago, Feb. 9-11. (The only examination session to be held in 1940.) Case reports must be submitted not later than November 9. Sec., Dr. Gilbert J. Thomas, 1009 Nicollet Ave., Minneapolis.

District of Columbia July Report

Dr. George C. Ruhland, secretary, Commission on Licensure, reports the written examination held in Washington, July 10-11, 1939. The examination covered nine subjects and included sixty questions. An average of 75 per cent was required to pass. Twenty-three candidates were examined, all of whom passed. Four physicians were licensed by endorsement. The following schools were represented:

School	PASSED	Year Grad.	Per Cent
George Washington University School of Medicine.....	(1936)		79.6
83.6, 83.6, (1937) 79.6, 80.1, (1938) 79.8, 84.6, 89.5			
Georgetown University School of Medicine.....	(1934)		79.6
(1936) 85.8, (1937) 84.1, (1938) 82.9, 83			
Howard University College of Medicine.....	(1938)	82.5, 87.2

Textbook of General Surgery. By Warren H. Cole, M.D., F.A.C.S., Professor of Surgery, University of Illinois College of Medicine, Chicago, and Robert Elman, M.D., Associate Professor of Surgery, Washington University School of Medicine, St. Louis. Second edition. Cloth. Price, \$8. Pp. 1,031, with 559 illustrations. New York & London: D. Appleton-Century Company Incorporated, 1939.

This is another textbook of general surgery designed primarily for the medical student. The material is made up, as is obvious from the text and as is stated in the preface, from lectures in general surgery and the specialties. The authors have succeeded in retaining the fundamental clarity and simplicity necessary for proper teaching. Brevity has been achieved by the omission of technical details and descriptions of operations. As Evarts Graham states in the foreword, it is futile to attempt to make an undergraduate an accomplished surgeon. The book begins with chapters on inflammation and repair and then presents the subjects of sepsis and antisepsis, infections, wounds and surgical methods used in treatment. The chapter on infections and injuries of the hands is brief but clear for such a difficult subject, which is basic not only for surgeons but for all general practitioners. The chapter on fractures, sprains and dislocations is good, as is the one on treatment of the diseases of the alimentary tract. The whole subject of abdominal surgery receives sufficient attention for a book of this size. Much emphasis is placed on diagnosis, pathology and symptomatology and necessarily less on the mechanical surgical intervention. The subject of general anesthesia deserves a more technical detailed discussion than is given. A large number of well chosen illustrations, usually conveying a definite meaning, are included. The reproduction of a photograph of a person who illustrates certain features of pituitary dysfunction and who recently figured in a legal controversy over the scientific reporting of his ailment not only adds zest to the chapter on endocrinology but indicates that this chapter is aptly down to date. This volume will serve best as an adjunct to classroom teaching, but its presentation and simplicity and the excellent bibliography will serve the general practitioner as well. It is somewhat regrettable that the fascinating history of surgery does not receive more space in a book intended for teaching, although some history is of course included. On the whole, as a general and extremely matter of fact textbook on surgery, this is a satisfactory one volume work.

Vaccination contre la sénescence précoce. Par C. Picado. Préface du Professeur Caullery. Paper. Pp. 240, with 44 illustrations. Paris: Librairie E. Le François, 1937.

The author discusses the interesting problems of biology, genetics, comparative anatomy and the latest conclusions as to the therapeutic value of vitamins and hormones. He looks on senility as a disease, which he designates as senescence. Senescence, in his opinion, predisposes to other disturbances and diseases, functional and infectious in nature. A thorough understanding of the functions of the ductless glands will perhaps lead to prevention of premature decline of the organism. He shows that longevity is not related to individual height, that height is only an evidence of continued growth and that duration of life does not depend on duration of growth. Man, among mammals, has the greatest longevity, at times passing the century mark. The book is divided into four parts. In part I is discussed "our liberation from vegetative perennialness," in part II "senescence and the causes which provoke it" (the experiments of Metchnikoff on butterflies and other researches are cited). Part III considers "our invisible metamorphoses," including the relationship of age and chemistry and correlated hormonal cycles; the relation of age and the chemical composition of the blood as determined by Carrel and others is mentioned. Part IV discusses the blood serum as a heterologic antigen. Part V takes up "active immunization against premature old age." Experiments on insects and animals are described. It is proposed to create "antibodies of old age" by vaccinating young animals with the blood serum of aging animals. "It is easy to conceive that the serum of old animals, constituted of more concentrated albuminoids, with different lipoids than those of a young animal, with proteolytic, saccharic and lipolytic

BOOK NOTICES

105

ferments which correspond to the hormonal cycle that the animal traverses in life . . . would be a veritable heterologic antigen in relation to the chemical constitution of the blood of a young animal of the same species." This is not rejuvenation of the aged but immunization of the young and a form of preventive therapy against old age. The book contains interesting chapters on dwarfism and gigantism and the development of secondary sex characteristics by the transplanation of organs. Hypothyroidism and hyperthyroidism are considered. The hypophysis on gigantism and infantilism are considered. The transplantation of organs is well discussed. The book will be found interesting reading to those who desire to be abreast of the latest teachings of the value of ductless gland therapy.

Recent Advances in Chemotherapy. By G. M. Findlay, C.B.E., M.D., D.Sc. With a foreword by C. M. Wenyon, C.M.G., C.B.E., M.B., Director-in-Chief of the Wellcome Bureau of Scientific Research, London. Second edition. Cloth. Price, \$5. Pp. 523. Philadelphia: P. Blakiston's Son & Co., Inc., 1939.

The first edition of this book appeared eight years ago, prior to the discovery of chemotherapeutic agents which were effective in the treatment of acute bacterial infections. Therefore it necessarily was for the most part devoted to a study of the action of chemical agents on helminthic, protozoal and spirochetal infections. The new edition covers a wider field, and more especially by virtue of a rather loose interpretation of the definition of chemotherapy. It represents a fairly successful attempt to present concisely as much as possible of the recent advances made in chemotherapy in its broader sense. In this respect the book is commendable. From the standpoint of the general practitioner, much of the material is either of little interest or of limited practical application. This is particularly true of much of the extensive discussion of pharmacodynamics, which is included at the expense of omitting the details of methods of therapeutic application. The author, however, presents the various drugs considered in an orderly manner on the basis of their historical and chemical development. The latter method of developing the discussion for each new drug somewhat lessens the selection of one preparation in preference to its related predecessor. In this respect the book should prove of especial interest and information to the medical profession. The author has preserved a commendable style of presentation and has exercised critical judgment in his summary statements. The reader must remember that the use of many of the chemicals suggested for trial in the treatment of various diseases should be postponed until sufficient clinical evidence is available by which to judge their merit.

Surgical Anatomy. By C. Latimer Callander, A.B., M.D., F.A.C.S., Associate Clinical Professor of Surgery and Topographic Anatomy, University of California Medical School, San Francisco. With a foreword by Dean Lewis, M.D., Sc.D., LL.D. Second edition. Cloth. Price, \$10. Pp. 858, with 819 illustrations. Philadelphia & London: W. B. Saunders Company, 1939.

In the foreword Dean Lewis declares that gross anatomy is now a sterile field for research but that the importance of gross anatomy to the clinic has not changed. To the surgeon gross anatomy is of paramount and permanent importance. Constant advances in surgical technic necessitate revision in anatomic textbooks designed for surgeons. The need for such works is demonstrated by the widespread popularity which this text-book has gained in its comparatively brief existence. Standard traditional treatises on gross anatomy do not change much from edition to edition. However, surgery, which is the clinical approach to anatomy, constantly demands reorientation and reemphasis of previously established concepts. In fulfilling this aim, this volume comes close to the mark. A considerable amount of contemporary material has been incorporated, as is evidenced by the recent dates on many of the illustrations. It is pleasing that, although new additions are numerous, the volume has not been increased in size. Subjects which have been the foci of attention in the past few years are reemphasized, such as lumbar sympathectomy for hypertension, diaphragmatic hernia and operations for the relief of chronic backache associated with disease of the intervertebral disks or the ligamentum flavum. The arrangement of the book is on a topographic basis. The descriptions begin with the scalp and cranium and continue in descending order to the foot. Each

section is complete unto itself as far as nerves, vessels and relationship to adjoining structures are concerned. No fault can be found with the anatomic detail or its method of presentation. The illustrations are clear and practical, and few fail to be excellent. The weaker portions of the book and the sections which invite the most criticism are the clinical aspects, such as the selection of optimal technic and indications. It is surprising that no mention of transurethral prostatectomy is made although both the suprapubic and perineal methods are described. The omission of simple drawings to illustrate the various types of gastric operations, usually known under the names of their innovators, will confuse the tyro. A diagram of the circle of Willis, which is always a tax on the student's memory, could also be included with profit. This forms a good reference book for the complex detail required by the surgeon in order to understand in practical fashion the task before him. The direct linkage of the anatomic structure with the clinical approach adds zest to an otherwise dry subject. Many of the illustrations combine surgical technic with clear anatomic portrayal advantageously. There is no reason why this book should not continue to serve the student and practitioner of surgery.

Minor Medical Operations for Senior Medical Students and Recently Qualified Practitioners. By Kenneth Harris, M.A., M.D., F.R.C.P., Physician, University College Hospital, London, and Edith Harris, M.B., B.S., D.P.H. Cloth. Price, 7s. 6d. Pp. 198, with 41 illustrations. London: H. K. Lewis & Co., Ltd., 1938.

This little manual is designed for the practitioner who may be distant from help and is called on to perform minor procedures unaided. The young physician is apt to forget the practical points he has been taught in medical school when he is brought face to face with the problem of tapping the pleural cavity or giving an intravenous injection. The authors place proper emphasis on the minutiae. They describe pleural punctures of iodized oil are considered; they warn the doctor himself to beware of infection when he examines throats. They are practical enough to know that the suitable vein in the antecubital fossa is the palpable one and not the tiny visible one which seems tempting but betrays the operator by collapsing when suction is applied. Their precautions in nursing care with regard to quiet and order bespeaks a thoughtful personal experience. In general the procedures are the same the world over, but there are some specific situations which apply particularly to the British scene such as notes with regard to chimney openings and registers which are not so conspicuous in the United States. A correction should be noted with regard to the scarlet fever blanching test, which requires the use of page 156. A valuable addition to the section on intravenous fluids is suggested in the following. Throughout the larger children's hospitals in the United States this procedure has been greatly simplified by the use of the small veins of the ankle, elbow and even fingers and scalp. The arm or leg is fastened to a padded board by broad bands of adhesive tape. An incision is made across the course of the vein which permits the vein to be picked up and a cannula inserted and fastened. Transfusion of blood or other fluids is carried out with the usual gravity apparatus. The cannula may be left in situ for several hours for repeated use if desired. On the whole the book will find its greatest usefulness to senior medical students and the practitioner largely dependent on his own resources who has had little experience with methods which should have been acquired in a well rounded internship or apprenticeship.

Classified and Annotated Bibliography of Sir William Osler's Publications (Based on the Chronological Bibliography by Minnie Wright Blogg). Edited by Maude E. Abbott, B.A., M.D., LL.D. Second edition. Cloth. Price, \$2.25. Pp. 163, with 2 illustrations. Montreal, Canada: The Medical Museum, McGill University, 1939.

None of Osler's friends could be surprised at the enduring interest in his writings, though even the most intimate have always been astonished by their quantity and variety. On his seventieth birthday Osler himself wrote of Miss Blogg's original compilation, 1919, it "brought the thrill of the day when I saw revealed the utter shamelessness of my life, a bibliography of my writings extending to 740 articles." What would he say of the present work, which records more than 1,500 separate items to the credit of what he called his "ink-pot career"?

A revision of the classified bibliography in Dr. Abbott's "Osler Memorial Volume," 1926, of the International Association of Medical Museums, this edition supplies a complete index to the titles of his publications. They are arranged in seven classes: natural science, pathology (comparative and human), clinical medicine, literature (history, biography), education and medical profession, public welfare and volumes edited. In each class the arrangement is chronological. The supplementary addenda include the indiscretions of Osler's impish pseudonym, "E. Y. Davis." A useful and revealing volume, well produced.

The Student's Handbook of Surgical Operations. By Sir Frederick Treves, Bart., G.C.V.O., C.B. Revised by Cecil P. G. Wakeley, D.Sc., F.R.C.S., F.R.S.E., Senior Surgeon to King's College Hospital, London. Sixth edition. Fabrikoid. Price, \$5. Pp. 563, with 246 illustrations. New York: Paul B. Hoeber, Inc., 1939.

The popularity of this practical little manual on surgical procedure has probably diminished somewhat since its inception, because of the vast growth of surgery and the number of larger treatises which have appeared on the subject. It is hardly possible to revise a book of this type to bring it completely down to date. Only a few examples are necessary. It is now many years since the Billroth-Mikulicz operation for partial gastric resection was considered the method of choice, yet this method is the focus of description. Mention is not made of the various Polya types of gastric resection which are now widely used or of the use of living fascial suture in the repair of hernia. Such shortcomings, however, are chiefly in the field of major surgery, which students are not expected to know thoroughly. This book is of course written for the English student and as such is expected to be different from that used by the American. Some of the clearest and most practical descriptions available are in this little volume. The technic of tracheotomy, with all the pitfalls that may beset the operator, is presented clearly and concisely. For a brief presentation of surgical technic, indications for operation and choice of method this small volume accomplishes all that can be expected.

Endocrinology in Modern Practice. By William Wolf, M.D., M.S., Ph.D., Endocrinologist to the French Hospital, New York. Second edition. Cloth. Price, \$10. Pp. 1,077, with 176 illustrations. Philadelphia & London: W. B. Saunders Company, 1939.

In this edition Wolf has included a considerable amount of data which has become available since the publication of the original volume. There has been, in addition, a revision of many of the sections in accordance with the more recent progress in endocrinology. Wolf has made a sincere attempt to furnish the physician with a book on clinical endocrinology which contains a wealth of information in an assimilable form. The book is constructed for the convenience of the reader and includes for this purpose many practical features. The clinical descriptions are systematic and adequate, and at the end of each chapter there is a table which summarizes the contents of the chapter. In addition to discussions of the endocrine diseases there are numerous chapters on the relation of bodily disorders to glandular function, such as surgical and orthopedic diseases, nervous and mental diseases, and diseases of the liver, kidney and cardiovascular systems. The section on endocrine diagnosis is an excellent one and contains data which are ordinarily difficult for the physician to procure, such as height and weight tables, interpretation of laboratory observations, bone age readings, bio-assays and tests for endocrinopathies. At the end of the book there is a table of symptom diagnosis which is quite complete. It is unfortunate that the quality of the book is somewhat marred by the inclusion of a certain amount of unscientific material. The author's discussions are also sometimes uncritical on certain phases of glandular disturbances, especially etiology and physiology, in which he admits concepts which active investigators have abandoned or disregarded. The paragraphs on treatment are at times unreliable, since they may include obsolete methods. Wolf persists in retaining the antiquated armamentarium of "desiccated gland" preparations which modern endocrinology has definitely rejected. The elimination of such material and a keener evaluation of the recent endocrine literature would materially enhance the value of the book as an aid to the physician in his understanding and treatment of glandular diseases.

The Nineteen Thirty Eight Mental Measurements Yearbook of the School of Education, Rutgers University. Oscar Krisen Buros, Editor. Cloth. Price, \$3. Pp. 415. New Brunswick: Rutgers University Press, 1938.

The School of Education of Rutgers University has made a survey in the past of the literature on tests and testing. The need for a yearbook in this field has been quite apparent for some time past and the present volume is an attempt to survey the field for 1938. Tests of educational achievement, capacity and intelligence, research and statistical methodology and recent testing programs which came out during that year are all listed in the present volume. Nothing but editing is contributed by the School of Education, for the comments on the included material are culled from the regular review of the tests in the current scientific literature. It is a valuable source book for those who are doing mental testing.

Surface Anatomy. By W. E. Roberts, M.R.C.S., L.R.C.P., Hon. Demonstrator of Anatomy, University of Sydney. Foreword by A. N. Burkhitt, M.B., B.Sc., Professor of Anatomy, University of Sydney. Cloth. Price, 7s. 6d. Pp. 93, with 40 illustrations. Sydney, Australia: Angus & Robertson Limited, 1937.

This is a brief book on topographic anatomy, with especial attention to surface markings. The illustrations are reproductions of photographs and as such are supposed to offer the natural body contours. Some of them are mediocre and no better than line drawings. The intent of the book is excellent, but more and better illustrations are needed. In a book obviously intended for medical students, omission of pelvic illustrations is a serious fault which sharply curtails its value as an anatomic reference.

Klinische Endokrinologie: Ein Lehrbuch für Ärzte und Studierende. Von Arthur Jores, Dr. med. habil. Paper. Price, 27 marks. Pp. 356, with 91 illustrations. Berlin: Julius Springer, 1939.

Because of the tremendous amount of data published in recent years on endocrinology, it is most difficult to obtain a thorough knowledge of the scientific developments in this field unless one has participated actively in experimental investigation. Dr. Jores has been active in experimentation on the various phases of glandular physiology and the application of this work to the clinic. His evaluation of the clinical aspects of glandular diseases is therefore based on a sound foundation of scientific principles. His textbook is constructed on the concepts developed recently in the laboratory and inherits little of the obsolete material which has been handed down in a routine manner for many years in textbooks on clinical endocrinology. The subjects are discussed systematically, concisely and thoroughly. Under the heading of each gland there is discussed in adequate detail the anatomy, physiology, pathology and clinical manifestations of the various glandular disorders and their treatment. At the end of each chapter there is a special summary on therapy, with the preparations of that particular gland. The author's judgment is sound. There are excellent illustrations and reproductions of photographs throughout the book and useful tables of the modern commercial endocrine products. It is noted with gratification that the antiquated "desiccated gland" armamentarium, which has been retained in many textbooks even in recent years, is omitted. The bibliography is extensive and is nicely classified for reference work.

202 Common Household Pests of North America. By Dr. Hugo Hartnaek. Fabrikoid. Price, \$3.75. Pp. 319, with illustrations. Chicago, Illinois: Hartnaek Publishing Company, 1939.

This is a compilation of information published in various languages, particularly German, concerning household pests, the total number of pests discussed in the book being 202. Heretofore there has been no one book in which somewhat detailed information concerning such a large group of household pests could be found. There is a need for readily available information in order that the problem presented by these pests may be better understood and more effective methods of control possible may be found. The author first directs attention to rats and mice, pointing out their habits, the damage they do to property and to public health and suggesting various individual and community methods of control. Other pests discussed are birds, pigeons, roaches, crickets, earwigs, beetles, ants, moths, flies, mosquitoes, bedbugs, ticks and spiders. The damage done by

these pests is generally emphasized. The problem is one of major hygienic and economic importance. Their menace is present in the office, factory, store or home, and even when one lies down to sleep. The author believes that too much is expected of chemical exterminators. He is cognizant of the information which the government has made available to the public but feels that there remains some indifference on the part of the government in the matter of control. He knows of no better way to solve the problem than to apply and practice the rule of L. O. Howard, which he prints above Dr. Howard's signature opposite the title page and which he analyzes in the closing pages. Howard's rule is as follows: "When the economic entomologist confronts an emergency problem, it is his duty to bring measurable relief as speedily as possible. At the same time he must begin studies looking forward to natural and therefore comparatively costless control."

Penny Marsh, Public Health Nurse. By Dorothy Deming, R.N. Cloth. Price, \$2. Pp. 266, with illustrations by Dorothea Warren. New York: Dodd, Mead & Company, 1938.

A well written and interesting story of a graduate nurse who decides on a public health nursing career. The reader follows Penelope Marsh from private duty nursing, through a period of work with the Visiting Nurse Association, to the special course of study in the graduate school of a university. While the book is a novel relating the experiences and adventures of one nurse, it makes an eloquent plea for the public health branch of nursing service. The book will be especially enjoyed by the nurse in training as well as the young women in college and senior high school who are planning a nursing career. The physician will find this a splendid volume to recommend to his families whose daughters have expressed a desire for information about nursing.

Sbornik trudov posvyashchenny LV-letiyu nauchnoy i uchebnoy deyatelnosti zasluzhennogo deyatelya nauki professora G. I. Turnera. [Collection of Works Celebrating 55 Years of Scientific and Pedagogic Activity of G. I. Turner.] Cloth. Price, 13 rubles 50 kopecks. Pp. 419, with illustrations. Leningrad: Izdanie Voenno-Meditsinskoy Akademii R. K. K. A. Im S. M. Kirova, 1938.

This small volume is dedicated to 80 year old G. I. Turner, the founder of the chair of orthopedics in the academy. The contributions are by the members of the academy and deal with orthopedics.

The International Cancer Research Foundation. Report of Activities During 1938. Paper. Pp. 157. Philadelphia, [n. d.]

This volume is an annual publication which summarizes the investigations of this organization during the current year. It is primarily of interest to those who are concerned with cancer research. The progress of each investigation is described and the original articles arising from such work are carefully tabulated. The organization paid grants of more than half a million dollars during 1938, and between 35 and 50 per cent of the funds were allotted outside the United States in accordance with its by-laws. The funds are used for experimentation and not for building or equipment, although the foundation can accept gifts or contributions for the latter items. The organization was founded in Philadelphia June 8, 1932, and since that time has been responsible for much investigation into the causes, prevention, control, relief and cure of "those diseases . . . commonly called cancer."

You and Heredity. By Amram Scheinfeld. Assisted in the Genetic Sections by Dr. Morton D. Schweitzer, Research Geneticist, Cornell University Medical College, New York. Cloth. Price, \$3.75. Pp. 434, with 75 illustrations, including 4 color-plates. New York: Frederick A. Stokes Company, 1939.

The author of this book writes on heredity, as he puts it, "from the outside looking in"; that is, from the point of view of a layman peering into the laboratories of the scientists. He has, however, carefully guarded his accuracy by free consultation with numerous scientific authorities, and the result is an easily readable yet accurate discussion of the present knowledge of human heredity. The two chapters on the inheritance of musical talent, which constitute an original genetic study, are most interesting and clearly demonstrate the failure of many human qualities to manifest readily identifiable hereditary characteristics. It is pleasing to find some commonly credited misbeliefs accurately handled, such as the idea that the entire hair can turn suddenly white. In listing the twelve diseases

which take the largest toll of life in the United States yearly, the year from which the figures are taken should be stated, since their order changes from time to time as is well known. In speaking of the inheritance of cancer, some reference might also be made to the work of Maud Slye, even though her work relates to the inheritance of cancer in mice rather than to human cancer. The book contains the answer to numerous questions propounded to doctors, such as the advisability of cousin marriages. It may be enthusiastically recommended to the public and to physicians alike.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Malpractice: Supposed Injury to Recurrent Laryngeal Nerves Attributed to Tonsillectomy.—On Aug. 28, 1930, Dr. Davidson, one of the defendants, removed the tonsils of Sylvia Daniels, then 13 years old. Three years later her father, her mother and a guardian of the child appointed for the purposes of the suit sued the clinic at which the operation had been performed and certain physicians who had taken part in it for alleged malpractice.

The plaintiffs alleged that in performing the tonsillectomy the defendants were careless and unskilful and so cut the vocal cords and nerves that control the vocal cords or the organs that control the voice, or infected them or caused them to be infected, in such a manner as to cause the permanent loss of the child's voice. They complained, too, that the operation was performed when the patient was known by the defendants to be suffering from an infection of her throat, commonly known as a cold. The case was not tried until January 1935, more than four years after the operation. The jury returned a verdict in favor of the plaintiffs, but on June 5, 1936, on motion of the defendants, a judgment was entered in their favor notwithstanding the verdict. The plaintiffs thereupon appealed to the Supreme Court of Washington.

A trial court, said the Supreme Court, is not warranted in entering a judgment notwithstanding the verdict of the jury if there is evidence, or reasonable inference from evidence, to sustain that verdict. If the evidence is conflicting, and reasonable men may differ with respect to it, then only the jury can decide. In passing on a motion for a judgment notwithstanding a verdict, the court must assume the truth of all evidence in favor of the party in whose favor the verdict was rendered and must draw from it all reasonable inferences favorable to him.

In the present case, the patient's mother testified that her daughter had a cold but that Dr. Davidson refused to operate and did not operate until after the patient had recovered from it. Two of Dr. Davidson's office assistants testified that when the patient came for the operation her voice was merely husky, as if she had a cold. Dr. Davidson himself testified that when the patient came to him for the operation her voice was husky, and his records showed that it continued so, although it improved, after the operation. Various witnesses testified that previous to the operation the patient had "a beautiful, fine, normal singing voice, and after the operation she was never known to sing or speak above a whisper." On the issue of the loss of voice, therefore, the jury, said the Supreme Court, was warranted in finding for the plaintiff.

Anticipating that the defendants would contend that the patient's whispering voice was due to a growth on the vocal cords, the plaintiffs introduced early in the trial one Dr. Thomas Ratigan, who, although a general practitioner, had removed as many "as thirty pairs of tonsils in a morning." Dr. Ratigan testified that he had examined the patient's throat and found no growth. The patient, who had been treated by no less than twelve surgeons and laryngologists since the operation, however, testified on cross-examination that they told her that there was a growth. On motion of the defendants, the court appointed two specialists to examine the throat. They agreed that there

was a small growth on each of the patient's vocal cords that prevented the cords from coming together. These growths, one of the court-appointed experts testified, were the cause of the patient's whispering voice. Nevertheless, said the court, although it seems incredible that these expert witnesses would testify that there were growths on the vocal cords if there were none, the jury had the sole right to weigh their testimony against that of Dr. Ratigan and the jury evidently believed Dr. Ratigan.

Although the original complaint had charged that the vocal cords or the nerves that control the vocal cords had been cut, it was subsequently amended insofar as it undertook to describe the manner in which the cords or nerves were severed. As a matter of fact, all expert witnesses who testified, including Dr. Ratigan who testified for the plaintiff, declared that it was impossible in a tonsil operation to cut the vocal cords or the nerves that control them. A tonsil snare such as is used in a tonsil operation could not be made to pass the epiglottis and enter the larynx or cavity in which the cords were located. One expert, however, qualified his statement by testifying that the nerves controlling the vocal cords could not be cut unless the patient was anatomically abnormal, but there was no claim that the patient in this case was abnormal.

The plaintiffs' expert, Ratigan, testified that in his opinion the whispering voice of the patient was the result of the operating physician's pulling so hard on the tonsil "as to separate the nerve from the muscles which control the voice." As tending to prove that the operation was performed in a rough manner, the plaintiffs introduced evidence to show that the patient had a hemorrhage two or three days after the operation, another one several days later and a third on the eleventh day, and Dr. Ratigan testified that three hemorrhages occurring in a period of seven or eight days after an operation were so unusual as to indicate that there had been a rough pulling or stretching. Ratigan admitted that he had never seen a tonsillectomy result in a permanent whispering voice and he did not know of any instance recorded in the medical literature in which it had done so, but he had heard of such a case. The physician who operated and three other experts called to testify on his behalf had never heard of a tonsillectomy causing a permanent loss of voice nor had they ever seen a report of any such a case in the medical literature. In their judgment it was impossible to rupture a recurrent laryngeal nerve which controls the vocal cords by pulling on a tonsil.

The vital and decisive issue in this case, however, said the court, was not whether the nerve *could* be separated from the muscles by pulling on the tonsil but whether it actually had been separated in any manner. There was no evidence whatever in the record that the recurrent laryngeal nerves, which control the vocal cords, were actually separated from the muscles of the larynx or were injured in any way. On the other hand, there was indisputable evidence that they were functioning on the day of the trial. Dr. Ratigan himself admitted that if the nerve was separated from the muscles it would leave them paralyzed. The two medical experts summoned by the court stated that on their examination the cords moved both on breathing and on an attempt to speak. This showed that the cords were not paralyzed and were functioning properly. Dr. Ratigan admitted that the only circumstance that indicated that the tonsils had been pulled sufficiently to tear the laryngeal nerves from the muscles of the larynx was the loss of voice, which he could not explain in any other way.

There was a complete lack of evidence, said the Supreme Court, that the nerves controlling the vocal cords had been severed. On the other hand, there was indisputable proof that that could not have been the case. The trial judge was warranted, therefore, in the opinion of the Supreme Court, in finding that there was not a scintilla of evidence to show that the recurrent laryngeal nerve was severed from the muscles controlling the voice. Dr. Ratigan's testimony to the effect that solely because the patient had lost her voice he believed the nerves had been severed from the muscles they controlled was not sufficient evidence on which to predicate a judgment against the physician.

For the reasons stated, the judgment of the lower court in favor of the physician was affirmed.—*Steen et al. v. Polyclinic et al. (Wash.)*, 81 P. (2d) 846.

THE AMERICAN RHEUMATISM ASSOCIATION

Sixth Annual Meeting, held in St. Louis, May 15, 1939

DR. LORING T. SWAIM, Boston, Secretary

Considerations Bearing on the Treatment of Arthritic Patients: President's Address

DR. RALPH PEMBERTON, Philadelphia: The arthritic patient is abnormal not only because of deviations within his joints but also because of deviations within his body elsewhere, more or less open to modification. Systemic rest is acknowledged to be the most useful single basic factor in treatment of both great types. Use of "rest," however, is not to be interpreted as a generic panacea for patients with arthritis. It is brought forward rather as a comprehensive, though fragmentary, method of approaching that betterment of function, in many systems of the body, which makes toward a so-called reversal of the arthritic process.

I believe that, in attempting to evaluate the influence of focal infection, the conditioning factors which make infection operative or otherwise must be equally evaluated if the conclusions are to have any significance. To state that, in a given series, removal of infection is unsuccessful may be simply to state that removal is unsuccessful under conditions such that it could hardly be expected to be otherwise. Great injustice may thus be done to the significance of removing infection if it is viewed apart from its real setting: surgically rather than biologically. Removal of infection is often not so complete as supposed. In few syndromes is nutritional imbalance more to be observed. Atrophy of bone, subvitaminosis, faulty hemopoiesis, altered plasma proteins and tissue edema are common spectacles.

Dogmatic allocation of hypertrophic arthritis to age and trauma alone leaves unbridged a philosophic chasm into which many arthritic patients are falling. Among other evidences indicating systemic disturbance, Dandurand and Scull have recently observed reducing bodies other than dextrose in the blood in hypertrophic cases in amounts significantly higher than in normal subjects.

The point of view from which the observer regards the arthritic scene is all important. To him who learns arthritis through bacteriology, few other phases of medicine may seem to touch it. To the pathologist the microscope alone reveals what is worthy of notice. To the practitioner, basic considerations may seem futile since his patients await relief from pain and want it now.

Successful therapy cannot be achieved by means of any alleged panacea or by means of such platitudes as "good hygiene, fresh air and keeping the bowels open." It can be frequently achieved, however, on the basis of a systematic and directional attempt at readjustment of all the dislocated physiologic processes accompanying and largely characterizing the disease. By the same token, the future may hold some single remedial agency which will reach to or near the heart of the oak but we are not yet in possession of it. Perhaps gold will prove as valuable to the patient in his body as it has proved to be in his pockets. Whether we like it or not, we must today face the fact that, lacking that final illumination of arthritis, we are definitely expected to use in the half light all such well considered measures as are available to us. At last analysis the care of arthritic patients as a whole falls on the general practitioner. He properly takes his therapeutic cue from those studying the disease and unless a reasonably wide angled and, above all, a coordinated program is presented to him he cannot be blamed if he turns from academic negativism to the samples sent him by a drug house. To know how to utilize the components of significance of deficiencies or surfeits, to recognize and correct them, to discover an infectious or other morbid nidus, to understand whether and when to remove it, to reeducate the patient toward his problem, to adjust his somatic and local mechanics, in sum to "equilibrate" the arthritic patient and treat him as few sufferers from other diseases are treated constitutes, in my opinion, at least an approach toward a specific therapy which must be experienced to be understood.

There is at the moment a real danger that in our separate quests for the cause of arthritis we are losing some perspective in the cause of arthritis. A chief purpose of this paper is, therefore, to present two objectives: (1) avoidance of the exclusive outlook in this vexed field and the maintenance of a balanced perspective toward all deviations presented by the patient with arthritis; (2) recognition that effective therapy often depends on coordinating the influences of many physiologic processes and that utilization of these influences can be achieved only by those actually desirous of bringing this about.

Menopause Arthritis

Dr. FRANCIS COOLEY HALL, Boston: A review of the literature indicates considerable disagreement regarding the existence or the nature of menopause arthritis, whether due to thyroid or to ovarian gland deficiency or both or neither; whether characterized merely by joint and muscle pain, or whether this is followed by true pathologic changes in the joints. These joint changes are considered to be hypertrophic in nature usually, but some authorities believe that both types can occur.

A study of seventy-one women castrates presenting symptoms of arthritis beginning a few weeks after castration seems to indicate that muscle and joint symptoms (arthralgia) can occur as one of the menopause symptoms and can be controlled, like other menopause symptoms, by adequate estrogenic therapy, except in the presence of infection, excessive physical fatigue, trauma, or excessive emotional disturbance. Control of symptoms may require from 10,000 to 20,000 rat units of estrogenic material a week for six weeks, followed by smaller doses for a varying duration of time. These patients with arthralgia are a condition often indistinguishable from early rheumatoid (hypertrophic) arthritis, for the two conditions may have in common idiosyncratic onset, morning pain and stiffness (worse after sleep),

even slight swelling of the joint and limitation of motion, and elevated sedimentation rate. Fifty-three of the seventy-one cases I am calling arthralgia, because it cannot be proved that true arthritis was present. Of forty adequately treated, 70 per cent were almost entirely relieved of joint and muscle pain by estrogenic therapy. The others responded to a lesser degree.

Eighteen of the seventy-one castrates not only had arthralgia but showed definite signs of true arthritis of either type or mixed types. Estrogenic therapy controlled flashes, sweats and arthralgias and appeared to control the arthritis in many instances.

The evidence suggests the possibility that we are observing different stages of one process going on in the joints, the manifestations depending on the intensity and duration of the irritant, and the end result being hypertrophic arthritis in most cases but the end result being modified by overuse or disuse of the joint. The irritant would appear to be the excessive amount of anterior pituitary hormone in the absence of and due to the absence of ovarian hormones.

Menopause arthralgia, and perhaps menopause arthritis, is a distinct entity due primarily to lack of estrogenic hormone and can be controlled by adequate therapy.

DISCUSSION

Dr. WILLIAM K. ISHMAEL, Oklahoma City: The relation of the various phases of the ovarian cycle in women to arthritis is unknown, but clinical observation certainly indicates that the two are in some way connected. To attempt control of the arthritis with various fractions of the ovarian hormones requires considerable knowledge of the nature and effects of the various principles at hand. My experience with the use of estrogenic materials in the treatment of rheumatism appearing during the menopause and in female castrates who were well before castration and whose symptoms have followed the castration follows closely that reported by Dr. Hall. I also have concluded that the results from treatment in these cases depend largely on the dose and method of administration of the estrogenic materials. It is essential that the body receive the substance in as even a flow as is possible and for this reason I have employed an attempt to provide still further delay in the absorption. In those materials which are contained in an oily solution, I have been administering the substance with 10 cc. of the patient's own blood. Work is now being done to establish this fact of delayed absorption when blood is added to a fat soluble substance before injection. In addition to the possible effect of the delayed absorption of injected materials, the injected blood also exerts the usual effects of autohemotherapy, which has been reported to be of benefit in the treatment of the complications of the menopause. In searching for some satisfactory method of treatment of those climacteric types of arthritis that failed to respond to the estrogen therapy alone, it was decided to incorporate autohemotherapy and fever along with the injections of the estrogen complex. It was gratifying to note that many of those who had failed to respond to the estrogen complex alone did respond to the combined autohemotherapy and estrogen remission was materially reduced in all climacteric cases. Exact figures are not yet complete on this series, as the number of cases treated is too small to justify the drawing of any conclusions at this time.

Dr. LORING T. SWAIN, Boston: I have seen many cases such as Dr. Hall described, with increase of symptoms before menstruation and increase of the arthritis immediately after pregnancy and at the menopause. A woman aged 32 had typical rheumatoid arthritis before she was married. Since 1932 she had had gradual progression of the rheumatoid arthritis in the knees, feet, hands and elbows. Menstruation had been rather scanty always. She was married in 1934, became pregnant in 1935 and was quite well during the first pregnancy. The baby died during delivery. There was a tremendous emotional upset and the joints became again acutely inflamed. Menstruation was more scanty. She was pregnant again in 1936 and the joints again were better. A son was born and the joints again became inflamed three months after delivery. She became pregnant again in 1938 and the joints were again better but not as well as the first time. The baby was born in December 1938. Prior to the last pregnancy we studied the urine and examined

for estrogen. Before and during pregnancy estrogen was present. Dr. Charles Lawrence, who studied this case with me, reports "She showed just before delivery a low normal value for prolans and estrin. The first assay after delivery showed a positive prolans and a negative estrin, and all assays since then have shown negative prolans and negative estrins. It is of course quite normal for the prolans to drop fairly sharply after the pregnancy but what seemed to me significant was the rapid disappearance of estrin. . . . It seems to me that she probably has an imbalance similar to that encountered at the menopause, a definite insufficiency of estrin with, in all probability, intermittent excess of prolans." The estrogen was again balanced in January 1939, and I quote from his letter: "It is definitely certain that her joints are a good deal better and her arthritis to some degree at least is bettered for estrin." At the present time (May) her arthritis is definitely better and she feels well for the first time in years. Another case studied since October 1937 was one of typical rheumatoid arthritis. The patient came to the hospital with an acute anemia and a sedimentation rate index of 1.03 and a basal metabolism rate of minus 3. The joint condition began in 1933. Her menstruation was irregular. In 1934 she had a repair of the cervix and removal of cysts for leukorrhea. Since 1935 menstruation had been painful but there had been no discharge since the operation. Shoulders, wrists, ankles and knees had been swollen and painful. In November 1937 she had a gastric upset with no particular effect on the joints. In December 1937 she had an acute emotional upset with definite effect on the joints. In January 1938 she had tonsillitis. In February 1938 the tonsils were removed with slight improvement. In March we started her on 2,000 rat units of progynon-B and the joints were definitely better. At the present time she finds she can control the amount of pain in the joints by the use of progynon taken once a week, and the objective signs in the joints have improved steadily.

DR. RUSSELL L. CECIL, New York: Several years ago Dr. Archer and I reported fifty cases of menopause arthritis, and at that time the criticism was made that we were simply complicating the picture by inventing a new name for a disease which after all was typical hypertrophic osteo-arthritis. Now the syndrome which we described was really a subdivision of hypertrophic osteo-arthritis occurring at the menopause in middle aged overweight women, with pain in the knees, fingers and lumbar spine. They had hypertrophic changes, Heberden's nodes, and so on. With reduction of weight and mild physical therapy they improved. At that time, fifteen years ago, we did not know so much about the factor of gland therapy. I must confess, however, that theelin and progynon (which seem to be rational therapy) have given me rather disappointing results. In looking back over my cases for two or three years it seems to me that I have had to depend more on physical measures, physical therapy, diet and reduction in weight than on endocrine therapy. There is no more troublesome type of arthritis to treat successfully than that occurring in middle aged women. We are inclined to call these patients psychoneurotic, but the more one sees of them the more one becomes convinced that their pains are genuine.

DR. ROBERT B. OSGOOD, Boston: I have been watching some of these cases of Dr. Hall and want to give testimony that the relief in certain cases has been dramatic, especially in the arthralgic type. I think he has been careful in the control experiments by giving one group an injection of nothing but oil and the other an injection of progynon.

DR. WALTER BAUER, Boston: I should like to ask Dr. Hall why, if overactivity of the anterior pituitary in the castrate so regularly produces arthralgia, one does not encounter this type of arthralgia more regularly in the physiologic menopause?

DR. EDWARD F. HARTUNG, New York: The effect of estrogenic substances in these cases is still one more form of constitutional therapy. It is treatment of an associated condition and surely not of a basic cause. One might in the same way interpret the effect of iron and a great many other factors of constitutional therapy which are known to be of value in these cases.

DR. PHILIP S. HENCH, Rochester, Minn.: A number of different things are meant by those who use the term "menopause arthritis." By it some simply refer to atrophic arthritis

which comes on about the menopause, others simply mean hypertrophic arthritis which appears near the menopause. Still others, however, consider "menopause arthritis" to be distinct from either atrophic or hypertrophic arthritis, to be a definite and separate entity with specific clinical and pathologic characteristics of its own. But though many writers have made inferences as to its supposed pathology and have presumed that it was a villous synovitis which terminates in bony and cartilaginous reactions essentially similar to those of ordinary hypertrophic arthritis (osteo-arthritis), none of the proponents of this supposed syndrome have ever given any proof as to its pathologic identity. Until this is done, "menopause arthritis" will continue to have a most uncertain status and the term should be discarded in favor of the more correct but much less definite expression "chronic arthritis appearing in women about the menopause." When one observes the notable ameliorating effect which pregnancy exerts in some cases of atrophic arthritis, one cannot escape the notion that the endocrine glands may have much to do with articular lesions. To date my own results with theelin therapy have been disappointing and I do not believe we are yet in a position to advocate such therapy as a practical procedure. Those who do so are under considerable responsibility. In the first place, the daily cost of these products is still considerable, perhaps as much as \$1 a day. Theelin is a potent material, and aside from its questionable beneficial effect on joints it may have certain unwanted effects otherwise. The fact that jaundice has the same ameliorating effect that pregnancy exerts in cases of atrophic arthritis makes me believe that the potent factor (which is probably common to both pregnancy and jaundice) is not a strictly female sex hormone nor is it bilirubin. I do not believe that theelin or any other strict female hormone is the potent common denominator. My own assays of hormones do not as yet indicate any consistent abnormality in the concentration of estrogenic hormone in cases of atrophic arthritis. But it is intriguing to realize that bile salts, some of the sex hormones, vitamin D and cholesterol (which increases in the blood during pregnancy) all contain the phenanthrene nucleus. Perhaps the antirheumatic factor, the effective antiarthritis agent for which we are all hoping, likewise contains this chemical nucleus.

DR. JACOB S. KOMINZ, Rochester, N. Y.: I have treated a small number of these menopausal cases with small doses, 2,000 units, of theelin and found little change in symptomatology. Then I gave 5,000 units twice a week and at first there was definite improvement which the patients reported. No mention was made to the patient that the dosage was increased, and after a little while the patients definitely reported improvement. The fact that the normal menopausal case has no control is another point to consider. The diminution in endocrine substance in the normal case is gradual, whereas in the surgically castrated stage it is sudden.

DR. M. H. DAWSON, New York: I should like to utter a word of caution with regard to the use of large doses of those endocrine products which may have possibly a carcinogenic effect in certain instances. In the Presbyterian Hospital we recently observed the development of a cancer of the breast in a patient who had received large doses of such an endocrine product. The breast was surgically removed and the pathologist reported that there was evidence of generalized epithelial proliferation in addition to the frank carcinoma. I think it is generally agreed that small doses of these endocrines are probably without harmful effects; but the use of large doses over a prolonged period would seem to be at least a questionable procedure.

DR. JOHN D. CURRENCE, New York: I think the endeavor on the part of some to place menopausal arthritis as a separate disease entity is one that will not hold water because in Dr. Hall's series there are definite infectious cases with high sedimentation rates, and cases of osteo-arthritis type. I think the main thing to be considered, as Dr. Hartung brought out, is that we must use estrogenic substance where it is indicated, and the amount that we must use is the amount indicated in the individual case. Certainly there can be no tried rule for the amount of deficiency in estrogenic substance, no more than in the amount of anemia in the case. Whether based on the patho-

logic classification of Nichols and Richardson or on whatever classification any clinic may use, the therapy must be individualized on a constitutional basis rather than hope for specific remedies for any given classification.

DR. FRANCIS C. HALL, Boston: In answer to Dr. Bauer's question about the occurrence of arthritis at the physiologic menopause, I believe that it does occur. I can say that it is more apt to be due to overactivity of the anterior pituitary due to estrogenic lack rather than to estrogenic lack alone. I believe it is purely an imbalance. I believe that most of these patients with arthralgia alone, and even with arthritis that come at the menopause, would get well anyway. There are patients who get well with all sorts of treatment because they are going to get well anyway. I think it is desirable that we learn something about the pathology of this condition. It seems to me as I watch these different groups that one merges into the other. The rheumatoid is indistinguishable from early osteo-arthritis but I do not feel the condition is anything more than a chronic joint irritation due to physical trauma. I do not think we need to say that it is rheumatoid or osteo-arthritis in the sense that it is specific. I have been quite conscious of the possibility of carcinoma developing from estrogenic therapy and have kept it in mind. So far there have been no cases of carcinoma from the use of estrogenic substances in the cases I have. I have stopped treatment whenever I could. Many of these people have temporary imbalance. Most of the patients, once they are relieved, are willing to stop; the fear of arthritis has disappeared. I use doses that vary. Castrates require larger doses than those with arthralgia at the physiologic menopause. Many of those will get well if given no more than 2,000 rat units weekly. They will begin to show improvement in a month. They will do better on larger doses. In the castrates I think that 10,000 rat units should be used twice a week. I have always tried to stop it after a while. In a high percentage of cases that is possible.

Sulfur Metabolism and the Effect of Sulfur Administration in Rheumatoid Arthritis

DR. R. H. FREYBERG, W. D. BLOCK, PH.D., and M. F. FROMER, B.S., Ann Arbor, Mich.: This study, at the Rackham Arthritis Research Unit, University of Michigan Medical School, was conducted primarily to answer two questions: (1) Is there a fundamental abnormality of sulfur metabolism in patients with rheumatoid arthritis? and (2) Does the administration of sulfur have a beneficial effect on the sulfur metabolism, or reflected sulfur metabolism, in rheumatoid arthritis?

Patients with typical rheumatoid arthritis in different stages and degrees of activity were fed the same constant, relatively low sulfur diet and distilled water. After a period of adjustment to this regimen, twenty-four hourly collections of urine were analyzed for nitrogen, total sulfur and all partitions of sulfur. After a control value of sulfur elimination had thus been obtained, large amounts of colloidal sulfur were administered intravenously, intramuscularly and orally, and sodium thiosulfate, and in one case also sodium sulfate, was given orally. In this way the effect of these sulfur containing medications, administered in different ways, was observed. To test the ability to detoxify indole-like substances by the formation and elimination of ethereal sulfates, thymol was administered orally, first separately and later at the time sulfur was administered. Suitable control periods separated the experimental periods. Urine and feces were analyzed for cystine before and at different times after sulfur administration. Normal persons were fed diets identical with those of the patients and studied in precisely the same manner.

The results show no important difference in the amount of sulfur eliminated or the way in which it was excreted by the arthritic as compared to normal individuals. The injection of colloidal sulfur affected the metabolism and excretion of sulfur in patients with rheumatoid arthritis in the same way as it did in normal individuals: When injected intravenously the sulfur excretion in all but one patient increased by amounts considerably greater than the amount of sulfur injected; when injected intramuscularly, the sulfur excretion in every arthritic patient was increased by amounts much greater than the amount injected. Thus the injection of colloidal sulfur actually created a deficiency of sulfur. Obviously, then, this method of treat-

ment could not be expected to prevent or diminish a deficiency of sulfur in the body if such deficiency existed. Injected sulfur was eliminated chiefly as inorganic sulfate; there was no important increase in the conjugation of sulfur and hence no benefit could result by conjugation of toxic substances. Sulfur given orally in colloidal form and as sodium thiosulfate affected the same changes in the arthritic as in the normal individual; there was no increase in conjugation of sulfur. Thymol was readily conjugated with sulfuric acid by the arthritic patients and the controls similarly, thus indicating no impairment of this detoxifying mechanism and no need for sulfur medication on this account. Our analysis of finger-nails showed no changes in the cystine content after sulfur medication. No evidence of sulfur deficiency or abnormality in sulfur metabolism was found to exist in patients with rheumatoid arthritis. The data of this study reveal no biochemical or metabolic indication of need for, or benefit from, sulfur medication in the treatment of rheumatoid arthritis.

DISCUSSION

DR. BEN D. SENTURIA, St. Louis: My own work done over five years ago and limited, however, to the determination of total urinary sulfur and its partition is well in accord with the conclusions of the authors. After I found that there was no sulfur deficiency or abnormal sulfur metabolism in these patients, the continued use of sulfur was based on what appeared to be a nonspecific effect. The studies of Dr. Freyberg and his associates may indicate the nature of the nonspecific effect. It was noted that after the intramuscular administration of colloidal sulfur there occurred a marked increase in the output of total sulfur, as much in some instances as 200 per cent of the amount injected. It would be of extreme interest to know what the total nitrogen elimination was in order to determine the nitrogen-sulfur ratio for this period. Possibly the increase in sulfur came from an increase in protein catabolism resulting from the colloidal sulfur administration. I should like to ask what the total urinary nitrogen was for that period in which the marked increment in sulfur excretion occurred; also whether the authors feel that their investigations preclude the possibility of a nonspecific effect from intravenous and intraglutal injections of colloidal sulfur. Finally, let us hope that with the publication of Dr. Freyberg and his coadjutors' instructive experiments such unwarranted statements as "sulfur deficiency," "derangement of sulfur metabolism," "increased sulfur catabolism," "sulfur-hungry tissues" and "deficiency thiopexy" in rheumatoid arthritis will vanish from the literature.

DR. J. ALBERT KEY, St. Louis: I used sulfur in the beginning. I did not like it because it had to be given intravenously or intramuscularly, and occasionally it caused a thrombosis of the vein. I did not notice any difference between the group that got sulfur and those who did not, so I stopped using it. Before we accept new drugs for the treatment of chronic arthritis we should follow them over a period of years on a group of patients and, if possible, we should have studies like this of Dr. Freyberg and his co-workers. Unfortunately, there are few institutions that have facilities for this type of work, but to me this paper is the swan song of sulfur.

DR. WALTER BAUER, Boston: Dr. Freyberg and his colleagues have shown conclusively that the administration of sulfur is deleterious and not beneficial to the mystical sulfur deficiency of rheumatoid arthritis. The supposed sulfur deficiency has served as one of the arguments for using sulfur therapy in this disease. Each newly proposed antirheumatic drug should be similarly investigated as soon as possible. If this were done more often, many new forms of therapy would be quashed before gaining sufficient popularity to become an expensive, useless luxury for the all too poor rheumatoid arthritic patients. In our clinic our experience with sulfur has been limited but disappointing. Dr. N. R. Abrams followed fourteen patients over a period of two years. These fourteen patients had been under observation from one to five years before therapy was instituted. No one of them showed any objective improvement following the intravenous administration of large doses of colloidal sulfur. Fifty per cent of our patients were subjectively improved. Such improvement never lasted more than three months. In only two instances were the sedimentation rates reduced, and this effect did not persist. I think Dr.

Freyberg's results are so clearcut that we can all feel that we are not neglecting our rheumatoid arthritic patients if we do not administer sulfur.

DR. ISADORE PILOT, Chicago: Dr. Reed of Chicago has for some time been studying the sulfur partition and sulfur balance in a larger series of cases than Dr. Freyberg presented and his figures are almost identical, showing no great difference in the normal partition and the total sulfur values in the urine in the normal as well as the rheumatoid type of arthritis. Dr. Reed had his normal and rheumatoid arthritis cases on tremendous doses of vitamin D, from 100,000 to 150,000 units, his chief purpose being to study the physiologic effect of these large doses on normal and rheumatic individuals. The sulfur values in the urine were increased in the arthritic as compared to the normal; apparently there is some difference in the handling of sulfur in the arthritic as compared with the normal. Whatever therapeutic significance there may be in connection with vitamin D I am unable to say. At any rate our work is confirmatory of Dr. Freyberg's studies.

DR. BERNARD I. COMROE, Philadelphia: Our results at the University of Pennsylvania were similar to those of Dr. Freyberg and his co-workers. During the course of hundreds of analyses of nails for cystine content we found no marked difference among arthritic and nonarthritic patients. However, in a small group of carefully controlled patients with rheumatoid arthritis, 20 per cent were markedly improved both subjectively and objectively following parenteral sulfur therapy; an additional 30 per cent were moderately improved. This may be entirely a nonspecific reaction due to the protein which is present in most preparations of colloidal sulfur.

DR. H. M. MARGOLIS, Pittsburgh: While the circulars and advertisements from some pharmaceutical manufacturers are today urging the physician to follow the lead of those who have reported excellent therapeutic results with sulfur in rheumatoid arthritis, Dr. Freyberg and his co-workers show that careful metabolic studies in a group of rheumatic patients reveal no deviation from normal in the metabolism of sulfur. They show that the concentration of sulfur, in its various forms, in the blood of patients with rheumatoid arthritis is essentially the same as it is in normal control individuals. They show, furthermore, that if a deficiency of sulfur in the tissues existed it could not be remedied by the administration of sulfur, since it is excreted about as fast as it is injected parenterally, or ingested. How, then, explain those results which have been reported by occasional observers who have felt that the administration of sulfur to patients with rheumatoid arthritis has resulted in benefit to those patients? I am inclined to believe that the given "percentage" of cases reported to have benefited from the administration of sulfur improved during the administration of sulfur but not as a result of it. There is no questioning the psychologic effect of an injection—of any type of injection—in certain arthritic patients. And I believe that the beneficial effect ascribed to sulfur may be more correctly ascribed to some favorable psychogenic influence of the injections or to the well known tendency to spontaneous temporary remission in the severity of arthritic manifestations. Several years ago I stated unequivocally in a publication of mine that our experience with sulfur was altogether unsatisfactory; that we never noted any beneficial effect from its administration. And yet I am aware that many physicians are still employing sulfur as the chief, if not the sole, therapeutic remedy for their arthritic patients. About a year ago I sent a questionnaire to the members of our association inquiring about their experience with sulfur therapy, as well as some other therapeutic measures. More than a hundred were good enough to answer this questionnaire. All but a very few of those that answered our questionnaire had either discontinued the use of sulfur altogether or were using it without much confidence in its value. It appears that there are several geographic spots where sulfur therapy still holds a place of some importance in the therapeutic regimen, but elsewhere it does not. How can we most effectively broadcast what little rational basis there is for the hope that anything can be accomplished through the use of sulfur in the treatment of arthritis?

DR. R. H. FREYBERG, Ann Arbor, Mich.: We were surprised that the sulfur excretion increased more than the amount of colloidal sulfur injected. To explain this, we thought that per-

haps the intramuscular injection of sulfur might have caused muscle breakdown which would contribute sulfur for elimination. To provide so much sulfur, however, the necrosis of quite a large amount of muscle would be necessary. This should then cause a corresponding increase in nitrogen elimination. No appreciable change was observed in the nitrogen excretion during these periods. To study this possibility further, one subject was injected intramuscularly with a medication which contained no sulfur but which caused essentially the same amount of change in the muscle at the site of injection as did colloidal sulfur. The results indicate that no important change in sulfur elimination occurred; hence we feel that muscle breakdown cannot explain the large sulfur excretion observed. It is possible that sulfur has a "nonspecific beneficial effect," as suggested by one of the discussers. The studies I reported this morning were designed to answer certain specific questions regarding sulfur metabolism and in an effort to detect any way in which sulfur could be beneficial. We have no information concerning "nonspecific effects." I am in agreement with Dr. Key, who so well stated in his discussion that if sulfur therapy is beneficial to patients with rheumatoid arthritis its effect must be accomplished in some mysterious way.

Further Observations of the Use of a High Fat Diet in Gouty Arthritis

DR. L. MAXWELL LOCKIE and ROGER S. HUBBARD, Ph.D., Buffalo: In 1935 a paper was published describing results obtained when a diet high in fat was fed to patients with gouty arthritis. The results could be considered under two headings: the effect on the blood uric acid and the effect on the symptoms of the patients. The effect on the blood uric acid resembles fairly closely the effect of such diets on normal patients described by Harding and others; increases in the blood uric acid values were usually observed after the diet had been instituted and continued for a minimum period of about five days. The effect on the symptoms was striking.

Since this paper was presented, five more experiments have been carried out. The results are essentially similar to those obtained earlier, but certain irregularities in the observations have become noticeable in the more extended series. The most important of these irregularities have been connected with the symptoms. While an exacerbation of the disease has failed to occur in only one instance, a patient who was studied for five days, the time that has lapsed before the symptoms developed has varied from two to sixteen days. Since both extreme periods were noted in studies on the same patient, it is evident that an explanation for the variations cannot be readily suggested. Another finding in these experiments, which was not reported previously, was an increase in temperature which occurred in the majority of the patients after they had been placed on diets high in fat. This frequently reached 102 F.

When diets high in fat are ingested by patients with gouty arthritis, an acute attack of the disease usually develops. This exacerbation is not closely related to measurable changes in the blood uric acid which frequently result when such diets are given.

DISCUSSION

DR. PHILIP S. HENCH, Rochester, Minn.: The authors have made three propositions: (1) that a high fat diet is often harmful to gouty patients, (2) that it is so consistently harmful as to provide a provocative test that is useful in the diagnosis of gout, and (3) that a diet rich in carbohydrates is distinctly helpful. The first proposition, namely, that a high fat diet is often harmful, seems to be strongly suggested not only by the observations of Drs. Lockie and Hubbard but also by others. A few years ago when we were treating infections of the urinary tract with a ketogenic diet I observed a frequent, though not a consistent, provocation of acute gouty arthritis in cases of quiescent gout. My experience with gout seems to indicate that just after an acute attack the patients are temporarily "immune" to another attack for a short time at least. Assuming that the attacks in Dr. Lockie's patients were really over, it is interesting to note that the high fat diets were able to provoke attacks within one to two weeks of a previous attack, that is, in the supposedly "refractory period." In most cases of gout the clinical features of the gout and the pattern of gouty arthritis are so characteristic that provocative tests are unnecessary. It

other cases, however, an effective provocative test would be useful (1) to convince the physician himself that gout was actually present in doubtful cases and (2) to convince a doubting, uncooperative patient that he actually had gout. I doubt if Dr. Lockie could maintain this high percentage of positive provocations if he applied the test to early, mild cases, that is, to those cases in which we especially need an effective diagnostic test. I have studied the effect of this "provocative diet" in several cases of classic gout but I obtained a positive test in a much smaller percentage of cases. Dr. Lockie noted frequent relief after a high carbohydrate diet had been used for two days. Did the patients obtain relief because carbohydrate was given or simply because fats were reduced? In other words, do carbohydrates have a positive beneficial effect? High carbohydrate diets will apparently reduce the concentration of uric acid in the blood of gouty patients with normal renal function but not in cases of renal insufficiency. The study of Drs. Lockie and Hubbard provides further evidence that uric acid has little or nothing to do with the cause of acute gouty arthritis even though its deposits may well be the sole or main cause of the later chronic gouty arthritis. Cholesterol is present in tophi and is increased in the blood in some cases of gout. It would seem to be important to study the comparative concentrations of fat in the blood and tissue in cases in which the results of provocative tests are positive and negative. Perhaps some by-product of abnormal fat metabolism is more important than that of purine metabolism. Just as juvenile diabetes is generally more severe than adult diabetes, so patients with juvenile gout generally fare far worse in a given number of years than do those patients whose gout begins in middle life. Juvenile gout exhibits a greater factor of hereditary gout, more rapid progression and more severe manifestations of gout and often terminates fatally in the fourth decade of life. It should also be noted that some of the induced attacks were febrile and some were not; some involved great toes, others did not but were polyarticular. Contrary to the views of many physicians, gouty arthritis does not express itself only as a red, painful great toe.

DR. WALTER BAUER, Boston: The data presented suggest that the administration of a high fat diet to patients with gout would in most instances be followed by an attack of gouty arthritis. How should we interpret these data? One patient may give a history of having had one attack of gouty arthritis each year for five years, followed by a free period of ten years, yet subsequently fall ill with attacks of gouty arthritis every three to six months. A second patient may suffer from chronic gouty arthritis beginning with his first attack. These variations in clinical course make it extremely difficult to evaluate a provocative test such as the one proposed this morning, because we cannot speak with certainty concerning the exact course of the disease or predict when a given patient is due to have an attack of gouty arthritis. Daily variations of the serum uric acid are encountered in gouty patients even when kept on a constant metabolic regimen. In some instances the variations have been as great as 5 mg. per hundred cubic centimeters. In certain cases fairly regularly recurring cyclic changes in the serum uric acid are observed. In some the serum uric acid may fall prior to an attack of arthritis; in others it may rise or remain unaffected. The same type of alterations of uric acid excretion may precede an attack of gouty arthritis. I believe that many of the experiments reported this morning were done too soon after the last attack of gouty arthritis. In some cases the provocative test may have been tried before the previous attack had subsided completely. If such was the case, it makes it extremely difficult to interpret the results. We need a provocative test for gouty arthritis which will always induce an attack of gouty arthritis in the individual with gout irrespective of when the last attack occurred. Furthermore, it would be more convincing if the proposed provocative test induced such an attack in two or three days and did not require from ten to fourteen days before doing so. The reductions of the serum uric acid of certain patients following the administration of a high carbohydrate diet are not significant. They may represent natural fluctuations. As Dr. Hubbard has pointed out, the administration of a high carbohydrate diet may or may not affect the serum uric acid level. Even if the serum uric acid remained at a lower level, one has no assurance that the patient will be protected against future attacks. I believe the

results would be of more significance if carried out repeatedly on the same individuals. The patients of choice are those without tophi, whose first attack of arthritis came early in the fifth decade and whose attacks have been recurring about every eighteen months. If the provocative test induces attacks regularly in this type of individual, it would appear to be of diagnostic use.

DR. EPHRAIM GOLDFAIN, Oklahoma City: In the treatment of some few cases that I have had in the last few years I have found that regulation of the daily dietary intake is of great importance. The diet consists of about 2,000 calories in twenty-four hours, having a ketogenic-antiketogenic ratio of one to two. The foods are so arranged that there will be a preponderance of alkaline mineral ash. The foods listed are such as will contain as large an amount of vitamins as is possible. Important food items in such daily dietary are three slices of whole wheat bread, two eggs, at least two green vegetables and two cooked vegetables, two fresh raw fruits and a pint of milk. After a certain period of time has elapsed, if it is found necessary to increase the caloric value of their diet this is done. The ketogenic-antiketogenic ratio is maintained as set forth.

DR. CURRIER McEWEN, New York: I have followed the work of Drs. Lockie and Hubbard and have tried similar studies in a few cases. In each case the period of study was divided into four periods: (1) one week in the ward on an ordinary diet, (2) two weeks on a high fat diet—the fat content being up to 298 Gm. a day, (3) one week on a high carbohydrate-low fat diet and (4) two weeks on a high purine diet. In one case this regimen was followed by another week of high carbohydrate-low fat and another two weeks of high fat-low carbohydrate diet. There were five patients studied who I believed had gout. Three of the patients on the regimen just mentioned developed definite arthritis during the period on the high fat diet, which subsided during the period on the high carbohydrate diet and then returned promptly when the high purine feedings were started. Two of the patients thought to have gout did not experience exacerbations. Two patients with hypertensive heart disease and two normal medical students, who were included as controls, all had a rise in blood uric acid on the high fat and high purine diets but had no joint symptoms. Two patients with perfectly typical and rather advanced rheumatoid arthritis developed a rise in the blood uric acid similar to that shown by the normal persons. In addition, both patients had exacerbations of joint pain, one during the high fat and the other during high purine feedings. Probably these exacerbations were purely coincidental. The patient who was the most instructive was a hospital orderly who was under observation for three years. He was the one who had the extra two periods of high carbohydrate and high fat diets. He developed pain during both periods of high fat diet but more severe attacks during both periods of high purine feeding. One of the striking things about the reactions to the diets of this patient was the complete dissociation between blood uric acid level and his joint symptoms. One time there would be pain with blood uric acid of 5 mg. and several weeks later the level would be 10 mg. or above for more than a week before pain would appear. As far as its value as a therapeutic test is concerned, I question the usefulness of the high fat diet, first because it is too unpleasant for the patient to take over the period of ten or more days which may be necessary and second because it does not seem to be always effective.

DR. L. MAXWELL LOCKIE, Buffalo: It is our hope that in the future we shall be able to study the earlier and milder cases in an effort to learn more from a metabolic point of view. The question of a refractory period following attacks is another phase which must be investigated.

Foreign Body Arthritis

DR. J. ALBERT KEY, St. Louis: Chronic arthritis developed in five cases as a result of foreign material entering the joint from the outside and remaining in the joint over a variable period. In two of the instances the condition was complicated by a low grade infection.

The first of these was a thorn, the point of which was broken off in the knee joint of a 10 year old girl and remained seven weeks. A subacute arthritis developed and arthrotomy with

hemisynovectomy, which included the tissue surrounding the tip of the thorn, resulted in an apparently normal knee.

In the second case a bullet entered the knee joint and remained embedded in the lateral condyle of the femur approximately three months. This was also mildly infected. Forty-five years later the man had a marked arthritis in this knee with degeneration of the cartilage and limitation of movement.

In the third case a needle remained embedded in the fat pad of the knee for twenty-five years. In this joint extreme hypertrophic arthritis developed. Marked improvement resulted from removal of the needle and the semilunar cartilage and thickened fat pad.

In the fourth case a piece of glass entered the calf of the leg fourteen years previous to operation and had wandered down to become lodged in the posterior portion of the ankle joint. A degenerative arthritis in the ankle was not relieved by removal of the glass and an ankylosis of the ankle was necessary.

In the fifth case a lead bullet was embedded in the articular surface of the head of the astragalus four years before operation. The x-ray examination showed infiltration of the synovial lining with lead and at the operation there was marked degeneration of cartilage in the vicinity of the bullet. Removal of the diseased bone and of much of the hyperplastic synovial lining resulted in only partial relief.

It is to be noted that if a foreign body is permitted to remain in the joint, or even embedded in the synovial tissue near the joint surface, a progressive degenerative arthritis may be expected to develop.

DISCUSSION

DR. JOHN P. STUMP, New York: Many patients with embedded foreign bodies have been advised to ignore them, because it was felt that they were stationary, encapsulated and unimportant. Dr. Key seemed to imply that he felt the first tissue of the joint to respond to foreign body irritation was the synovial membrane. This is in keeping with the knowledge of response of joint structures to any irritation. In the pathologic description of the material removed from several of his patients, Dr. Key emphasizes the proliferation of the normal villous formation of the synovial membrane. When irritated the synovial membrane will proliferate and the normal villi become elongated, thickened and fibrotic. This is true in a number of conditions. On examination of joints, especially the knees, these fibrotic villi can be felt moving in and out of the joint space. They should be properly recognized and not considered loose cartilage or joint mice. It is of primary importance that the crepitation of villous synovitis should not be considered as due to osteo-arthritis. Of outstanding significance in Dr. Key's presentation is the fact that he has shown localized irritation in, or adjacent to, a joint can initiate an inflammatory process which will extend to involve all the articular structures and result in the destruction of the joint. He furthermore indicates that with the removal of the irritant there is disposition on the part of the joint structures to return to normal. There seems to be a similarity between the way the joints Dr. Key described reacted to local foreign body irritants and the manner in which joints react to static strain. Faulty body mechanics causes strain on ligamentous supports of joints, and the close relation of the supporting structures to the synovial membrane causes an irritation of that membrane resulting in a true synovitis. Once this synovitis starts it advances and in its proliferation—especially villous proliferation—acts as an additional irritant to the joint and leads to an inflammatory reaction, which will end in a destruction of the joint. Here again, if the institution of normal body mechanics removes the irritant early enough, the joints will return to normal.

DR. ROBERT B. OSGOOD, Boston: It seems rather clear that the causes for irritation which Dr. Key finds must be either that of a low grade infection or because of the acutely irritative nature of the foreign body. If this is so, we have got to revise many of the ideas that are now taking ground, basing indication for operation on the fact that the foreign bodies represent causes of irritation. You may be familiar with the report of Dr. Smith-Petersen on the use of vitalium molds. On examining patients months or years after putting in molds, he found a smooth surface over the bone, a fibrocartilage approaching hyaline cartilage in structure. So far these metal molds have not

caused any irritation, as the material in the foreign body is non-irritative in nature itself. One would think that the synovial membrane of the joint would become irritated, and perhaps it will. Perhaps Dr. Key's paper suggests that experimenters with some of these interesting foreign materials inside the joint may yet revise their methods, and perhaps Dr. Key may have to revise his idea of the irritative nature of a foreign body inside the joint. I well remember my first experience with a foreign body in a joint. A man came in with a stiff, painful knee. The only history I could get was that once when he was a foreman he had crashed through a window. I took a roentgenogram and found eight pieces of what I took to be glass inside the knee joint. I said they should be removed. It was in a neighboring town and I felt obliged to go down and take out the pieces of glass. We found there was no knee joint at all, working for an hour and finding nothing but evidences of synovial membrane degeneration and fibrosis. At the end of an hour and a half I sewed up the joint without having found one single piece of glass.

DR. JOSEPH FREIBERG, Cincinnati: I should like to ask Dr. Key whether there is any essential difference between the reaction of the knee joint to foreign bodies, such as a needle or a piece of glass, and the smooth round body which we see occurring frequently in the knee joint apparently spontaneously, with osteochondritis dissecans and other conditions. It is my experience that the reaction of the joint is exactly similar, occurring possibly more gradually and over a longer period of time. I should like to know whether Dr. Key feels there is any particular difference in this type of resistance.

DR. M. N. SMITH-PETERSEN, Boston: The foreign bodies referred to in Dr. Key's paper are not inert; consequently they brought about foreign body reaction with excess scar formation which secondarily interfered with the mechanics of the joint. If, on the other hand, an inert foreign body is present which allows normal joint function, not only is there absence of traumatic arthritis but the process of repair will be such that normal joint structures will be the result. This has been my experience in patients on whom an arthroplasty of the hip by means of a vitalium mold has been performed. The vitalium mold is a huge foreign body but it is inert and therefore causes no foreign body reaction. Furthermore, since it allows physiologic function, the process of repair results in the creation of joint surfaces approaching the normal hyaline cartilage.

DR. WALTER BAUER, Boston: I should like to add a few words concerning Dr. Smith-Petersen's arthroplasty. In doing this particular operative procedure he denudes the head of the femur of all traces of the articular cartilage. When he finishes, the entire underlying subchondral bone is exposed. Subsequently proliferation of the fibrous tissue of the subchondral bone spaces takes place. This proliferating fibrous tissue later becomes fibrocartilage and occasionally has the appearance of an imperfect type of hyaline cartilage. Taking place, as it does, underneath a close-fitting vitalium cup, the end result is a perfectly smooth acetabular head covered with the type of cartilage described.

DR. J. ALBERT KEY, St. Louis: In answer to Dr. Freiberg's question, the result of irritation by foreign body is similar to that caused by joint mice, except that in my relatively limited experience the degeneration caused by a foreign body progresses more rapidly and progresses considerably farther than does that produced by a loose piece of bone or cartilage in the joint. Strange as it may seem, I did not think of Dr. Smith-Petersen's vitalium cup arthroplasty in connection with this paper. I think I should have done so. I have always felt when I did an arthroplasty that I was not expecting to get a normal joint. I was hoping to get something that would work without pain. I think the results he has shown me from his arthroplasty are better than anything I have ever obtained or have seen any one else obtain. The important thing about these cases is that the cartilage of the joint is destroyed and it does not regenerate. The reaction of the synovial membrane to a mild irritation is a proliferative reaction. The reaction of cartilage is a degenerative reaction. Once extensive degeneration occurs in the cartilage, the joint is gone. Consequently, foreign bodies in or near joints should be removed.

(To be continued)

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1929 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

An Interesting Case of Ascariasis. A. Bassler, New York.—p. 338.

New Parasiticide for Giardiasis.—Morrison and Swalm discuss the efficacy of atabrine in the treatment of giardiasis. They present the results obtained in ten carefully and intensively studied cases, although they used the drug in many more cases. They administered approximately the same average dose as is employed in malaria, $1\frac{1}{2}$ grains (0.1 Gm.) three times daily taken orally for five days. Then an interval of one week elapsed before a similar dose was again administered, if necessary. In this way any possibility of a toxic reaction was avoided, although toxic symptoms were not encountered. The treatment is thus simple and comparatively inexpensive. Atabrine was a completely successful parasiticide in nine of the ten cases. Eradication of the parasite caused complete abolition of symptoms in some cases, moderate improvement in others and no improvement in certain others. This observation may also represent the pathogenicity of the parasite in each instance, and it may not. However, despite the absence of "control" studies, atabrine is definitely helpful clinically in some of the cases. In those cases in which the giardia is a secondary invader, symptoms persist as long as the fundamental cause persists, despite the eradication of the parasites. The authors of articles in the foreign literature are unanimous in not finding any recurrences up to two years following the use of atabrine. This has been the experience of the present authors with their patients.

Familial Polycythemia.—Nadler and Cohn report the occurrence of four cases of polycythemia in one family. Eleven members of a family of thirteen (two siblings were not available for examination) were studied. The mother stated that of her eleven children only four had "red faces" from the time of birth. None of the children had any significant disease in their past histories. There was no evidence of factors which might initiate a secondary polycythemia—physical examination, x-ray studies and spectroscopic examination of the blood failed to reveal congenital heart disease, extensive pulmonary lesions or the presence of abnormal blood pigments. The environmental factors were similar for all members of the family. All four children had a ruddy complexion and the only physical abnormality observed was the presence of Little's disease in one case. The bleeding time, coagulation time, clot retraction, platelet count and icteric index were within normal limits in all cases. Spectroscopic examination failed to reveal the presence of abnormal pigments. There was no significant alteration in the erythrocyte count, hemoglobin content, hematocrit, mean corpuscular volume, mean corpuscular hemoglobin or mean corpuscular hemoglobin concentration of seven other members of the family. In contrast to this there were rather marked changes in the blood pictures of the four patients. These four children had erythrocyte counts ranging from 7.48 to 8.8 million per cubic millimeter, and hemoglobins ranging from 21 to 24.3 Gm. per hundred cubic centimeters of blood. The hematocrits are approximately 150 per cent of normal. The mean corpuscular volumes, mean corpuscular hemoglobins and mean corpuscular hemoglobin concentrations were within normal limits. In contrast to the common finding of leukocytosis with preponderance of neutrophils in polycythemia vera, these cases showed normal or subnormal leukocyte counts with no abnormality of the differential pattern. Similar blood pictures are found in the majority of cases of familial polycythemia. Since cases of familial polycythemia seem to differ from classic cases of polycythemia vera in that elevated metabolic rate, neutrophilic leukocytosis, splenomegaly and symptoms referable to this disease are not a striking feature of familial polycythemia, the authors assume that familial polycythemia is not the same as polycythemia vera. However, in

their cases of polycythemia the erythrocyte mass was of the magnitude of that found in polycythemia vera. Since Haden finds an increase in cell mass to be characteristic of polycythemia vera, it now seems justifiable to include "familial polycythemia" in the group of cases of polycythemia vera.

Toxicity and Systemic Actions of Congo Red.—Richardson and Dillon add to the present meager and incomplete pharmacologic data on the toxicity and general actions of congo red. They discuss the toxicity, fatal doses, cause of death and muscular actions in different animals. They find that in more than 60 per cent of the animals (rats, cats, rabbits and pigeons) the intravenous fatal dose of congo red varies from about 150 to 250 mg. per kilogram of body weight. The toxic symptoms are characterized by general depression and collapse. The dye is less toxic in dextrose than in saline solutions. The cause of death from congo red is circulatory collapse as a result of direct cardiac depression. Cardiac muscles of the perfused turtle heart and frog ventricle and excised rabbit auricle are generally directly stimulated by congo red, as indicated by an increase in tone and stoppage of the heart in systole; the frog ventricle shows variations in reaction. Congo red stimulates directly the smooth muscles in the isolated bladder, pregnant and nonpregnant uterus and intestine by a direct action on the smooth muscle. Reactions of these organs to autonomic drugs are not changed by the dye.

Excretion of Sulfanilamide in Breast Milk.—In an effort to determine whether prolonged use of sulfanilamide would result in an accumulation of the drug in breast milk sufficient to be detrimental to the nursing baby, Hac and her associates gave from 2 to 5 Gm. of sulfanilamide to twenty-five normal lactating women. The drug was administered in six doses daily for a period of three days during the first nine days of the postpartum period. The free and acetylsulfanilamide levels were determined in the blood, milk and urine. The level of the drug in the milk was considerably higher than that in the blood. The drug was still being excreted in the milk in measurable, but negligible, amounts forty-eight hours after its administration had been discontinued. The percentage of the sulfanilamide excreted in the conjugated acetyl form was relatively low the first day the drug was administered, increased slightly the second and third days, and rose sharply the fourth and fifth days when administration of the drug had been discontinued. The percentage varied from 35.1 to 83.9. The same general course was observed in blood and urine. After a fairly constant blood level had been established, the drug seemed to be excreted in the milk at a definite concentration per cubic centimeter rather than per total volume. The total amount of sulfanilamide excreted in the milk over a period of five days was never greater than 0.23 Gm., 1.6 per cent of the total dose ingested. The amount of the drug

excreted in the milk was so small that there probably would be little danger to the nursing infant unless it was unusually susceptible to sulfanilamide.

Treatment of Gonococcal Vaginitis.—Jacoby and his co-workers treated 108 women who had gonococcal vaginitis with amniotin in capsules containing 1,000 international units of estrogen inserted into the vagina every night. Ninety-two patients were apparently cured. The average time required for cure was 150 days. Relapse occurred in twenty-four patients, on the average in about 109 days. Sixty-eight patients were seemingly cured permanently. Sixteen patients were unaffected and had persistently positive smears throughout the treatment. The vaginal acidity showed great variations in relation to positive smears. The uncertainty of the ultimate results with this treatment indicate the necessity for prolonged follow-up in those apparently cured. The necessity of more intensive efforts to determine when cure is established is obvious.

Inhibition of Lactation.—Cacciarelli used aqueous whole ovarian extract in twenty-five women and anterior pituitary ovarian solution in seventy-five women in whom it was necessary to stop lactation. In the anterior pituitary-ovarian treated group the results were good in seventy, fair in three and ineffective in two. In the ovarian treated group, good results were obtained in seventeen and fair in five; no effect was observed in three cases. It seemed that in the ovarian treated cases the fullness of the breasts was a little more marked. In the anterior pituitary-ovarian patients it was not necessary to give analgesic drugs to stop pain, none of these patients required help in turning because of engorged breasts, the breasts were not as hard and as tense as they were under the old regimen of ice bags and the like, fever was entirely absent, and additional support of the breasts was not necessary. The breasts became full in two women but the freedom from pain was remarkable.

- Tuberculin Test for Adults.**—Hunt correlates the local reactions to the intracutaneous injections of different dilutions of commercial old tuberculin with the x-ray observations in the chests of 460 healthy young adults and forty-five with active lesions. His object is to evaluate the cutaneous reactions in terms of past or present tuberculous infection in the lungs. With 1:1,000, 1:5,000 and 1:10,000 dilutions there was not sufficient correlation between the cutaneous reactions and the x-ray observations worth evaluating. With the 1:100,000 dilution, however, 96.7 per cent of 230 young adults whose roentgenograms were negative gave a negative reaction and 3.3 per cent a positive reaction. With the same dilution.

forty-one of forty-three young adults who had x-ray and other evidence of active tuberculosis gave a positive reaction and two gave a negative reaction. None of the positive reactions in those with active lesions had an area of induration measuring less than 10 by 10 mm. The author considers induration the most important criterion of a positive reaction; erythema alone is unreliable. The quantitative intracutaneous tuberculin test is a valuable aid when used in conjunction with other available data and its accuracy, when properly performed and interpreted, is comparable to that of the commonly accepted immunologic and serologic diagnostic procedures.

Leukocyte Counts.—Osgood and his associates tabulate the results of leukocyte counts and sedimentation rates of healthy men and women from 19 to 30 years of age. As an examination of these tables discloses that there is no significant difference with age or sex within this group, he summarizes the results for the entire group. The figures do not include the extreme range but one that will include about plus or minus three probable errors, or 95 per cent of healthy persons. In other words, if a result in a person of this age group falls outside this range there is less than one chance in twenty that it is normal for that person. These 95 per cent ranges are, per cubic millimeter, leukocytes from 4,000 to 11,000, neutrophil lobocytes from 1,500 to 7,500, neutrophil rhabdocytes from 0 to 200, eosinophil lobocytes from 0 to 400, basophil lobocytes from 0 to 200, lymphocytes from 1,000 to 4,500, monocytes from 0 to 800, disintegrated cells from 0 to 600 and the sedimentation rate in fifteen minutes from 0.5 to 5 and in forty-five minutes from 1 to 30.

Plastic Surgery, 1938. R. H. Ivy and H. A. Miller, Philadelphia.—p. 99.

Otitic Infections.—Maybaum and Druss point out that it is advisable that the misnomer *Streptococcus mucosus* be abandoned and the correct term, *Pneumococcus* type III, be universally adopted. Realizing the importance of the pneumococcus type III infection to otology and the relative scarcity of references to this subject, they reviewed all the cases of pneumococcus type III mastoiditis observed in the otologic service at the Mount Sinai Hospital during the nine years 1929 to 1937. These totaled seventy-three. The clinical course, pathologic changes, diagnosis, treatment and outcome of the cases is presented. Bacteriologic study is of paramount importance, especially in those cases which clinically resemble streptococcal otitis. Extensive destruction throughout the temporal bone is a characteristic observation made at operation or microscopic examination. These changes are frequently encountered in spite of a latent innocuous clinical course. Intracranial complications are associated more commonly with otitic infections due to this organism than with those due to the streptococcus. They usually occur late in the disease and only occasionally in the early stages. Early paracentesis should be done when infection with pneumococcus type III is suspected, to establish a diagnosis, and autogenous vaccine should be used when the organism is identified. All the diseased bony structure should be completely exenterated. Postoperative evidence of petrositis frequently demands early operative intervention combined with the administration of sulfapyridine and serum. There is no specific therapy for pneumococcus type III meningitis. Prolonged observation of the patient after complete healing of the mastoid is of extreme importance.

Villous Synovitis.—Irish and Stump emphasize the fact that improper distribution of body weight is generally recognized as a cause of painful synovitis of the knee but, like many common conditions, is repeatedly overlooked. In their experience this type of chronic synovitis is a frequent cause of pain and disability. Only brief references to synovitis of the knees due to faulty weight bearing are found in the literature. Mechanical strain causes hypertrophy of the villous formation of the synovial membrane. In patients with weak and distorted feet the weight bearing line is thrown from its center, bringing about abnormal stress on the joint capsule, the muscular supports and the cruciate and particularly the internal lateral ligaments. The close relationship of the cruciate and internal lateral ligaments to the synovial membrane causes that membrane to be constantly irritated by the repeated trauma produced by the strain of weight bearing. This irritation sets up an inflammatory process resulting in hypertrophy of the membrane with proliferation of the villous formation. X-ray examination of the knees often shows no change from the normal, but frequently there is thickening of the soft tissues and haziness of the joint space, the latter suggesting increased density of the synovial membrane. If changes in the osseous structures exist, they are of the hypertrophic or osteo-arthritis type. With hypertrophic changes it is essential to evaluate the probability of osteo-arthritis causing the symptoms and not to consider the patient as having uncomplicated villous synovitis. The authors have long since ceased to operate on this type of knee. Villous synovitis is seen in all body types and at all ages. The definite characteristics are pain, disability, thickening of the knees, articular crepitation, improper distribution of body weight, insufficient osseous x-ray changes to account for the symptoms, and, most striking, return of the knees to normal when the body weight is properly distributed and abnormal mechanical stress and strain are eliminated. The symptoms are insidious and progress over a period of months or years. Not infrequently the patient is conscious of instability and states that the "knees give way" when unguarded walking is attempted, especially after a rest period. Questioning usually elicits other symptoms of foot strain. When the diagnosis of villous synovitis is established, the first consideration is to overcome the strain on the supports of the medial sides of the knees. As these joints are inflamed and painful, the correction must be accomplished by passive treatment, which generally requires the use of foot plates and correct shoes to force the weight away from the inner side of the joints. Constitutional factors are given full consideration. Obesity is corrected. Foci of infection and intestinal stasis are treated. In young persons and mild cases exercise is instituted to increase muscle development and tone. In older persons and advanced cases the motion of the joints required by exercise increases the discomfort. The most characteristic result of treatment after the faulty posture is corrected is subsidence of the subjective symptoms and return of the joints to normal before sufficient time has elapsed for the patient to reduce his weight or have his foci of infection removed. Physical therapy, deep heat, should be used early, as it gives relief of pain and influences the inflamed tissues to return to normal.

 Observation and Experiment, Examination and Test, Their Definition and Role in Medicine. W. D. Inlow, Shelbyville.—p. 378.

Rabies in Indiana.—Ratcliffe states that, from 1926 to June 1938, 11,478 animal heads were examined in the state laboratory; of these 6,172 contained Negri bodies. He also points out that 7,659 patients received free antirabic vaccine. Rabies was reported as the cause of death in forty human cases during the period under investigation. Wounds were known to have been present in thirty-four cases and wounds presumably in four. Local treatment is stated to have been given in fifteen cases. This low figure seems to be partially explained by the fact that in many instances the persons wounded failed to consult a physician. This, however, does not account for the fact that of the fifteen patients receiving local treatment only two were treated with nitric acid. Only twelve of the forty patients who died are reported to have received the Pasteur treatment. Of these one received the first Pasteur treatment on the nineteenth day after exposure, died the same day and probably should not be regarded as having been treated. The average number of days lost in the other cases before Pasteur treatment was given was five (variation zero to nineteen). Necropsies were performed in sixteen cases and Negri bodies were demonstrated in fourteen of them. The shortest observed incubation period in a proved case was eighteen days. In some of the unproved cases the incubation periods were still shorter. In the untreated proved cases with the wound above the clavicle the average incubation period was 22.5 days as compared with an average of 39.7 days when the wound was below the clavicle. The average duration of the disease was 4.66 days with no significant difference between the treated and untreated cases. There is need for still further education of the public to the danger of bites from sick or stray animals and the necessity of early prophylactic care at the hands of a physician who is well informed in its application.

Electro-Encephalogram of Epilepsy.—Löwenbach made electro-encephalograms of all the relatives of two epileptic patients (two of three siblings) who could be reached easily. His aim was to examine as many members of the same family unit as possible rather than a large general group of relatives of epileptic persons. He was more interested in obtaining a view into the principal facts than in aiming at statistical conclusions. Of the thirty-seven persons without any clinical sign indicating an epileptic disorder, seventeen showed an abnormal electro-encephalogram pattern, i. e., waves which, during rest, were generally irregular, slow and of high and uneven amplitude and which after a few minutes of overventilation showed an increase in amplitude to exceed 200 microvolts and a decrease in frequency to three or four per second. The large slow waves persisted in long runs for a considerable time after the period of hyperpnea. Three of the individuals exhibited outright three per second spike-and-wave groups regarded as pathognomonic of petit mal; one person had spike-and-wave groups of a higher frequency. The question is discussed whether the abnormal features are a symptom of epilepsy which is still not severe enough to take the form of convulsions or whether it is the expression of an inherited functional instability of the central nervous system and, as such, nonspecific. From the observation of a pair of identical twins, one epileptic and one normal, the two having the same type of electro-encephalograms, the author believes that the latter is the case and that some other unknown factors have to be present besides the cerebral dysrhythmia in order to justify the clinical "epilepsy."

Effect of Banana Diet on Growth.—Roberts and her associates supplemented the diet of 123 boys from 8 to 16 years of age in an institution with from two to three bananas daily over the period of the school year and they compared the effect on growth and other aspects of physical status with that of a control group consisting of 154 boys. More than 48,000 bananas were consumed during the period of observation, nine months. The bananas were well liked by the boys and were eaten with the same relish at the end as at the beginning of the study. On every basis of comparison the experimental boys had some advantage over the controls: 1. They made a slightly greater mean gain in weight (0.9 pound) and height (0.15 inch) than the controls; a larger percentage of them equaled or exceeded the gains "expected" during the period and their mean percentage gain during the year was significantly greater. 2. In ossification of the bones of the wrist they also showed slightly greater progress. 3. The Fransen measurements showed a similar trend. The boys who had received the supplement made greater mean gains in measurements of arm girth, subcutaneous tissue and weight, and also in the scores for these items. The percentage of experimental boys "selected" as undernourished by these scores, moreover, decreased to a greater extent during the period than did that of the control group. The differences do not in most cases attain statistical significance, but since they were made on matched groups and are consistent in direction they lend support to the belief that the differences are real ones attributable to the supplement in diet.

Banana Diet, Capillary Resistance and Ascorbic Acid.—Roberts and her associates also determined the capillary resistance and the ascorbic acid in the blood plasma of the boys in the banana diet study. The experimental boys averaged 0.2 mg. of ascorbic acid per hundred cubic centimeters of plasma higher than the control boys; this difference is six times its probable error and therefore significant. These results indicate that the allowances for the various dietary essentials for the boys studied should approach the higher rather than the minimal standards which have heretofore been proposed, in particular for vitamin C.

Comparative Study in Skin Sterilization.—Bass compared the antiseptic properties of pyridyl mercuric chloride and propyl mercuric chloride with other surgical preoperative disinfectants in common use. Propyl mercuric chloride and mercresin appeared equally effective and at the same time superior to all other compounds studied. Pyridyl mercuric chloride and phenyl mercuric nitrate were somewhat less effective. The largest number of compounds, and those which are most widely employed as preoperative skin disinfectants, fall into a third group which includes iodine, merthiolate, metaphen, mercury bichloride and mercurochrome. Of these, mercurochrome was the least effective. The 7 per cent tincture of iodine gave no evidence of superiority over the 3.5 per cent tincture, and it is quite possible that even weaker concentrations would give equally good results. Of eleven compounds tested, picric acid and mercuric oxycyanide were the least effective. The latter compound showed no advantage over the standard of comparison, 70 per cent ethyl alcohol.

Excretion of Sulfanilamide.—Carryer and Ivy find that sulfanilamide is excreted in the bile, pancreatic juice, gastric juice, succus entericus and saliva of the dog in appreciable quantities. Bacteriostatic levels (from 8 to 12 mg.) may be attained in the hepatic bile. Sulfanilamide appears in the bile with blood levels as low as 1.3 mg. per hundred cubic centimeters. The drug was not definitely toxic to the liver in daily doses of from 0.66 to 1.3 Gm. orally for three days in dogs weighing from 7 to 12 Kg. (15 to 26 pounds). The trend is toward decreased cholic acid and increased pigment output. The concentration of sulfanilamide in pancreatic juice roughly parallels that in the blood but is less than that of the blood. Excretion of sulfanilamide by the pancreas occurs with blood levels as low as 2.1 mg. per hundred cubic centimeters. The highest concentration of sulfanilamide occurred in the gastric juice. The concentration may be as high as 50 mg. per hundred cubic centimeters of gastric juice from four to six hours after the oral administration of 2 Gm. of the drug. Sulfanilamide was found in gastric juice with blood levels as low as 2.2 mg. per hundred cubic centimeters.

Chronic Pulmonary Moniliasis.—Beatty reports the history of a case of chronic pulmonary mycotic infection due to *Monilia albicans*. Since the patient lived in Missouri, where sporotrichosis occurs, worked in New Albany sandblasting and gave a history of a blood stream infection which followed hunting, all this was considered in the differential diagnosis. However, the most likely diagnosis was moniliasis. The most prominent symptom is dyspnea on exertion, and probably the next most prominent symptom is frequent hemoptysis. Cough is absent except during a cold. The sputum is serous; the physical changes are sparse compared with the x-ray observations. The x-ray lesion is in both apexes and the most usual location of monilia is in the bases. The patient improved under supportive treatment and iodides. He has been ill six years and, judging the future by the past, he may have several years of comfortable living if he continues to follow his treatment. Because of the marked pulmonary involvement the patient was put to bed as a tuberculous patient would be. He was treated with a streptothrix vaccine for two months, potassium iodide to the point of intolerance, vitamins and iron. He gradually increased in weight and well being. A series of roentgenograms showed a gradual but rather marked change over a period of time. There was much clearing of the inflammatory process. He had a few hemorrhages and temporary setbacks during the course of treatment but these always followed some break in his rest. The diagnosis of pulmonary moniliasis first rests on having the condition in mind. Since it may simulate other conditions of the chest, finding the organism in the sputum is the most valuable criterion for a diagnosis; however, even then secondary invasion of the lungs or bronchi or a primary fungous infection must be eliminated.

Knee Injuries in Athletics.—Of a group of 259 major injuries of the knee treated at Springfield College from 1924 to 1937, Hopkins and Huston were able to obtain the end results in 193. This group is unique in that the college trains students to be physical directors of Young Men's Christian Associations, schools and colleges. Accordingly, almost all the subjects reported continued in much more strenuous activity than is generally undertaken by the average college graduate. There was a minimum requirement of one hour of athletic work a day, but the average exceeded eight hours a week. After graduation most of the men coached these sports and frequently took an active part in them. Of the nineteen cases of simple synovitis, 89 per cent and of the fifty-nine with a lateral ligament sprain 81 per cent showed good final results. All were able to continue active athletics. The results of twenty-four semilunar cartilage injuries treated by immobilization (46 per cent good) are sufficiently better than the forty treated merely by bandaging, rest and crutches and given physical therapy (36 per cent good) to warrant the use of a plaster cast as soon as a diagnosis can be made. The results of conservative treatment were so satisfactory, nearly half being good, that the authors believe it should be tried in nearly all cases before operation is resorted to. Of the men who still have disabling symptoms the majority can be cured (66 per cent good results) and all have been sufficiently improved by operation to engage in active athletics. There were twenty-two cases in which there was a questionable injury of the semilunar cartilage; the result was perfect in eight, good in seven and fair in seven. There were twenty-nine patients who underwent operation for the removal of injured menisci. The results were perfect in ten, good in nine and fair in ten. No individual complained of limitation of motion and in the patients examined there was no significant limitation.

Amenorrhea and Sterility.—Kaplan reestablished menstruation in 124 of 142 amenorrheic women. All the women received roentgen therapy to the pelvis; 104 were given additional therapy to the pituitary and in six the thyroid also was treated. The amenorrhea in these women has persisted for from one month to fourteen years and sterility from one to eighteen years. The oldest patient was 45 and the youngest 19 years of age. The data show that, the younger the patient, the more successful the results. Those most successfully treated were within the 21 to 29 year group. There were fifty-two subsequent instances of pregnancy. Of the fifty-two who conceived, seventeen did so more than once. Five women aborted; two of these aborted twice. Forty-four went to term and delivered fifty normal babies, one woman was pregnant, in one woman an ectopic pregnancy developed which was terminated by operation, and one bore an abnormal child. In the group of living children there were twenty-seven boys and twenty-three girls, and reports from their parents have disclosed no abnormalities or physical deformities. Because of the success achieved with irradiation the author reiterates his previous conclusion that irradiation, when properly employed, is not harmful to the mother or to the offspring and that it has proved a valuable therapeutic procedure for the treatment of amenorrhea and the relief of sterility.

Intelligence of Syphilitic Children.—Perlman and Gardiner determined the intelligence quotient of fifty congenitally syphilitic children from the outpatient department of the Children's Hospital. Forty-three children were Negro and seven white. The Children's Hospital is located in an area heavily populated with Negroes. The average intelligence quotient for the group was 90.3, classifiable as "average" in intelligence. This average is below the theoretically "perfect" average of

100 which is expected in an unselected group of white children. However, this was not an unselected group, as all the children were drawn from the lowest socio-economic groups. Median ability below the average is to be expected in such a group. In fact, the intelligence quotient of 90.3, which was the average for this group, is probably little if any below what would be "expected." Pintner has stated that the Negro intelligence quotient is below that of the white; it ranges from 83 to 99, with a central tendency around 90. Approximately four years (as an average) had elapsed from the time of birth of the subject until the time when a diagnosis of syphilis was made by means of the blood Wassermann and Kahn reactions. This fact is of importance, as it is frequently claimed that the longer the disease runs untreated, the greater damage it does and the less amenable it is to therapy. While this claim is probably true with regard to visceral syphilis, it probably is not true with regard to its effects on mentality, which apparently fail to develop to the degree that might be expected. In this respect the observations differ from those of von Kiss and Rajka. The results of antisyphilitic therapy in the series were successful. Treatment consisted of the routine use of standard antisyphilitic remedies. The minimal treatment received was for a period of at least one year. The maximal number of years of treatment was ten, with appropriate rest intervals between courses of therapy. The Wassermann and Kahn reactions were completely reversed in thirty-two children and partly reversed in eight. In only six instances was the blood Wassermann fast. Unfortunately, two other children received insufficient treatment, while the parents of two other children refused to have their children treated.

*Similarity of Australian Q Fever and Disease Caused by an Infectious Agent Isolated from Ticks in Montana. R. E. Dyer.—p. 1229.

Q Fever and Infectious Disease from Ticks.—Dyer presents evidence which indicates that an infectious agent isolated from ticks in Montana is similar to that of Q fever. He summarizes the similar and dissimilar points of the two infections: 1. Q fever has been recognized principally in persons associated with animals, which suggests infection from direct contact with infected animal tissues or with animal parasites. The epidemiology of the Montana infection is unknown, but the presence of the virus in ticks suggests that human infections may be found in rural areas. 2. The one recognized human infection with the Montana virus was very similar to the published descriptions of the Australian Q fever cases. 3. The only point of difference in susceptibility of animals to the two infections is the failure of the American workers to find the monkey susceptible, in contrast to the success in infecting this animal in Australia. 4. Neither disease has been found to produce agglutinins for Proteus X strains. 5. The clinical pictures in guinea pigs, as described in the literature, are similar, with the exception that the Montana infection has been reported to produce a definite local cutaneous reaction following subcutaneous inoculation, while the Australian workers state that no particular local reaction follows such inoculation. In the author's laboratory the Q fever strain produced general reactions in guinea pigs which, although similar to those produced by the Montana virus, were milder. This may be explained by the attenuation of the Q virus during transit to this country. Rickettsiae have not been observed in guinea pigs with Q fever, while they are present in abundance in guinea pigs infected with the Montana virus. 6. Cross immunity tests are identical, with the exception that epidemic typhus and, to a lesser extent, endemic typhus apparently produce more immunity to Q fever than to the Montana virus. 7. In one well controlled test the serum from one recovered case of the Montana infection gave results identical with that from a recovered case of Q fever when tested with a suspension of Rickettsia burneti prepared in Australia. 8. As far as protection tests have been tried, no immunologic difference has been observed between the virus of Q fever and that isolated from Montana ticks.

Life Insurance Risks of Malaria.—Faust inquired of three groups of life insurance companies (including eight major organizations doing business in the South and five other companies with negligible Southern business) and finds that in the group of standard insurance risks malaria does not constitute a particular hazard, even though the death rate from malaria in this insured group has been found by one company to be more than eight times as great as in the whole registration area. Some companies do not employ special safeguards, others refuse to write standard policies in certain areas in the South, and still others require an extra premium for persons living in malarious areas or with a history of malaria who are otherwise good risks. The population in the South more commonly affected by malaria belongs to a poorer economic group and the safeguards which the representative life insurance companies set up to prevent excessive loss in substandard groups indicate clearly that they recognize the dangers of the disease in the lower economic strata of the population.

Effect of Sinus Disease on the Eye.—Since there is a paucity of case reports showing an unmistakable connection between sinus operations and the clearing up of ocular disease, Cullom presents six cases which left no doubt in his mind that sinus disease was the cause of the pathologic condition in the eye. Operation on the sinuses cleared up the visual condition. Four cases resembled toxic amblyopias. The patients suffered from marked disturbance of vision. The gradual onset and the progressive failure of useful vision indicated ultimate permanent blindness. In one case there was an inflammatory condition of the vitreous which had been present over a long period. In one case there was clear evidence of pressure on the optic nerve from an unresolved empyema of the sphenoid sinus. In this case vision might have been restored by spontaneous rupture. The great improvement in the general health of these patients is gratifying. They exhibited marked symptoms of toxemia with pallor, loss of weight, strength, appetite and vitality. Five patients had rheumatism. They all regained their color, weight and vigor and were relieved of their rheumatism. While these cases are rare, the author believes that they are more numerous than the few reports indicate. He is of the opinion that every patient with failing vision of obscure origin should receive the benefit of a careful examination of the sinuses, including roentgenograms.

Sulfanilamide in Compound Fractures.—Because of the bactericidal and bacteriostatic properties of sulfanilamide and as in vitro studies show these properties to be augmented greatly in concentrations higher than could safely be obtained by systemic administration, Jensen and his associates, after complete débridement of compound fractures or dislocations, place from 5 to 15 Gm. of crystalline sulfanilamide in the wound before closure. These wounds are closed tightly by interrupted sutures of silk to the skin only. Closure without tension on the wound is accomplished when necessary by longitudinal splitting of the skin away from the site of the wound but parallel to the closure. Complete reduction is obtained at the time of débridement and absolute immobilization is accomplished by immediate application of unpadded plaster splints held in place by either circular bandage or plaster. Reduction is maintained by continuance, when necessary, of skeletal traction in conjunction with the plaster splints. Casts are not windowed and the wound is left untouched until such time as consolidation of the fracture allows replacement of splints by circular casts prior to ambulatory treatment. The minimum of 000 plain catgut suture material to accomplish hemostasis is buried in these wounds; no attempt is made to suture any deep structures except nerves. To date, the authors have treated thirty-nine compound fractures and two compound dislocations by this method. In two cases, both tibias, one eight days and the other twelve days after reduction, the fractures were recompound and subsequently became infected. The other thirty-seven healed by primary intention without local or systemic evidence of wound infection. The authors conclude that the local use of sulfanilamide has opened the way for more effective treatment of contaminated wounds. The amount to be used in each specific wound depends on the extent of trauma and contamination, but 20 Gm. is the advisable upper limit in any adult patient. From 5 to 15 Gm. has been found sufficient for average to severe wounds.

Paroxysmal Tachycardia.—Campbell and Elliott made a study of the 100 unselected cases of paroxysmal tachycardia that they saw from 1925 to 1932. In forty-two the diagnosis was confirmed by the electrocardiograph, in thirty by observation of an attack and in twenty-eight by the history alone. Of the forty-two attacks with graphic records, eight were ventricular and thirty-four supraventricular. Ventricular paroxysms were uncommon without serious heart disease. There were forty-one cases of heart disease; nineteen rheumatic, two syphilitic, eight hyperplastic and twelve myocardial. There was no heart disease other than the arrhythmia in fifty-nine, though there was a goiter in four of these. The rate was between 140 and 240 in 90 per cent of the cases. Paroxysms were generally of short duration, lasting hours rather than days, and in twenty-eight twelve hours or less. There were sixty-one the customary duration was less than two hours, and in another twenty-eight twelve hours or less. There were six in which it was about twenty-four hours; in only seven it longer than this and in eighteen there were attacks lasting more than one day. Long attacks included an undue portion of the ventricular paroxysms and were more common in cases of myocardial disease. Paroxysmal tachycardia symptom rather than a disease. In a minority of cases it accompanies serious heart disease, when, of course, the prognosis is grave. Ventricular paroxysms form a fairly large proportion of this group and are rare otherwise. In most cases paroxysmal tachycardia is not in itself of any primary significance. It is due to reflex causes more often than to any grave change in the cardiac muscle. There is no close association between paroxysmal tachycardia and paroxysmal auricular fibrillation. The prognosis of paroxysmal tachycardia as regards life is excellent unless it is of the rare ventricular type and appears relatively late in life as the first indication of disease of the coronary arteries or unless before the paroxysms have started there is already serious heart disease. Three of the authors' patients lived fifty years after the onset of their paroxysms, another eighteen for more than twenty years and another twenty-six for more than ten years, and most of them are still in good health. There is no constant tendency for the paroxysms to get worse as life advances, and usually some form of treatment can be found which will reduce the frequency and the discomfort produced by the attacks.

Fatality Following Antisyphilitic Treatment. P. C. P. Ingram.—p. 268.

Desensitization for Cutaneous Menstrual Allergies.—Géber used serum obtained from the patient at the culmination of cutaneous menstrual disorders in the treatment and prophylaxis of these eruptions. Together with these alterations of the skin, general symptoms usually develop: severe, unassuageable headache, nausea, dizziness, lumbago, neuritis, heavy cramps localized to the lower part of the abdomen and pains in the extremities and joints. There is no constant correlation, however, between the intensity of the general and the cutaneous symptoms. The author states that he has demonstrated experimentally that these menstrual disorders are all due to a substance which appears in the organism at menstruation and to

which the patient is supersensitive. If he took blood from a patient suffering from menstrual urticaria when the symptoms were culminating he was able to cause urticaria of short duration by reinjecting the serum intravenously. He was not successful, however, in isolating the substance responsible for the allergic conditions. Subsequent experiments showed that the contents of a herpes vesicle produced a herpes eruption if given to the same patient in the menstrual interval. But whereas the menstrual eruption for twenty years always attacked the left buttock, the vesicles produced experimentally appeared on the right buttock. After this artificial eruption had subsided, the woman remained free from menstrual herpes for a year (as long as she was under observation). Thus experimental herpes established in the intermenstruum exerted a desensitizing action. He supposes that the substance that causes the symptoms is present in maximal quantity in the blood stream simultaneously with the acme of the symptoms. Serum taken at this time seems to contain enough specific antigen to accomplish full desensitization. Desensitization could never be accomplished by the next series of injections usually brought about full desensitization. Desensitization of another patient, even if she had the same symptoms; thus the antigen proved to be highly specific. Desensitization remained adequate for years in some cases; in others, relapses occurred from two months to one year after treatment. Desensitization proved useful in a few cases of bronchial asthma; the attacks were relieved and did not recur for a long time. Three patients with trigeminal neuralgia, previously treated in vain by various procedures, have been free of symptoms for a long time.

Diffused Skeletal Metastasis in Mammary Cancer.—Lamarque discusses the alleviation of pain and the general improvement that occur when skeletal metastasis from cancer of the breast is irradiated locally. He states that even if some metastases prove resistant to the rays the immediate results are good. The general condition of the patient is improved by roentgen therapy: pains diminish or disappear, often evolution may be slowed or stopped for a time, recalcification may be obtained. But further new lesions always appear, the evolution of which nevertheless remains slower than before. Although the diffuse skeletal metastasis in cancer of the breast is not to be cured, it is possible to obtain some definite improvement by roentgen treatment. Every patient of this group must be systematically submitted to roentgen therapy. That this method of treatment does not alter this problem. For the present action of radiation is based either on direct or on secondary logical when the clinical results are considered, as it is difficult to understand how doses too small to kill cancerous cells in a tumor are able to kill them in metastatic locations.

Radiosensitivity of Malignant Melanomas.—Ellis used radium and roentgen therapy in the treatment of thirty-eight cases of malignant melanoma. In twelve of these the therapy was definitely successful in dealing with the lesion treated, in two the success is doubtful, in thirteen the evidence is indefinite, and four were not treated either because the disease was too

advanced or because treatment was refused. The malignant melanoma in the twelve definitely successful cases was situated in the vagina, limbus of the eye, lobe of the ear, upper alveolus, skin near the left ear, right cheek (recurrence), axillary gland metastasis, forearm, vulva, right cheek, glands in the groin and left cheek. This, the author believes, shows that some malignant melanomas are definitely radiosensitive. On the other hand, others have not responded equally well to irradiation, but the causes for the failure might well be something not inherent in the melanoma itself. The factor of general resistance, although it may be important in any individual case, is not, he thinks, of any greater importance than in the case of carcinoma of the lip. Yet no one with any authority suggests that carcinoma of the lip is insensitive to irradiation. The general resistance factor, which is the patient's own "treatment" for any tumor, is probably the most important of all. That there is such a quality is undoubted, but it cannot be accurately defined or estimated, and so its effect in any one case cannot be gaged and thus it does not materially affect this argument. The local resistance, however, is a factor which can be estimated and should be taken into account.

Agglutination Test for Weil's Disease.—Brown and Broom firmly believe that until some method of standardizing cultures of *Leptospira* is employed the serologic diagnosis of Weil's disease should be undertaken only in laboratories in which the idiosyncrasies of the antigens are well known. Although in principle the agglutination test for Weil's disease is essentially similar to a bacterial agglutination test, difficulties have been encountered which would mask or invalidate the results in the hands of an inexperienced observer. The authors have some reason to believe that cultures which have been quite recently formalized are not agglutinated to so high a titer as those formalized for forty-eight hours or more. From time to time a macroscopic agglutination technic has been advocated, and there is no doubt that when a suitable antigen can be obtained a florid serum will give a positive result after one hour's incubation. The macroscopic method is not nearly as sensitive as the microscopic, and the authors are of the opinion that certain serums of low titer, such as those shortly after the sixth day of disease, may be missed if the macroscopic test is employed.

Adrenalectomy for Paranoid Psychosis with Adrenogenital Virilism.—Allen and his collaborators describe the case of a woman 34 years of age who was suffering from hirsuties and a paranoid schizophrenic psychosis. In view of their previous observations of improvement in sexuality following unilateral adrenalectomy, they performed the operation on this patient. The immediate response to operation was a decided temporary deterioration in the patient's mental condition, but her final return to normal passed through a phase with a direct bearing on sexuality. For this reason the sterone content has been periodically examined, covering altogether a period of ten months, and it has remained below the preoperative level on the color test. The patient's clinical condition has remained satisfactory. This case shows the nature of sexuality and its relation to the functional psychoses, which often coincide with

endocrine instability—such as schizophrenia and involutional psychoses. The facts are that sexuality develops along two parallel lines—a somatic and a psychic development.

Pregnandiol Excretion in Menstrual Cycle.—Hain and Robertson correlated the excretion of pregnandiol with endometrial biopsies in five sterile women during the menstrual cycle. No pregnandiol was excreted during the proliferative phase—that is, the early part of the cycle. Pregnandiol excretion was found in all cases in which there was a secretory endometrium. Estimations of the excretion of pregnandiol will reveal, the authors hope, those cases of sterility and other abnormalities in which progesterone therapy is specifically indicated. The specimens of urine covered two consecutive days' output, and assays were made throughout two cycles in four cases and one cycle in the other case. An interval of either two or three days elapsed between the collection of specimens. In no case was pregnandiol found in the urine during the first half of the cycle. The days on which it was recovered in the urine varied from the fifteenth to the thirtieth day of the cycle in the five cases. In only one case was there any divergence between the endometrial biopsy and excretion observations; on the twenty-fourth day a pregnandiol output of 10.5 mg. was associated with an endometrial picture which is not secretory.

Gonadotropic Substance for Whooping Cough.—On the ground that whooping cough is a disease that shows a preference for attacking children less than 10 years of age, and old persons occasionally, and that adults are invariably immune to it, Venkatachalam and Ratnagiriswaran considered it probable that the power to resist and overcome the disease might be closely associated with the activity of the sex glands, the dominant feature of adult life. Based on this assumption, they used a charcoal adsorbate of the gonadotropic substance of pregnancy urine (orally or parenterally) in the treatment of 136 children. Satisfactory results were obtained in 80.3 per cent of the cases. The most severe symptoms (whooping, vomiting and coughing) were alleviated in about one week. The drug was also found to be effective as a prophylactic, in that it conferred an immunity.

Vitamin C in Pulmonary Tuberculosis.—Bakhsh and Rabbani determined the vitamin C content of the urine of twenty-four tuberculous patients who did not improve on other methods of treatment (bed rest, artificial pneumothorax and the like). Nineteen of these patients had a deficient urinary content of the vitamin. Twenty patients were given daily from 150 to 200 mg. of vitamin C in tablet form by mouth over a period of six weeks. In addition every patient received 500 mg.

of the vitamin daily by intramuscular injection for four days during the first week of treatment. Three patients left the hospital of their own accord during the early part of the treatment, as their condition deteriorated greatly. The appetite of two of the remaining patients was favorably affected. An increase in weight from 1 to 21 pounds (0.5 to 9.5 Kg.) occurred in ten cases. The weight in two cases remained stationary and was less in five. The cough, as reported by the patients, was lessened in eight, in one it was increased and in the remaining eight it was uninfluenced. Expectoration, however, was increased in only three cases in which the cough was diminished. An increase in the total erythrocyte counts ranging from 100,000 to 3,000,000 cells per cubic millimeter occurred in thirteen patients. The rise in hemoglobin, however, did not parallel the increase in the erythrocytes. This favorable effect on the rate was appreciably reduced. In eleven cases the sedimentation rate was parallel with the improvement in cough in most instances but it had no relationship to the changes in the erythrocyte counts. Of the three patients with past histories of hemoptysis it developed again in two during the course of vitamin C treatment. In both patients vitamin C injections failed to control the hemorrhage, one of the patients left the hospital of her own accord and the other responded to artificial pneumothorax. No appreciable anatomic changes were observed in the lungs, as judged by x-ray and clinical examination.

Cod Liver Oil Enemas for Ulcerative Colitis.—Gainsborough used cod liver oil retention enemas in the treatment of six patients with ulcerative colitis. The patients were given a high-calory low-residue diet. Retention enemas were given morphine, if necessary, had reduced the diarrhea and intestinal irritability to a degree that made the retention of the oil possible. The early injections of oil were given during the day; but, when the patient could retain oil for several hours, the injections were given in the evening and were often retained through the night. The initial dose was 2 ounces (60 cc.) and this was increased by 2 ounces at a time to a maximum of 8 ounces (240 cc.) in accordance with the patient's capacity of retention and comfort. When an opaque enema and x-ray study showed that the colon was involved up to the splenic flexure or the transverse colon, the bed was tilted up from the foot for about an hour after the enema was given. The first three patients, in whom the duration of the illness had been six, three and eighteen months respectively, have now been apparently quite well and free from symptoms for six months. The fourth patient, with a twelve year history of colitis, remained well for fifteen months and then stated, in answer to inquiry, that she had relapsed. The fifth patient, with a six year history, remained well but not entirely free from symptoms for fifteen months and then was readmitted for a relapse but since having further treatment has been symptom free for six months. The last patient, with a history of colitis for eighteen months, showed some improvement after treatment; but, since hemorrhage persisted, an ileostomy was performed and the patient died later. The method is by no means curative but shortens the illness in some cases and reduces pain; cod liver oil, compared with other local applications, is tolerated better. The author believes that it is advantageous to continue the treatment two or three times a week for a few months after remission has been established. The patient can be instructed in self administration.

Sulfanilamide for Typhoid.—In the autumn of 1938 the admission of six patients suffering from typhoid provided Harries and his co-workers an opportunity for the therapeutic trial of prontosil (sulfanilamide) and sulfapyridine in the disease. Another patient admitted in 1939 was treated with a

combination of sulfapyridine and Felix's Vi serum. With one exception (the last patient) the six cases of typhoid arose as the result of a localized epidemic from a single source. All the patients were adults and were admitted when the disease was well established. The presence of rose spots in every instance indicated that the disease had passed the first week. The attacks were not mild; toxemia ranged from severe to very severe. All the patients recovered. Of the seven patients, five had constipation throughout the attack. Sulfanilamide appeared to be better tolerated than sulfapyridine; the latter, as is well recognized in other conditions, tends to cause nausea and vomiting which, in typhoid especially, are an obvious drawback. The new soluble sodium salt of sulfapyridine may overcome this disadvantage. There is insufficient evidence to draw any conclusions as to the relative therapeutic superiority of the two preparations, but the authors believe that there can be little doubt that sulfanilamide can exercise a bacteriostatic effect on *Bacillus typhosus* in the blood stream. A typical relapse in second case, with its commencing step ladder rise of temperature, was unquestionably aborted by sulfapyridine given on the first day of the relapse, but also a blood culture, positive on morning of the fifth day after administration of the drug, can be confirmed by others that the sulfanilamide drugs consistently inhibit *Bacillus typhosus* in the blood, one of the major problems in the therapy of typhoid is on the way to solution. It is suggested that by the inhibition of bacteremia, these drugs on bacteremia, that after their administration further crops of rose spots, beyond those present on admission, either did not appear or were sparse. There is evidence that positive urine cultures are used (two cases), but the authors state that the data are insufficient to enable them to express any opinion about the feces. The most striking result in their series was obtained in the last case from a combination of sulfapyridine and a single intramuscular injection of Felix's serum. The patient entered the stage of convalescence within ten days of admission, although, as a precaution, the drug was continued for a further week. As in other infections for which both chemotherapy and specific serotherapy are available, the authors believe that the most promising treatment of typhoid is likely to be a combination of sulfanilamide and Felix's Vi serum.

Acute Rheumatic Polyarthritides.—Van der Merwe discusses the differences in the symptomatology of acute rheumatic fever in childhood and in adult life, stressing its insidious onset and the fact that cardiac symptoms can appear before

arthritic changes appear. He recommends large doses of sodium salicylate over a period of at least six weeks. Sodium salicylate is considered a specific antirheumatic drug in opposition to the tendency to assume that rest and symptomatic treatment are equally efficient. It is suggested that rheumatic carditis, which at first offers no hope for the future, can subside to such an extent that the patients become self supporting and relatively normal individuals again. The resulting tachycardia alone is no indication for unlimited rest but should also be treated with digitalis and careful mobilization. Recommending such invalids to the seaside before proper treatment is carried out is scientifically unsound.

Endotoxoid and Specific Serum for Tuberculosis.—

Grasset states that it has been found that when tuberculosis endotoxoid (obtained from the tubercle bacillus by an extraction process of repeated freezing at a low temperature and submitted to the detoxicating action of formaldehyde) is injected in doses increasing from 0.05 to 1.5 cc., over a period of several months, it exerts a definite therapeutic action in tuberculous patients. The therapeutic action manifests itself in a variety of tuberculous conditions by a general action which is antitoxic, progressive and durable. There is a fall in temperature and pulse and an increase in weight; toxic phenomena disappear and the general condition of the patient improves. There is a regression of the infection at the site of the lesions, followed by a fibrotic cicatrization and regeneration of the parenchymatous tissue as far as it is physiologically possible. The action is more limited and more delayed in advanced cases. No contraindications have been observed. The results obtained in 242 cases of tuberculosis with tuberculous endotoxoid, either alone or in conjunction with specific serum treatment, are discussed. There were 220 cases of pleuropulmonary infection; 63 per cent of the Europeans with this infection derived benefit from the treatment. A somewhat lower percentage of the natives were benefited, an occurrence which may be attributed to their higher susceptibility to tuberculous infection. Also patients with laryngeal, urogenital, peritoneal, intestinal, glandular, ocular and osseous tuberculosis were benefited.

Quinine Treatment of Trachoma.—Chang used 10 per cent quinine bisulfate in the treatment of eighty trachomatous patients; twenty were completely cured, twenty-seven almost completely cured, twenty-four showed considerable improvement and nine had no improvement. In general the follicles disappeared earlier than the papillary hypertrophy. On the average the effect of the treatment (by local application) became manifest about two months after the treatment had started. The disease was improved or even cured if the treatment was carried on regularly for six months. A few patients were found to be resistant to quinine, but they responded favorably to alternations of quinine with copper. In a number of cases quinine treatment was found to be definitely more effective than the copper stick, as in them the trachoma was not influenced by the latter but cured by the former. The author believes that, until a more specific therapy for trachoma is discovered, quinine treatment may be considered as the relatively quickest method to cure trachoma.

Polynuritis Following Treatment with Uliron (Sulfanilamide Preparation). Mme. Radermecker.—p. 349.

Accidents in Metrazol Therapy of Schizophrenia.—

Gross and Gross-May differentiate three groups of complications from insulin and metrazol therapy of schizophrenia. They first cite those of a mechanical nature which involve the osseous, tendinous and muscular systems. They show that these complications are explained by the mechanism of the epileptic crisis and the enormous muscular tension which it provokes. The second group of accidents are those involving the vascular system. In this connection the authors cite cases of arrhythmia, irregularities of the pulse, syncope and so on. They themselves observed auricular fibrillation which persisted for four hours. The third group of complications are the pulmonary ones. The authors cite cases of respiratory arrest, pulmonary embolism and pulmonary abscess and say that, according to Ligerink, these accidents can be explained in three different ways: (1) by a thrombophlebitis resulting from intravenous injections (this seems the most probable course) and followed by embolism, (2) by vascular spasms due to the specific action of metrazol and (3) by aspiration during the attack. Further they give a detailed history of a patient in whom they observed severe respiratory disturbances in the course of combined insulin and metrazol therapy. In the conclusion they say that their enthusiasm for the new treatments for schizophrenia is impaired neither by reports of accidents nor by statistics on fatalities occurring in these treatments. Of 2,000 schizophrenic patients, half of whom had been treated with insulin, Malzberg found the mortality to be four times greater in the subjects who had not been treated than in those who had been treated. The authors conclude that they are justified in not letting the risk of death deter them from continuing the metrazol therapy of schizophrenia.

*Value of Testosterone Therapy in Metrorrhagias and Menopausal Disorders. Desmarest and Capitain.—p. 1031.

Disappearance of Hypophysial Diabetes in Fever Attacks. A. Salmon.—p. 1033.

Testosterone in Metrorrhagias and Menopause.—Desmarest and Capitain report the significant results achieved by means of testosterone in the therapy of metrorrhagias, singling out five of their numerous cases for clinical comment. These selected patients were divided into two groups: three young women between 17 and 30 years of age with menstrual and intermenstrual hemorrhages due to a uterine trauma and two women of 50 suffering from menopausal bleeding. The therapy, suggested by unexpected favorable secondary results in the treatment of mastopathies, consisted in medication with 10 mg. of testosterone at varying intervals of time and in decreasing amounts, as determined by the needs, and was not employed until after careful examinations for possible local or general pathogenic conditions. Testosterone therapy, successful as a hemorrhastatic agent, had a remarkable additional effect on the lipodystrophy and ovarian cyst of one of the patients in the first group but did not arrest disorders of the sympathetic nervous system in cases of menopause. In postmenopausal disorders the authors say that they successfully employed a combination of estrogen and testosterone discriminatingly administered in small graduated doses with time spacing, after an investigation in each case of existing dysfunction in ovarian and hypophysial activity. The authors recommend the simplicity and effectiveness of the combined therapies in stabilizing menopausal and postmenopausal stress and strain.

A Ten Year Experiment with BCG Vaccination in Norrbotten. C. Naeslund.—p. 710.

Humoral Syndrome of Lipoid Nephrosis.—Dalous, Valdigué, Fabre and Pons present a joint clinical diagnosis, supported in detail by blood, chemical and urine analyses, of two nephropathic patients observed over a period of time. Case 1 is diagnosed as nephritis with an initial stage of a purely nephrotic syndrome, case 2 as a purely lipoid nephrosis. The absence of edemas in both cases, in spite of a significant plasmic hypoproteinemia, induced the authors to reject thyroid therapy in favor of a lipoid-deficient high nitrogen regimen with opotherapy. Complete and definite results were obtained in one case. In the other, treatments were suspended when the symptoms of nephritis replaced the nephrosis syndrome. The authors stress the need of supplementing anatomic with physiopathologic criteria in nephropathic patients who recover but show important modifications. Nephropathies in tuberculous persons may appear as syndromes of lipoid nephrosis revealable only by clinical and humoral tests and having no connection with renal amyloidosis. The characteristic syndrome may be cured and leave no trace or evolve along with amyloidosis and nephritis or be complicated by them. Chrysotherapy was effective in disclosing the clinical and humoral disturbances against the background of tuberculosis.

- Present Status of Cerebral Surgery. G. J. Vlavianos.—p. 145.
*Roentgen Therapy of Traumatic Epilepsy. W. von Wieser.—p. 171.

Roentgen Therapy of Traumatic Epilepsy.—Von Wieser shows that traumatic epilepsy reacts to treatment with roentgen rays in the same manner as do the inflammatory and genuine forms, provided the cerebrum is irradiated by the direct method. If an attempt is made to treat epilepsy by the indirect method, it is necessary to differentiate between irritations of the sympathetic alone and of the medulla oblongata plus the sympathetic. The first of these two indirect methods of roentgen therapy can be used neither in traumatic or inflammatory nor in old cases of genuine epilepsy, whereas the second one can be used in all types of epilepsy, but, since experiences with the latter method are rather limited as yet, it is not known whether it will produce as satisfactory permanent results as does the direct method of roentgen treatment. Regarding the mode of action of the direct and indirect methods of roentgen therapy of traumatic epilepsy, the author says that the direct method tries to influence the cause of the disease whereas the indirect method aims to reduce the threshold for the stimuli that elicit the attacks.

Metabolism of Oxalic Acid in Surgery on Kidney. M. Fernandez.—p. 166.
*Pneumopyelography in Urinary Calculosis. G. Bravetta.—p. 188.

Pneumopyelography in Urinary Calculosis.—Bravetta discusses the diagnostic value of pneumopyelography in calculosis of the urinary tract. He uses oxygen, which is injected into the kidney pelvis by means of a sterile common piston syringe in doses of from 7 to 15 cc. (unless there is dilatation of the pelvis, in which case a larger amount of oxygen is injected). The existence of a sufficient renal equilibrium is necessary in making pneumopyelography. The procedure is carried out without the administration of any preoperative anesthesia. The patients are kept on a light diet during the previous day. An enema is given just before making pneumopyelography and then a ureteral catheter is introduced up to the pelvis and the retained urine allowed to flow out slowly. Oxygen is injected slowly to prevent sudden pressure. When

the patient reports a local feeling of fullness no more oxygen is injected, and without removal of the injecting syringe the roentgenogram is taken. Compression of the abdomen is exerted while the roentgenogram is being taken to prevent interference of intestinal gases with the pneumopyelographic image. The author has obtained satisfactory diagnostic results in many cases, five of which are reported. According to him, pneumopyelography is of value in the diagnosis of calculi of the urinary tract. The procedure has proper indications, namely the diagnosis of radiotransparent calculi of common tract and the verification of the exact location of common urinary calculi, for the selection of the proper operation. It is advisable to resort to the procedure when the clinical symptoms are those of calculi of the urinary tract and the x-ray examination of the tract and pyelography fail to show the calculi (probable presence of radiotransparent calculi). It is also advisable to resort to it when urinary calculi have been shown by roentgenography or pyelography and one wants to ascertain their exact location. The author calls attention to the fact that acute or chronic uremia, fever and hematuria are contraindications to the procedure.

- Antalgic Power of Histamine. I. Brignolo and G. Dominici.—p. 629.
*Action of Vitamin E on Healing of Experimental Wounds on Parenchymatous Organs. E. Bartolomucci.—p. 644.

Action of Vitamin E on Wounds.—Bartolomucci studied the action of vitamin E, administered by mouth, on the healing of experimental wounds of the liver and spleen. He experimented on rabbits and rats which were placed in three different groups as they were fed with a diet rich in vitamin E, a normal diet and a diet which was lacking in vitamin E, after having been wounded. Animals in each group were killed for observation and microscopic study ten, twenty, thirty, forty and fifty days from the beginning of the experiment. The author found that vitamin E administered by mouth accelerates healing of wounds of parenchymatous organs, whereas the lack of the vitamin retards the healing process. The retardation is obvious in comparison to that which takes place in the organs of animals on a diet rich in vitamin E and also in comparison to that which takes place in the organs of animals on a normal diet.

- Prognosis of Metasyphilis (Cerebral Antigens) in Diagnosis and Alterations of Cholesterolemia in Epilepsy. E. Dossi.—p. 207.
G. Gomitato.—p. 319.

Cerebral Antigens in Metasyphilis.—Dossi discusses the value of the reaction of deviation of the complement in which cerebral substances are used as antigens for the diagnosis and prognosis of metasyphilis. He performed the reaction in the cerebrospinal fluid of 307 patients who were suffering from syphilis (with or without involvement of the central nervous system), nonsyphilitic diseases and metasyphilis. He used cerebral antigens or else an antigen of ox heart. The cerebral antigens were prepared with the brain cortex of a cadaver of a paralytic patient or else with that of the cadaver of a patient who had no syphilis. The cerebrospinal fluid was examined in the active and inactive stages. The amount of complement which was used was half of that which is used in the Wassermann reaction. The reaction with the cerebral antigens gave constantly negative results in the cerebrospinal fluid of patients who were suffering from nonsyphilitic diseases as well as in syphilis without involvement of the central nervous system. It gave negative results in two cases of dementia paralytica, before treatment in which the reaction with the antigen of ox heart was slightly positive. In the five cases of cerebral syphilis, three of tabes and ninety-five of dementia paralytica in which the reaction was positive for both the cerebral and the ox heart antigen, the positivity of the reaction was less intense for the cerebral antigen than for the ox heart antigen. In fifty-four paralytic patients (twenty-five who improved after the treatment and could be dismissed and

twenty-nine who became worse) the reaction was repeated by the end of the treatment with the following results: It continued to give positive results for both the cerebral and the ox heart antigen in sixteen paralytic patients who improved from the treatment as well as in sixteen who became worse. It became negative for the cerebral antigens and remained positive for the ox heart antigen in seven paralytic patients who improved after the treatment and in eight who became worse. It became negative for both the cerebral and the ox heart antigen in two paralytic patients who improved and in five who became worse. The evolution of paralysis in the eight cases that gave a negative reaction with the cerebral antigen before treatment was rapidly fatal in one case; five patients became worse and two improved so that they could be dismissed in time. The reaction gave negative results for the cerebral and ox heart antigens in the cerebrospinal fluid of four patients who were suffering from dementia paralytica and had had treatment from 1930 on. In these cases the curves of the colloidal tests were normal. The author therefore denies the value of the test for the differential diagnosis of neurosyphilis and metasyphilis and for the prognosis of metasyphilis. He also believes that the disappearance of a positive reaction with the cerebral antigens with persistence of a positive reaction with the ox heart antigen indicates that the latter is more sensitive than the former.

Chronic Hepatosplenic Syndrome with Jaundice Treated by Ligation of Splenic Artery. G. Bombi.—p. 501.

*Intrapleural Pneumolysis in Artificial Pneumothorax. F. Speciale.—p. 510.

Pleural Adhesions.—Speciale describes the technic of intrapleural pneumolysis (Jacobaeus's operation) and discusses the main indications and contraindications of the operation. He resorted to the operation in seventy-three cases, including those of unilateral pneumothorax with either a normal contralateral lung (forty-one cases) or else contralateral tuberculosis (thirteen cases) and nineteen cases with bilateral artificial pneumothorax. The adhesions were of different types and thickness in the various cases. They caused direct traction of the parenchyma of the lung and maintained an insufficient pneumothorax in twenty-eight cases, maintained open tuberculous cavities in evolution in forty-one cases and were present in four cases of saccular pneumothorax. The operation gave satisfactory results in forty-nine cases in the group (insufflations could be continued, the sputum became negative for tubercle bacilli and the symptoms and functional disturbances were controlled). The symptoms and functional disturbances either remained unchanged (twelve cases) or had slight favorable modifications (nine cases). Postoperative empyema developed in two cases. It followed a long course to recovery of the patients from proper local treatments. Paralysis of the vocal cord with almost complete aphonia developed in one case. It disappeared spontaneously within a year from compensatory hyperfunction of the contralateral vocal cord. The author concludes that intrapleural pneumolysis is the method of selection for the treatment of pleural adhesions which prevent complete collapse in artificial pneumothorax. The danger of accidents, the development of operative and postoperative complications and the possibilities for the development of infection or for the propagation of tuberculosis are smaller than those from some other operations which are commonly resorted to. The results are satisfactory in a large number of cases. An exact preoperative diagnosis of the origin, size and characters of the adhesions and of the relations of adhesions to neighboring structures is of importance. It is done by radioscopy, x-ray examination of the thorax and pleuroscopy. The best results from the operation are those obtained from progressive section of adhesions which exert traction on restricted zones of the lung. The earlier the operation after verification of the insufficiency of the pneumothorax, the better the results. The operation is indicated in pleural adhesions with insufficient collapse, in the course of an efficient artificial pneumothorax (if the adhesions are amenable to resection) and in the course of elective pneumothorax with persistence of slight functional disturbances. A thorough mastering of the technic is of importance.

*Roentgen Treatment of Keloids. V. del Giudice.—p. 877.

Cancerigenic Cholesterol and Cellular Oscillation. G. Lakhovsky.—p. 889.

Roentgen Treatment of Keloids.—From 1930 up to the present, del Giudice has treated 300 cases of posttraumatic keloids by means of superficial roentgen irradiations (from 90 to 100 kilowatts, with an intensity of 2 milliamperes and administered through an aluminum filter of 2 or 3 mm. at a distance of 20 or 30 cm.). The dose consisted of 200 or 250 roentgens for each irradiation up to a total dose of from 850 to 1,000 roentgens for each series. Early in the treatment pruritus disappears and a transient erythema appears. In the group of patients treated by the author 281 recovered, ten improved and there were nine failures. As a rule the keloid disappears after the first treatment. However, the treatment can be repeated after an interval of two or three months if necessary. A soft flexible skin of normal color and appearance replaces the keloid after treatment. The author concludes that roentgen irradiations are the treatment of choice in posttraumatic keloids. The sooner the treatment is resorted to in the course of the development of keloids, the better the results. The appearance of symptoms of infection in a wound (either surgical or nonsurgical) is an indication for the administration of roentgen irradiation for the prevention of keloids. The preventive roentgen treatment is indicated in infection of wounds, even if they heal by first intention.

Microscopic Examination of Industrial Dusts by Means of Roentgen Rays. H. Gärtner.—p. 377.

Further Contributions to Roentgenologic Diagnosis of Pulmonary Asbestosis. E. Saupe.—p. 391.

Impairments Caused by Vanadium.—After calling attention to the fact that the use of vanadium has greatly increased in recent years, Symanski reviews the literature on the disorders supposedly caused by it. Reviewing the complicated procedure by which vanadium is produced, he shows that of the various transformation products it is only the vanadium pentoxide, particularly in the readily absorbable form of dust, which is harmful to the health of the workers. He subjected the workers who came in contact with this substance to a careful examination. He describes observations on nineteen men. He found a number of characteristic disorders. He observed conjunctivitis with inflammatory injection of the conjunctivas, suppurating discharge and corresponding complaints such as burning of the eyes, rhinitis with reddishness of the nasal mucosa and coryza with watery discharge, also a feeling of soreness in the pharynx, continuous coughing with more or less profuse expectoration, occasionally sanguineous pharyngeal secretion, a feeling of dryness in the pharynx, sensations of constriction of the chest, occasionally piercing pains, the typical aspects of a more or less severe subacute or chronic bronchitis, considerable sonorous and sibilant rales in the absence of signs indicating inflammatory infiltration of the pulmonary parenchyma, no tuberculous complications but roentgenologic signs indicating a chronic bronchitis. In view of the fact that all examined persons had been active in the production of vanadium for only a few years, the author thinks that it is necessary to consider the possibility of the development of chronic changes. Contrary to reports in the literature, he never observed resorptive gastrointestinal disturbances, renal symptoms, increased nervous sensitivity, disturbances of the central nervous system or impairment of vision. Moreover, he found no characteristic changes in the composition of the white or red blood picture, especially signs of anemia; likewise there were no indications of toxic impairment of the large visceral

glands or of the circulation. Regarding the prevention of the described disorders, he says that all the processes in which vanadic acid is liberated in the form of dust should be mechanized and encapsulated as much as possible. In the mixing rooms, suction apparatus should be installed and suitable masks should be worn by the workers. Moreover, he thinks that the workers could perhaps be rotated, so that they would have days or weeks in which they could recuperate from the effects of the contact with the vanadium.

- *Hypophysial Diabetes. H. Bartelheimer.—p. 185.

Hypophysial Diabetes.—Bartelheimer stresses the importance of recognizing in the hyperfunction of the hypophysis (anterior lobe) a diabetogenic agent. He offers a cursory particularization of the contributions of others to this subject, interspersing some case verifications of his own. Experiments, according to the author, have confirmed the role of the hypophysis in diabetes mellitus, some authors also charging it with the responsibility, along with the adrenal gland, for disturbances in the fat metabolism of diabetic patients. The clinical evidence for the known effects of the hyperfunction of the hypophysis in acromegaly, adiposogenital adenomas and Cushing's syndrome motivated the author's observations of the relative frequency of oligosymptomatic forms of Cushing's disease in diabetic persons. These forms represent all transitions from the almost complete form of Cushing's syndrome to disguised forms difficult of recognition. In these the author finds the possibility of establishing, through clinical observations, the connection between diabetes mellitus and the hypophysis and designates a series of symptoms to be studied. One of these symptoms that may secure detection of disguised forms is the frequent occurrence of cutaneous striae. Whenever these appear, the adrenal gland may be involved, as is evidenced by their artificial production in human beings through stimulation of the adrenal gland. Hyperfunction of the basophilic cells of the anterior lobe may be of supreme importance for the clinical comprehension of hypophysial diabetes because of its numerical preponderance. Of the 300 patients in the home for diabetic persons in Garz on the island of Rügen 10 per cent showed clear traits of hypophysial hyperfunction in the direction of Cushing's syndrome, less so of the acromegalic type. According to the author, metabolic behavior is more or less characteristic. Noteworthy are the relatively large supply of glycogen in hypophysial diabetes, a special tendency in some cases to acidosis and glycosuria more independent of carbohydrates than is observable in pancreatic diabetes. The author's therapy consisted in dosing patients showing hypophysial hyperfunction daily with androgens and estrogens for about a week, in observing the metabolism and in noting modifications of the glycosuria and blood sugar content. He cites the treatment of twelve women and eight men with various endocrine preparations and varying results. This short-range therapy did not admit of testing for permanent results.

Granulocytopenia and Leukemia.—Citing the various forms of leukocytosis, Voth shows that some forms are designated as leukemoid leukocytoses or as leukemoid myeloid reactions. If a patient dies during a leukemoid reaction, it may be

difficult to determine whether he has a leukemoid reaction or an acute leukemia. Cases have been reported in which a granulocytopenia has changed into a leukemia. The author reviews a number of cases from the literature and shows that they have the following factors in common: (1) the comparatively short duration (a few weeks to six months); (2) acute course of the second (the leukemic) stage; (3) fatal outcome during the second stage. The hemograms during the first stage show a moderate to severe leukopenia in the presence of neutropenia and a more or less severe anemia. The second stage is characterized by anemia and by the typical hemogram of acute myeloblastic leukemia. Similar disease entities are interpreted sometimes as granulocytopenia, sometimes as atypical granulocytopenia and sometimes as aleukemic myeloblastic leukemia. Investigations seem to indicate that in many cases it is impossible to differentiate between granulocytopenia and aleukemic leukemia. In this connection the author points out that the earlier opinion that the peripheral blood picture reflects the condition of the hematopoietic organs is no longer acceptable because it has been proved by intravital examination of the bone marrow that the central hematopoietic organs may show entirely different conditions from the peripheral blood. He shows that disturbances in the bone marrow may involve the maturation, division and elimination of cells. In the conclusion he emphasizes that it becomes increasingly more necessary to dispense with excessive classification in diseases of the blood. As the knowledge about the blood advances, it becomes evident that the blood is extremely sensitive in its reactions and that within these reactions there are many gradations and transitions. Thus it becomes understandable that a disease may be identical with one which formerly was regarded as entirely different. A granulocytopenia and an aleukemic leukemia may represent the same, that is, the first stage of a disturbance of the bone marrow, of which the acute myeloblastic leukemia may be the second stage.

- *New Simple Flocculation Reaction with Hayem's Solution. W. Gros.—p. 781.

Simple Flocculation Reaction.—According to Gros, Jakobson observed a special kind of serum protein which can be precipitated with Hayem's solution and which occurs in many cases of myeloma. Jakobson also succeeded in isolating the protein fraction that can be precipitated by Hayem's solution, and he demonstrated that it is a special kind of euglobin. Subjection of the body to various precipitation reactions disclosed that it is not identical with Bence Jones protein. Gros detected the special protein body in a woman with multiple myeloma and, since the Takata reaction was likewise strongly positive in this patient, he decided to search for the protein body that can be precipitated with Hayem's solution also in other serums giving a positive or negative Takata reaction. Studies were made on 150 specimens of serum; 100 had been obtained from healthy persons and from patients with mild, nonfebrile disorders, the other fifty from patients with atrophic cirrhosis of the liver, severe parenchymatous icterus and nonhepatic disorders, such as rheumatic polyarthritis, decompensated cardiac defects and malignant tumors. The normal serums all gave a negative Takata reaction, whereas the fifty pathologic serums gave a positive one. Regarding the procedure of the flocculation test with Hayem's solution in normal serums, the author says that he slowly titrated 1 cc. of native serum at room temperature and found that normal serum requires large quantities of Hayem's solution for precipitation in that on the average 2½ cc. is required to produce turbidity and 3.02 cc. to produce an irreversible flocculation. In the serums with positive Takata reactions, however, an entirely different behavior was observed.

Serum from patients with myeloma, for instance, already showed a noticeable white precipitate, which, however, proved reversible after the addition of only one drop (0.03 cc.) of Hayem's solution. In the further titration of the serum, every drop produced again a strong flocculation. The addition of 1 cc. produces turbidity, which after the further addition of 0.08 cc. is transformed into irreversible flocculation. In a table the author indicates the behavior of other Takata-positive serums. He emphasizes that the flocculation reaction with Hayem's solution can entirely replace the complicated Takata reaction. It has the advantage that it is much more simple and rapid than the Takata reaction and that it can be performed by the practitioner. The required quantity of reagent is a measure of a greater or lesser positivity of the reaction. The author discusses the diagnostic significance of the intensity of the flocculation reaction for various diseases.

Stilbestrols in Ovarian Insufficiency.—Tüscher thought it advisable to study the activity of the synthetic estrogenic substances not only in cases in which ovarian insufficiency was brought on by surgical removal or physiologic involution of the ovaries but also in those cases of ovarian insufficiency which appeared in comparatively young women, for instance after a pregnancy. Such women may complain of cessation or of rare or scanty menstruation, of increase in weight, of hot flashes and so on, that is, of signs that are characteristic of the physiologic menopause. Instead of employing the natural female sex hormones, it was decided to employ the stilbestrols, namely the di-ethylstilbestrol dipropionate and the di-ethylstilbestrol di-acetate. In addition to a number of women with ovarian dysfunction of unknown etiology, the author treated eight women with secondary amenorrhea or hypomenorrhea after pregnancy. After relating the clinical histories of several of these patients, he says that the exclusive administration of stilbestrol may bring on the menstrual flow and regulate the cycle. In cases in which the administration of the stilbestrol did not induce menstruation or in which the effect was only temporary, corpus luteum hormone was given. The dose of stilbestrol was not increased, in order to avoid excessive doses and undesirable effects such as vomiting. The author advises that treatment be initiated during the proliferative phase with 1 cc. (0.5 mg.) of the di-ethylstilbestrol dipropionate or with 1 cc. (0.75 mg.) of di-ethylstilbestrol di-acetate. This dose is given every second or third day for a period of two weeks. If there is no result or if the menstruation is weak, the same series of treatments can be repeated two or three times, if necessary, with the aid of the corpus luteum hormone during the second half of the intermenstrual period. As stated before, the author advises against an increase in the individual dose of stilbestrol. He concludes that the results that are obtained with the stilbestrols indicate that although they differ from the natural female sex hormones in chemical structure they nevertheless exert the same biologic action. They are well tolerated when given in correct doses.

Consumption of Vitamin C During Fever.—Falke says that in patients with febrile diseases the tolerance test always reveals a higher deficit than corresponds to the ascorbic acid content of the blood. In order to determine the quantity by which the consumption of vitamin C is increased during fever, he determined the vitamin C balance in patients who were subjected to fever therapy on account of arthritis deformans. The fever therapy was begun after it had been determined what was the relationship of intake and elimination during saturation and in the absence of fever. By determining the elimination of vitamin C during the administration of 300 mg. and by comparing the quantities in the absence and presence of fever, it was found that the consumption is about 100 mg.

higher on days on which the patient has fever than on other days. An attempt also was made to prevent a reduction of the elimination of vitamin C during fever by giving larger doses of ascorbic acid. When this was done, it was found that the increased consumption amounted to 300 mg. When this test method is used, however, a considerable disturbance is produced by the fact that the daily consumption is influenced by the quantity that is administered. In all, observations were made on fifty-eight days with fever and on seventy-two days without fever. The number of patients was fifteen.

Clinical Picture of Necrosis of Pancreas. D. Forstmann.—p. 968.

Extra-Uterine Endometriosis.—Von Mikulicz-Radecki presents a clear and concise review of the important features in the study of uterine and extra-uterine endometriosis and their interrelations. His report is based on eighty-eight cases of endometriosis, seven cases extra uterine, discovered in 2,283 patients on whom gynecologic surgery (exceptions noted) was performed during the course of seven years of clinical observation. In his analysis of the site of the disease the author includes 884 cases reported by the Mayo Clinic (Counsellor) in 1938 and 104 reported by Cattell in 1937. Of the entire number (1,076) ninety-one were cases of extra-uterine endometriosis, with recto-uterine (thirty-five) and rectosigmoid (thirty-nine) preponderating. The remaining cases (seventeen) were those of the appendix (six), bladder (four), navel (six) and on abdominal scars (one). Interweaving selected cases of his own into the discussion of the symptomatology and diagnosis of extra-uterine endometriosis, the author points out, together with other important symptoms and observations, that the presence of bluish cysts (in their origin enlarged endometrioid glands with extravasated menstrual blood) constitutes a true diagnostic criterion of the disease. He advises frequent protoscopies and exploratory excision for discriminating between endometriosis and rectal carcinoma, for which the disease has been mistaken in the past. No uniform therapy is possible in recto-uterine endometriosis. The author stresses the fact that many patients require neither surgery nor roentgen rays but merely to be kept under clinical observation. However, when these forms of treatment are resorted to, discrimination should be made, with due consideration of the age of the patients. Recto-uterine endometriosis in pregnancies is variable: proliferation may increase or decrease or remain stationary. Surgical intervention in a patient with endometriosis caused by a previous gynecologic laparotomy and in another patient with endometriosis of the ovaries was completely successful. According to the author, carcinomatous evolution of endometriosis is rare (only five authenticated cases in the literature). A uniform etiology for all forms of endometriosis is not yet recognizable. Extraperitoneal endometriosis is of sufficiently frequent occurrence to challenge attention.

Toxin Resembling Dick Toxin in Bacterial Filtrates.—Bader cites reports from the literature which indicate that there are strains of staphylococci that are capable of eliciting a cutaneous reaction, which can be inhibited by the administration of scarlet fever serum; that is, staphylococci produce a toxin which resembles Dick toxin in its effect on the human skin. The question arose whether this characteristic of staphy-

lyococci exists also in other bacteria. In order to determine this the author prepared culture filtrates from thirty-two bacterial strains that had been isolated from different disease processes. There were nine strains of *Staphylococcus albus anhaemolyticus*, eight of pneumococci of various types, five of *Bacillus pyocyaneus*, eight of *Bacillus proteus vulgaris* and two of meningococci. The author realized that testing the filtrates for the production of substances resembling Dick toxin was possible only by means of the neutralization test with scarlet fever serum, because the similarity of the majority of cutaneous reactions does not permit the drawing of conclusions from these alone. He succeeded in neutralizing the action of four culture filtrates (one *Staphylococcus albus anhaemolyticus*, one pneumococcus type I, one pneumococcus mucosus, one proteus) by means of scarlet fever antiserum, whereas the neutralization with the diphtheria serum, which was used for control purposes, did not succeed. From these results he concludes that there are a number of pathogenic micro-organisms which, irrespective of the disease process from which they are derived, produce a toxin that exerts a cutaneous action similar to the Dick toxin, although they have no connection with scarlet fever. He further decided to isolate various bacterial strains from scarlet fever patients and to subject the culture filtrates of these to the same neutralization experiment on the human skin. Of the culture filtrates of ten micro-organisms, which were obtained from the nasopharynx of seven patients with scarlet fever, eight could be neutralized. The author concludes that it must be assumed that there are a number of bacteria which produce toxins resembling Dick toxin in their cutaneous action. This characteristic is especially frequent in the micro-organisms that are obtained from scarlet fever patients.

Multiple Hereditary Disturbance of Ossification of Epiphyses.—Müller thinks that the time has come when all such terms as coxa vara adducta chondrodystrophica (Freund), atypical chondrodystrophy (Jansen), chondro-osteodystrophy (Brailsford), achondroplasia atypica (Wahren), chondrodystrophia congenita tarda (Schorr), osteochondro-arthritis (Weiss) and hereditary multiple epiphyseal disturbance (Ribbing) should be defined as a uniform type. The many reports indicate that this articular disturbance is not at all rare. Nevertheless the author thinks that its mild forms are often overlooked, for their roentgenologic aspects may easily be mistaken for the terminal stages of other articular disorders. The chief aid in the recognition and observation of the multiple hereditary defect in the ossification of the epiphyses is the x-ray examination. On the basis of a large number of his own observations and of many reports in the literature, the author discusses the clinical aspects of this entity as they become manifest on the large joints, particularly the hip, knee, shoulder and elbow. He shows that there are gradations, from the severest deformity of the entire skeletal system to mild changes on the joints, which present the aspects of an osteochondritis dissecans. He is convinced that close connections exist between hereditary multiple disturbances of the epiphyseal ossification and the multiple forms of osteochondritis dissecans; he thinks that the two represent only gradual differences or different stages of the same disorder. He regards the term "familial multiple disturbance of epiphyseal ossification" as the most suitable term and emphasizes that the hereditary or familial appearance is one of the most characteristic aspects of this disorder. The mild forms of this disorder deserve attention, because their true nature and particularly their hereditary character are frequently overlooked.

- Manner of Transmission of Syphilis to Fetus. Loe Ping Kian.—p. 1430.

Oculoglandular Syndrome and Venereal Lymphogranuloma.—Ouwejan points out that in 1889 Parinaud described an infectious conjunctivitis of animal origin which Gifford in 1898 designated as Parinaud's conjunctivitis. It is characterized by a severe conjunctivitis and by involvement of the preauricular and submandibular lymph nodes. The author shows that the term oculoglandular syndrome or conjunctivoglandular syndrome is to be preferred to Parinaud's conjunctivitis. In the course of the years it became evident that the disorder is not a disease *sui generis* but that the syndrome may occur in different diseases. The author reports three cases of Parinaud's oculoglandular syndrome in which the virus of venereal lymphogranuloma was probably the cause. To be sure, it was not possible to demonstrate the virus in the pus from the eye or in the conjunctival tissue but the Frei test was positive in two cases and venereal lymphogranuloma had previously occurred in the third. The author admits that the Frei test may produce nonspecific reactions and that the aforementioned cases may belong to this group. However, the literature reports cases in which Parinaud's oculoglandular syndrome was caused by the virus of venereal lymphogranuloma and the author thinks that this possibility exists also in the cases described here. The aim of this report is to direct attention to this possible causal connection between venereal lymphogranuloma and Parinaud's oculoglandular syndrome. The recognition of this connection is of therapeutic significance, because by means of fuadin (sodium antimony biscatechol-disulfonate of sodium) and sulfanilamide venereal lymphogranuloma can now be cured more rapidly than formerly.

- *Does Bovine Type of Tubercle Bacillus Produce an Independent Disease Entity in Human Subjects? C. J. Huët.—p. 2744.

Insulin in Treatment of Cutaneous Pruritus.—Reviewing the literature on the treatment of cutaneous pruritus, Vervloet cites among others von Noorden, who was able to counteract by means of insulin general pruritus of nondiabetic origin which had proved refractory to other treatments. Vervloet himself observed that in several patients with hepatic disease, in whom insulin produced good results, cutaneous itching disappeared largely or entirely. He reviews the clinical histories of several of these patients and says that twice 10 units or twice 15 units, to which sugar was added, was usually sufficient. He thinks that the therapeutic effects produced by insulin in several forms of cutaneous pruritus are probably due to the correction of the intracellular metabolism in the liver and the kidneys. He shows further that this medication deserves recommendation in pruritus of pregnancy and in other forms of cutaneous pruritus.

Does Bovine Tubercle Bacillus Produce a Special Disease Entity?—Huët points out that it has been said that the bovine tubercle bacillus produces less dangerous forms of tuberculosis than does the human type. On the other hand, it has been said that the bovine bacillus has an especial predisposition for certain organs, such as the lymph nodes and the bone system, and that it has an especial tendency to generalization. The author describes his observations on nineteen children in whom bovine bacilli were detected and then reviews Tobiesen's observations in twenty-six cases of bovine tuberculosis, six of which were fatal. Further he discusses the incidence of bovine infection observed by various other investigators and he reaches the conclusion that it is not probable that the bovine type of the tubercle bacillus as such is less virulent than the human type. He thinks that the route of infection is responsible for the fact that bovine tuberculosis is generally more benign than is the tuberculosis that is caused by the human type. The latter type of bacilli invade the most

vulnerable organ, the lung. In bovine infection, however, the different route of invasion leads to the involvement of other organs, which have a better prognosis for overcoming the tuberculous infection. It remains unproved that the bovine bacillus has a special tendency for metastatic forms of tuberculosis. Figures which seem to favor this assumption can be explained by the selection of the material.

Sulfanilamide in Urinary Infections.—Brandstrup and Sindbjerg-Hansen report experiences with chemotherapy in infections of the urinary tract in puerperal women. The authors observed pyelitis in about 1.5 per cent of the puerperal women and pyuria in approximately 10 per cent. Pyelol (a calcium chloride phenyl salicylate preparation) was employed by the authors for many years and in the spring of 1937 they began treatment with sulfanilamide. They compare the results which they obtained in 439 cases treated with pyelol and 120 treated with sulfanilamide. The patients who were treated with sulfanilamide were given two tablets three times a day for four days. With this dose the urine became free from bacteria in 73 per cent of the cases. In some of the remaining 27 per cent of cases the treatment with sulfanilamide was continued for another four days and in this manner the percentage of recovery was raised to 88. Treatment with pyelol made the urine free from bacteria in 51 per cent of the cases. Thus the results obtained with sulfanilamide were far superior to those obtained with pyelol. Moreover, the treatment with sulfanilamide is brief, inexpensive and convenient; it requires no restriction of the diet or of the water intake. No dangerous complications were observed by the authors, but since the literature reports cases in which undesirable secondary effects resulted from the same dosage as that employed here, it is necessary to keep the patients under observation for the duration of the treatment.

Emesis Gravidarum.—Wetterdal says that investigations on 7,000 pregnant women revealed severe emesis in 12.7 per cent, moderate emesis in 31.1 per cent and slight emesis in 22.5 per cent, the remaining 33.7 per cent being entirely free from emesis. Of the women under 20 years of age, 62.2 per cent were free from emesis. In the other age groups the distribution of cases of emesis was uniform. It was observed also that emesis occurs as frequently in primiparous as in multiparous women. The author examined the cholesterol content of the blood serum in 311 persons, fifteen of whom were not pregnant. The average value was 247.9 ± 0.33 mg. per hundred cubic centimeters. In the 206 pregnant women who had emesis the average value was 210.1 ± 0.13 mg. per hundred cubic centimeters, whereas in the ninety pregnant women in whom emesis was absent the average was 238.6 ± 0.15 mg. per hundred cubic centimeters. Thus pregnant women with emesis have a lower cholesterol content than have those without emesis and it seems that hypocholesteremia is one of the symptoms or one of the causes in many cases of emesis gravidarum. The author points out that attempts have been made to counteract the hypocholesteremia by the administration of cholesterol and various other biliary components. He decided to use a preparation with which several investigators had obtained favorable results, and fifty tablets of which contain 2.76 Gm. of glycocholic tetracetate, 4.83 Gm. of extract of ox bile, 0.23 Gm. of cerium isovalerianicum, 2.3 Gm. of sodium bicarbonate and 2.3 Gm. of calcium carbonate. A fluid preparation of similar composition is employed for intramuscular injection. The author administered the preparation mostly in the form of tablets, two tablets being given three times a day. In a number of cases in which this treatment failed to have

the desired effect the fluid preparation was administered. More than four injections were seldom given but the author gained the impression that more injections would have produced better results. Among the cases of emesis tested for cholesterol and treated with the preparation, the results are known in 104 cases. In sixty-seven, approximately two thirds of these, the treatment was successful. These sixty-seven patients had a low cholesterol content, whereas the thirty-seven in whom the treatment was a failure had a relatively high cholesterol content. This seems to prove that treatment is less effective when the cholesterol values are relatively high.

Treatment of Acute Suppurative Otitis in Scarlet Fever with Streptamide Irrigation. (Preliminary Report.) Eva Møller.—p. 1665.

Fluids for Patients with Pyloric Stenosis.—Clausen and Ringsted state that in pyloric obstruction with marked dehydration and chloropenia there is sometimes a reduction of the kidney function. Administration of a considerable amount of sodium chloride and fluid is often required for complete rehydration. It may be impossible by clinical examination alone to estimate accurately the degree of dehydration. Examination of the diuresis or serum chloride or urine chloride alone, or determination of the chloride balance, affords no certain indication of the state of hydration. It is best estimated by determination of the serum chloride concentration and the twenty-four hour urine chloride. In patients greatly undernourished and dehydrated because of long continued obstruction these determinations must be supplemented by analysis of the plasma protein before rehydration with saline solution, in order to avoid the possible development of a hypoproteinemic edema. In cases of hypoproteinemia one or more blood transfusions are advised in the preoperative treatment to raise the serum protein concentration and make rehydration possible. The authors believe that when in pyloric stenosis the obstruction is almost complete at least 100 Gm. of dextrose should also be given daily, at all events during the last two days before operation, either as a 5 per cent solution of dextrose or by the addition of 5 per cent dextrose to the salt solution. Generally speaking, isotonic dextrose solution should be given after the operation to compensate for the physiologic fluid loss, and isotonic salt solution to replace the nonphysiologic fluid losses and, if the patient was not rehydrated before operation, to continue rehydration, under control of serum and urine chloride and serum protein.

Norsk Magasin for Lægevidenskaben

- *Nosography and Diagnosis of Boeck's Sarcoid. H. J. Ustvedt.—p. 1677.

Nosography and Diagnosis of Boeck's Sarcoid.—Twelve cases with the probable diagnosis of Boeck's sarcoid are discussed. In two cases there was renal involvement as described by Salvesen (scanty albuminuria, considerably reduced function, normal blood pressure). Cutaneous changes were present in only two cases. Ustvedt stresses that pulmonary changes, especially bilateral hilus adenitis, seem to dominate the picture. Pulmonary changes appeared in eleven of his cases, bilateral hilus adenitis in nine. He says that in bilateral hilus adenitis where careful examination excludes tuberculosis, malignant granulomatosis, cancer and leukemia, Boeck's sarcoid should be borne in mind. Of the diagnostic criteria in Boeck's sarcoid (exanthem, histologic picture, tonsil biopsy, tuberculin energy, hyperproteinemia, other blood changes, cystic osteitis) none can be considered absolutely certain. Diagnosis can be made only on the complex of manifestations from skin, eyes, bones, glands and lungs, and the greater the combination of phenomena, the more certain the diagnosis. The differential diagnosis between Boeck's sarcoid and typical tuberculosis is usually the most difficult. Many cases of so-called chronic miliary tuberculosis are assumed to have depended on Boeck's sarcoid. Even if Boeck's sarcoid should prove to be a peculiar form of tuberculosis, it must be regarded as distinct from typical tuberculosis.

CONTACT DERMATITIS FROM WEEDS: PATCH TESTING WITH THEIR OLEORESINS

CHAIRMAN'S ADDRESS

BEDFORD SHELMIER, M.D.
DALLAS, TEXAS

When the term contact dermatitis of plant origin is employed, one immediately thinks of poison ivy and pictures an acute dermatitis venenata of sudden occurrence with marked swelling and vesiculation of the affected areas. This impression of plant dermatitis is due to the high incidence of acute dermatitis venenata occasioned by contact with the poison ivy vine or shrub, this plant being a violent skin irritant for a high percentage of those who touch its leaves or indirectly come in contact with some object contaminated with its sap. The few persons who are mildly sensitive to poison ivy react with only an erythematous eruption following such exposure. Occasional instances of a chronic type of dermatitis have been observed in such persons following frequently repeated contact with this plant.

Acute dermatitis occasionally follows contact with weeds, but the usual clinical picture is that of a chronic dermatitis. Sensitivity is usually moderate, and frequently repeated exposures over a long period of time result in a seasonal dermatitis persisting during the growing season of plants.

The average person with weed eczema gives a fairly characteristic history. The eruption usually begins in the spring or early summer and continues until the first killing frost or freeze. During the first few years the dermatitis is seasonal, corresponding closely to the growing season of plants. At the onset the eruption is usually erythematous, scaling and pruritic. Frequent exacerbations, caused by massive exposures, are characterized by an increase in the erythema, swelling and oozing and occasionally by fine vesiculation. With each seasonal recurrence the dermatitis becomes more widespread, owing to a gradual increase in sensitivity and the manual spread of the antigenic oleoresins to areas of the body covered by clothing. Thickening of the affected areas follows the trauma occasioned by protracted scratching and rubbing. Seasonal attacks extend further into the winter before completely healing. Sooner or later the eruption becomes perennial—extremely severe during the growing season of plants

with remissions during the winter months. Erythema, edema, oozing and crusting disappear, but pruritic, lichenified areas often persist until the new spring weeds return.

The sites affected are usually the exposed areas such as the face, neck, backs of the hands, wrists and ankles. The eruption gradually spreads to involve the forearms and legs. In men the penis and the anterior surface of the scrotum are often erythematous and thickened. Occasionally patchy areas of dermatitis appear over the trunk and groins. In the more widespread and long standing cases, those areas which are more easily irritated by external agents, such as the face, the sides and front of the neck and the flexures, become markedly lichenified.

Prolonged healing time is characteristic. If patients with weed eczema are hospitalized and contact with vegetation is absolutely avoided, disappearance of the eruption usually occurs within three to six weeks. If these patients are ambulatory but avoid actual contact with weeds, the healing time is frequently prolonged for from six weeks to several months, since they continue to come in contact with small amounts of the antigenic oleoresins through such intermediary objects as contaminated work clothes, tools, pets, udders and bellies of cows in milking and work stock.

Most of the affected persons have been farmers and farmwives, workers in oil fields and others whose occupations bring them into almost daily contact with vegetation.

THE ETIOLOGY OF WEED DERMATITIS

Each weed contains an ether soluble oleoresinous dermatitis producing fraction and a water soluble albuminous hay fever producing fraction. This can be readily demonstrated by tests on a person in whom a dermatitis develops from contact with a specific weed and hay fever or asthma from inhaling its pollen. Patch tests on this person with portions of the antigenic plant will evoke a delayed eczematous reaction. If all the dermatitis producing oleoresin is removed by repeated ether extraction, the remaining de-oiled portion of the plant will not give a positive patch reaction. A water extract of this de-oiled residue, which still contains the atopic fraction, will then evoke the typical immediate urticarial scratch or intradermal hay fever reaction.

The eczema producing oleoresins appear on the leaves, stems and flowers of many weeds as tiny globules of oil, readily seen with a hand lens. These oleoresins are very sticky and adhere tenaciously to the skin or clothing. Contact of sensitized persons directly with the plant or with contaminated intermediary objects is followed by dermatitis. Some plants, such as poison ivy, do not contain resin ducts in the epidermis of their leaves and must be bruised for a person to come in contact with their antigenic oils.

Owing to lack of space, this article has been abbreviated for publication in THE JOURNAL. The complete article appears in the author's reprints.

Read before the Section on Dermatology and Syphilology at the Ninetieth Annual Session of the American Medical Association, St. Louis, May 17, 1939.

Previous contact is necessary for the development of sensitization to a plant. Heinbecker¹ examined by patch test sixty-five Baffin Island Eskimos with a concentrated extract of poison ivy. All test sites remained normal. Poison ivy does not grow north of the mouth of the St. Lawrence River. Straus,² applying similar tests, found newborn infants nonsensitive to this plant. I made patch tests of twenty-eight newborn infants confined in a foundling home. Not a single positive patch test developed during thirty days' observation. Approximately 50 per cent of young adults in the vicinity of Dallas, Texas, are sensitive to poison ivy, a plant with a high exposure index in this locality. Five per cent of all adults are said to be sensitive to the primrose plant (*Primula obconica*). Patch tests with an extract of this plant on 251 medical students, with no history of previous exposure, did not reveal a single positive patch test. Similar tests on twenty-five Dallas florists, who frequently handle this species of primrose, gave two positive reactions (8 per cent).

CLINICAL AND SUBCLINICAL SENSITIZATION

In the routine testing of persons with portions of the poison ivy plant I have repeatedly encountered test subjects who gave a mild to a moderate reaction at the site of the patch test but who did not develop ivy dermatitis following the ordinary clinical exposure of handling or walking through ivy vines. The greatest number of these reactions were observed when patch tests were done for a twenty-four hour period with the fresh ivy leaf or the dry plant meal.

Many of these subclinically sensitive persons were taken on field trips into ivy infested areas where they repeatedly handled the plant, walked through the trailing ivy vines, aided in the collection of ivy pollen, pinned ivy leaves to their clothing and the like, yet a subsequent dermatitis did not develop unless the bruised leaf was rubbed on their skin.

I have observed many instances of subclinical sensitivity to weeds. These persons give a mildly positive patch reaction to the antigenic weed and develop a subsequent dermatitis after massive exposure but do not develop a dermatitis following the ordinary clinical exposure of touching the offending herb.

PROCEDURE FOR EXTRACTING PLANT OLEORESINS

Mature green plants are collected, placed on paper and dried in a dark room to preserve the chlorophyll, which is useful as a coloring agent to delineate the patch site. After thorough drying, the plants are ground fine in order to extract the maximum amount of oil. The ground plant is packed loosely to within an inch of the top of a pint jar and covered with ether. The jar is sealed to prevent evaporation. The ether covered plant meal should stand for a minimum of twenty-four hours. The ether containing the dissolved plant resin is filtered and then placed in an open vessel to allow evaporation. The residue is a very sticky, viscid substance varying in color according to plant species from a very dark green to greenish brown or black. Dilutions are made by dissolving the crude resin in some fat solvent such as alcohol, ether or acetone. Dilutions are made by volume and not by weight. The 1:10 dilution, for example, is made by adding one part of the crude resin to nine parts of a solvent.

SITE CHOSEN FOR PATCH TESTING WITH OLEORESINS

In a patient of given sensitivity the cutaneous response to a patch test with a specific excitant is governed almost entirely by the thickness of the skin of the area tested. The simultaneous patch testing of various areas of skin shows that the most marked reactions are obtained at sites where the skin is thin, as in the cubital and popliteal fossae and the anterior portion of the neck. Tests on the skin of the thigh, arm, abdomen, chest and back give almost identical reactions but are of less severity than those encountered in the flexures. Reactions are markedly diminished or even entirely absent over the volar surface of the wrists, elbows and knees and the flexor surface of the ankles when these areas are thickened. In persons extremely sensitive to poison ivy I have never succeeded in obtaining a positive patch test on the palms or soles with the leaf, the plant meal or the 1:10 dilution of the oleoresin. After proper drying, the dorsa of the tongues and the palates of sixteen ivy sensitive patients were painted with the 1:10 dilution of the poison ivy oleoresin. Two persons gave a slightly positive reaction on the tongue; erythema and fine vesiculation of the palate developed in all. Reactions were reduced, since saliva acts as a diluent and also lessens adhesion of the oleoresin to the mucous membrane.

Since extracts of poison ivy and many other plants placed simultaneously on the arms, thighs and backs of clinically and subclinically sensitive persons produced approximately the same cutaneous response, the back was the site chosen for patch testing with plant resins.

METHOD OF APPLYING OLEORESINS

Dilutions of plant oleoresins in ether or acetone are placed in 4 cc. cork stoppered vials. Applications are made with the moistened end of the cork. The ether or acetone evaporates immediately, leaving a small quantity of chlorophyll stained crude resin in contact with the skin. Patch tests are placed on the back in vertical rows of ten, three rows on each side of the spinal column. The patch sites are not covered. Patients are warned not to scratch reacting areas, as small amounts of antigenic oleoresins may be transferred manually to other areas. Lines drawn between the vertical and horizontal rows of tests with an indelible pencil divide the back into small squares and aid in identifying patch sites. Sixty tests can be applied in approximately five minutes.

WEEDS EMPLOYED IN ROUTINE TESTING OF THE SKIN

During a period of six years, field trips have been made through Texas to ascertain which weeds individuals are most likely to come in contact with in work or play. Plants were chosen because of their distribution and abundance. Those with a high exposure index have been employed in routine testing of the skin until it has been definitely proved that they have a very low sensitizing index. Such weeds were then discarded and others substituted. It is a well known fact that any weed may cause a dermatitis in a sensitized person. The purpose of this study was not to discover every weed that might cause an occasional eruption but to find the major and minor skin sensitizing weeds just as allergists have determined the major and minor hay fever and asthma producing plants. The oleoresin of poison ivy has been used as a control in all our experiments. In the accompanying tabulation the reactions of

1. Heinbecker, P.: The Susceptibility of Eskimos to an Extract from *Toxicodendron Radicans*, *J. Immunol.* 15:365 (July) 1928.
2. Straus, H. W.: Artificial Sensitization of Infants to Poison Ivy, *J. Allergy* 2:137 (March) 1931.

CONTACT DERMATITIS—SHELMIRE

1087

only fifty-six weeds are recorded, since four or more tests on each subject have been done with miscellaneous oleoresins.

CONTROL TESTS

Skin Testing with Fresh Tissue Juices or Sap.—Before patch testing a large number of persons with the ether extracted plant oleoresins, it was deemed necessary to study the action of the fresh juices of these plants on normal persons.

If a drop of the milky juice of the mature poison ivy plant (*Rhus toxicodendron radicans*) is placed on the skin of a nonsensitive volunteer, this area immediately turns white as if painted with trichloroacetic acid. After a short period the area turns black because of the oxidation of the ivy juice. An eschar forms. This sloughs off in from eight to ten days. Complete healing with scar formation requires about two weeks. This juice has the same caustic effect for the skin of all animals tested—rabbits, guinea pigs and goats. When rabbits and guinea pigs were fed a meal consisting exclusively of fresh poison ivy leaves a crusting, irritative dermatitis of the lips developed. Immunity of man to poison ivy is relative. All degrees of dermatitis, from erythema to typical vesiculation, will develop on persons who have been proved clinically and subclinically nonsensitive to ivy after a latent period of from twelve to twenty-four hours if the amount of ivy sap applied to the skin is properly varied.

The milky juice of snow-on-the-mountain (*Euphorbia marginata*) has long been known to be irritating to both man and animal. When the juice of this plant is placed on the skin of a clinically nonsensitive person the area becomes erythematous almost immediately and there is a slight sensation of stinging at the contacted site. The erythema disappears rapidly but is followed after a latent period by a constant follicular papulopustular irritative reaction. The fresh tissue juices of the remaining weeds of this series (as shown in the tabulation) are not primary cutaneous irritants.

Skin Testing with Fresh Plant Leaves.—When clinically and subclinically nonsensitive persons submitted to patch tests with bruised fresh leaves of the weeds of this series, a large number of irritative reactions were encountered. During the early work with plants, the erythema and edema produced at sites patch tested for twenty-four hours with a plant leaf caused me erroneously to consider several persons plant sensitive. Subsequent tests showed absolute lack of both clinical and subclinical sensitivity. A twenty-four hour covered patch test with a fresh leaf, plant meal or ether extracted oleoresin is not an accurate test, since exposure to a plant is never continuous for twenty-four hours. It has been proved on numerous occasions that a patch test with the bruised plant leaf for a contact period of one hour or less will always occasion a positive patch reaction in both clinically and subclinically sensitive persons. Irritative reactions are not encountered in tests of such short duration.

Skin Testing with the Finely Ground Whole Plant.—The weeds of this series have been dried and ground to the consistency of meal. These plant meals have been found nonirritative to the skin of nonsensitive persons on twenty-four hour covered patch tests. Similar tests of such duration on weed sensitive persons reveal sensitizations that are of no clinical importance. When properly stored, plant meals retain their antigenic properties for at least four years.

Skin Testing with Water Extracts of Weeds.—Many weed sensitive persons volunteered the information that the plants to which they were sensitive "poisoned them more" if touched when wet with dew or rain. For this reason fresh water extracts of all the weeds in this series were tested on apparently normal persons. No positive patch reactions were observed. The water solubility of the dermatitis producing fraction (oleoresin?) of all weeds in the series could not be clinically determined since many did not prove antigenic for a single person. Of the weeds proved antigenic, the oleoresin of narrow leaved marsh elder was found rather markedly soluble in water as evidenced by the production of frankly positive patch tests when fresh water extracts of this plant were employed for testing sensitive persons. The oleoresin of such plants as dwarf ragweed, sneezeweed, parthenium, ironweed and gaillardia are moderately water soluble. The oleoresins of some plants, such as poison ivy, is absolutely insoluble in water. Water extracts deteriorate rapidly and lose their antigenic properties in one month or less.

Control Tests with the 1:1 Dilution of Weed Oleoresins.—Thirty-three apparently normal persons submitted to patch tests with the 1:1 dilution of all the oleoresins in this series except poison ivy. Five positive reactions were obtained in 1,815 (33×55) patch tests. These were considered irritative reactions since repeat tests with the 1:10 dilution of the same oleoresins gave completely negative reactions.

Control Tests with the 1:5 Dilution of Weed Oleoresins.—Forty-four apparently normal persons were tested with the 1:5 dilution of all oleoresins except poison ivy. Four moderately positive reactions were noted in 2,420 patch tests (44×55). When retests were made with the 1:10 dilution of the oleoresins, the very mildly positive reaction resulted. I believe that the latter reaction indicated subclinical sensitivity. Further tests were then done to determine the dilution of the extract which would indicate clinical and subclinical sensitivity without provoking irritative reactions.

Control Tests with 1:10 Dilution of the Oleoresins.—One hundred apparently normal medical students submitted to patch tests with the 1:10 dilution of all the plant oils. Fifty-two positive reactions were noted at sites tested with the ivy extract. The remaining patch areas were completely negative (5,600 tests).

Fifty proved cases of poison ivy dermatitis tested with all fifty-six oleoresins showed frank vesiculation at the sites of the poison ivy tests but negative reactions at the remaining patch areas (2,800 tests).

Thirty-seven persons with pollen hay fever or asthma but with no history of dermatitis were tested with the 1:10 dilution of all oleoresins except that of poison ivy. Not a single positive reaction occurred at any of the 2,035 test sites (55×37).

Fifty-seven persons with proved contact dermatitis from other excitants, such as cosmetics, crude oil and chemicals, submitted to patch tests with all the oleoresins except that of poison ivy. One showed mildly positive reactions to fleabane, camphor daisy and prairie Froelichia on the initial test and on three retests with both the 1:10 and the 1:20 dilution of the specific oleoresins. This person was considered subclinically sensitive to these three plants. The remaining fifty-six persons gave negative reactions at all patch sites (3,130 tests).

One hundred and eighty-seven persons with miscellaneous dermatoses such as drug eruptions, postarsphenamine dermatitis, bacterial allergies, urticarias and

eczemas of undetermined cause were similarly tested. Four mildly positive reactions were observed in 10,285 tests (187×55). I considered these reactions examples of subclinical sensitivity.

In the routine testing of persons clinically and subclinically sensitive to poison ivy with the 1:10 dilution of the oleoresin I have never failed to obtain a frankly positive patch reaction. Conversely, I have never encountered a positive reaction with this dilution when testing persons proved nonsensitive. Since the 1:10 dilution of the crude plant extract does not act as an irritant yet never fails to evoke reactions in both clinically and subclinically sensitive persons, this was the dilution chosen for routine patch testing.

TRANSEPIDERMAL ABSORPTION OF PLANT OLEORESINS

When weed sensitive persons were tested on unbroken areas of skin by the uncovered method, many developed an apparent flare-up of the eruption. Focal flare-ups did not occur when the same persons were retested and the patch sites were completely covered to prevent manual transference of the oleoresin. Three patients who submitted to patch tests with the specific oleoresin on excoriated areas developed not only a focal flare-up of the eruption (vascular type reaction) but also an ephemeral maculopapular urticarial type of reaction over unaffected areas of the trunk. In addition, one of these subjects presented a vesicular "id" eruption of the palms and soles.

I have repeatedly encountered focal flare-ups of the eruption and generalized urticaria during co-seasonal attempted hyposensitization therapy when the specific oleoresin was given orally or intramuscularly.

FLARE-UP OF HEALED PATCH SITES

Focal flare-ups observed in weed sensitive persons who were tested on areas of unbroken skin by the uncovered method can be explained only by the transference of minute quantities of the specific oleoresins manually from pruritic reacting sites on the back to distant areas. These small amounts of oleoresin caused a definite flare-up of the supersensitized areas of healing or recently healed dermatitis but were not of sufficient strength to evoke a dermatitis on the normally sensitized unaffected skin.

In an effort to determine the duration of supersensitization of areas of previous dermatitis, weed sensitive persons were patch tested with serial dilutions of the specific oleoresin in corn oil. Those dilutions which evoked positive patch reactions on previously unaffected areas of skin were termed reactive concentrations of the oleoresin. Dilutions too weak to evoke such a positive response were termed subreactive concentrations. By painting the patch areas and the surrounding skin with subreactive concentrations of the specific oleoresins I have repeatedly been able to bring about a flare-up of patch sites completely healed for months. In one ivy sensitive person I was able to bring about a flare-up of a patch site healed for one year.

I am convinced that sensitization to an external agent is always general, the skin and mucous membrane alike being involved. The difference in sensitization of different areas of both skin and mucous membrane (mouth only site tested) is relative. True local sensitivity to an external agent does not occur.

Healing and completely healed patch sites are often metallergic in that they can be caused to flare up by the application of nonspecific plant oleoresins, adhesive tape

and the like. An oleoresin which evokes only a very mildly positive reaction on a previously unaffected area will frequently cause a frankly positive reaction if applied to a recently healed patch site which was originally evoked by a totally different plant extract. Patch sites are parallergeric in that an urticarial flare-up of healing and recently healed areas often follows positive Dick, Schick and tuberculin reactions. Healing and recently healed patch sites are frequently rather markedly dermatographic, rubbing causing an urticarial flare accompanied by intense pruritus of the site (release of H-like substance?). This may account for the paroxysms of itching in many eczemas—especially the infantile type in which hospitalization and restraint are followed by a rapid amelioration of symptoms.

When a dermatitis is present, even though caused by positive patch tests, general sensitivity to other weeds is increased. At such times, patch tests on unaffected skin will result in frankly positive reactions to weeds that previously evoked doubtful or very mildly positive reactions. This increased general sensitivity disappears rapidly after healing of the original dermatitis.

ADHERENCE OF PLANT OLEORESINS TO SKIN OR COMBINATION OF ANTIGEN WITH FIXED CELL ANTIBODIES

It is generally believed that if clinical exposure to poison ivy is followed within a few hours by thorough washing with soap and water or sponging with tincture of ferric chloride or solution of potassium permanganate, the subsequent ivy dermatitis will be entirely prevented or markedly lessened. Believing this empiricism, I carried out experiments to determine just how soon it was necessary to use these prophylactic measures to prevent dermatitis. A leaf of poison ivy was gently rubbed on the forearms and a 1:10 dilution of the ivy oleoresin was painted on the upper arms of ivy sensitive persons. Four hours later these areas were thoroughly washed with soap and water. Frankly vesicular reactions followed. The contact time with the leaf and the 1:10 oleoresin was then shortened by hours, then by half hours, quarter hours and finally minutes. We had evidently started at the wrong end of the experiment. A contact period of one minute or less followed by thorough washing with soap and water for five minutes, with frequent interval spongings with ether, alcohol and carbon tetrachloride, was invariably followed by a dermatitis. With this extreme washing the reaction was frequently of less severity and the latent interval usually somewhat prolonged.

Similar tests carried out with tincture of ferric chloride and 10 per cent solution of potassium permanganate clearly demonstrated the fact that these agents are less effective than cleansing with soap and water. Ten per cent poison ivy extract, with tincture of ferric chloride as a diluent, retained its antigenic properties for several days.

An ordinary clinical exposure to ivy by a sensitive person was followed within five minutes by thorough washing of the involved area with laundry soap and water for ten minutes. Forty-eight hours later a typical vesicular ivy dermatitis in streaks and patches developed on areas touched by the ivy plant.

In weed sensitive persons, in whom sensitization is usually not so extreme, thorough washing usually prevents a positive patch reaction if the antigenic oil is left in contact with the skin for less than five or ten minutes.

PHOTOSENSITIZATION

Such plants as meadow grass, fig, bergamot and gas plant are known to be photosensitizers. Since plant oleoresins are applied to the back in routine testing and are thereby exposed to diffused daylight during the application and drying time, photochemical action of the weeds included in our list was considered. When any weed oleoresin produced a positive reaction, the test was immediately repeated and the test site covered to exclude all light. As positive reactions occurred before removal of the covering material, photodynamic action of the plant was eliminated. By the same patch method it was proved that the chlorophyll contained in all our plant oleoresins played no part in causing positive reactions.

Animals with white skins, such as certain horses, cattle and hogs, are known to develop a dermatitis after the ingestion of various weeds and subsequent exposure to the sun. No evidence of photosensitization has been observed in some twenty-five weed sensitive patients given the specific weed oleoresins intramuscularly or orally over a period of months in attempted preseasonal desensitization.

INDUCED SENSITIZATION FROM REPEATED
PATCH TESTING

Eleven volunteers previously proved, by patch testing, nonsensitive to poison ivy were tested daily for six weeks with the 1:10 dilution of ivy extract. Fourteen persons proved nonsensitive to the weeds of this series submitted similarly to patch tests every day to every third day for a period of two months with extracts of the seven most sensitizing weeds of this series (see tabulation). No evidence of induced sensitization was observed in any of these volunteers. Twenty-eight newborn babies were tested with the 1:10 ivy extract and retests were done twenty-three days later. No positive reactions were observed following either testing.

Many weed sensitive persons who have completely avoided natural contact with weeds for a period of months or years have repeatedly been retested with the 1:10 dilutions of plant extracts. Induced sensitization did not follow these repeated patch tests. I believe that testing with the 1:10 dilution of a plant extract constitutes no greater exposure than the patient experiences daily in his routine work.

Individuals vary greatly as to their susceptibility to artificial sensitization. Employing a 1:10 or higher concentration of poison ivy extract for the sensitizing material, my associates and I have easily sensitized many persons to this plant. Induced sensitization has occurred in others only after prolonged application of the extract. Some persons seem completely refractory to sensitization, regardless of the concentration of the extract employed or the length of time it is left in apposition with the skin.

The sensitizing power of plants likewise varies markedly. Although we have readily sensitized persons to poison ivy, to date we have no record of induced sensitization to any other plant of this series.

Many weed sensitive patients who gave a mild delayed reaction to a specific oleoresin submitted to patch tests once or twice weekly with this plant oil for a period of from weeks to months. In some individuals it was possible to increase definitely their sensitivity to these oleoresins by repeated patch testing. This was evidenced by a shortening of the latent period between the application of the test and the cutaneous response and by an increase in the severity of patch

reactions. In other individuals it has been impossible to increase the sensitivity by repeated patch testing with the specific excitant.

DELAYED PATCH REACTIONS

In the patch testing of persons of unknown sensitivity, a reaction delayed longer than seven days is empirically considered evidence of a single patch test serving as both the sensitizing and the activating application of the excitant. The interval between the application of the test and the appearance of the cutaneous reaction is considered the period of incubation of sensitivity.

During the testing of persons known to have suffered an ivy dermatitis years previously, I have seen patch reactions delayed until the tenth or eleventh day. Such delayed reactions must be considered as patch reactions delayed beyond seven days, or examples of a natural loss of sensitization with resensitization from a single application of the patch.

During the testing of persons of unknown sensitivity with the 1:10 dilution of ivy extract we have repeatedly seen positive reactions appear first between the seventh and the twenty-third day after testing. Fourteen such persons were immediately retested with the 1:10 or higher dilution of the ivy oleoresin. In twelve of these cases the latent period of subsequent reactions was always seven days or less. One patient regularly gave a positive reaction on the fifth or sixth day when tested with the 1:10 dilution, but positive reactions were delayed until the eighth, eleventh and seventh day respectively when three retests were done with the 1:20 or higher dilution. The last member of the group gave a positive reaction on the fifteenth day following the first patch test. A second patch applied one week later did not become positive until the eleventh day. During the routine patch testing of markedly sensitive persons with high dilutions of the specific oleoresins (1:1,000 to 1:1,000,000) I have repeatedly seen reactions to patch tests delayed to the seventh or eighth day following testing. Tests delayed to the twelfth day have been recorded by patients but not observed by us. From these experiments it appears that a patch reaction may be delayed beyond the empirical seven day limit of latency.

DERMATITIS FROM INTERMEDIARY CONTACT

During the past six years an attempt has been made to trace the source of ivy dermatitis when direct exposure to the plant was denied by the patient. It has been proved that dermatitis often follows contact with such ivy contaminated intermediary objects as shoes, clothing, heads of golf clubs, work tools, door knobs, steering wheels of automobiles, pets, and hands of other persons who had touched poison ivy. I have repeatedly gathered poison ivy, thoroughly washed my hands with soap and water and then at intervals rubbed the skin of ivy sensitive persons. The hands retained, up to six hours, sufficient oleoresin to evoke a dermatitis.

In tracing the source of recurrences in weed eczemas, positive patch tests have been obtained from hat bands, hay, unginced cotton, and scrapings from boots and shoes. These articles were antigenic for other weed sensitive persons but not for control subjects. Seven cases of so-called milkers' eczema have been proved by properly controlled patch testing to be due to weed oleoresins on the bellies and udders of cows and not to cow hair itself. Sheets are frequently contaminated by work clothes during a midday rest.

CONTACT RHINITIS

Three persons with contact dermatitis from weeds complained of a crusting rhinitis during the pollinating season of the plants to which they were sensitive. One of these patients was retested during the interseasonal period of the dermatitis. When the mucous membrane of the nares was painted with a 1:1,000 dilution of the specific narrow leaved marsh elder oleoresin, a vesiculation followed after twelve hours. One drop of 1:50 dilution of the extract placed on the tongue was followed by redness and slight swelling after a similar latent period. Narrow leaved marsh elder, a plant which produces a large amount of pollen, covered this patient's farm and grew almost to her doorstep.

POLLENS LESS ANTIGENIC THAN REMAINDER
OF PLANT

It has been stated that the anthers of many species of the sumac family contain no resin ducts. Their pollen therefore could not contain the antigenic oleoresins.³

I collected enough uncontaminated pollen of *Rhus toxicodendron* radicans to test eight ivy sensitive persons repeatedly. All patch tests with this pollen and its anthers gave entirely negative results.

The pollens of many weeds in this series seem much less antigenic than other portions of the plant. This antigenic variation between the plant and its pollen can best be gaged on moderately sensitive persons. Patch tests on such patients with the fresh leaf, meal or extract will reveal a moderately positive test, while the pollen will frequently give a frankly negative reaction. One Gm. of the specific antigenic pollen blown directly on the moistened faces of weed sensitive persons from a distance of 18 inches failed to cause a dermatitis.

Observation of weed dermatitis indicates that pollens play a minor role in the causation of this condition. Eruptions may be exaggerated during pollen storms or when the individual closely approaches pollinating weeds on windy days. I believe that the apparent increase in severity of a dermatitis during the pollinating season is due to a greater oleoresin content of weeds at that time.

PASSIVE TRANSFER EXPERIMENTS

All attempts to demonstrate antibodies in blood serums of weed sensitive persons by the Prausnitz-Küstner method of passive transfer have failed. Blister fluid of weed sensitive patients injected intradermally into control subjects did not sensitize the injected sites. Blister fluid incubated with the specific oleoresin for twenty-four hours did not give a positive patch reaction on nonsensitized persons. With the aid of Dr. J. H. Black, 1 square centimeter or more of skin was excised from each of five plant sensitive patients, ground with sand and saline solution, passed through a Seitz filter and injected intradermally or tattooed into the skin of nonsensitive controls. The injected sites were then patch tested with the 1:10 dilution of the specific oleoresin. Three such tested sites were entirely negative. Mottled erythema developed at two test sites on the third and fifth days respectively.

SUMMARY

Contact dermatitis from weeds may be acute but is usually chronic, persisting for many years during the growing period of plants. The exposed areas are chiefly affected and healing time after avoidance of

contact with the offending plant is prolonged. Sensitization to plants is apparently general, both skin and mucous membrane being involved. Sensitization may be either clinical or subclinical. Patch testing with plants may be greatly facilitated by employing their ether extracts for testing material.

THE PATHOGENESIS OF CRISIS AND
DEATH IN HYPERTHYROIDISM

HAROLD L. FOSS, M.D.

HENRY F. HUNT, M.D.

AND

ROBERT M. McMILLAN, M.D.

DANVILLE, PA.

The physiology of the thyroid gland is probably as well understood as that of any organ of the body, yet there is much that is not clear with regard to the many pathologic states which result in disordered function of this organ. There has been difficulty, particularly in understanding that curious state referred to as thyroid crisis, a condition often terminating in death either prior to or, frequently, after operation, the pathogenesis of which is rarely made clearer by postmortem examination. In this state it is obvious there are profound toxemia and a violent and overwhelming disturbance of metabolic processes with, no doubt, a profoundly altered blood chemistry if, as remarked by Maddock,¹ "one only knew what to measure."

Twenty years ago it was not uncommon for patients to be admitted to the hospital in active crisis and to succumb rapidly in spite of treatment. As patients and physicians have increasingly realized that much can be done for hyperthyroidism, such situations have become less common, but, while the incidence of postoperative crisis has fallen to an apparently irreducible minimum, the condition yet occurs even in the best of clinics and after most careful preoperative preparation and most meticulous planning of operative procedures as a harrowing and frequently fatal complication. When crisis, under these circumstances, does develop it usually appears unexpectedly, the point being frequently made that, when death does occur, the surgeon, had he exercised greater foresight, could have prevented it. Yet patients who seem to present the most serious risks frequently go through an extensive thyroidectomy without reaction, while others who may seem to be in far better condition rapidly succumb, usually within forty-eight hours, to that curious and yet unexplained condition referred to as postoperative hyperthyroid crisis. Semiconsciousness, extreme restlessness, uncontrollable even after heavy sedation and accompanied by an uncountable pulse, frequently cyanosis, delirium and finally death compose the picture. No one has as yet determined the basal metabolic rates under these circumstances. Nothing but a spurious result could possibly be obtained because of the patient's extreme restlessness. In all probability, the oxygen consumption and heat production become far greater than in any other disease known.

From the Departments of Surgery and Pathology of the George F. Geisinger Memorial Hospital.

3. McNair, J. B.: *Rhus Dermatitis: Its Pathology and Chemotherapy*, Chicago, University of Chicago Press, 1923.

What to do for the patient once the condition has presented itself or, more important, how to prevent its occurrence are questions of the greatest importance in the surgical treatment of toxic goiter.

It is logical to believe that, given two large groups of patients from widely separated clinics where the surgical experience has been extensive and the surgeons have given sedulous and long continued study to the problems of thyroid disease and are of equal skill, there may be a difference in mortality attributable to factors entirely related to the patients, to the habitual delay in accepting treatment or to the patients' or physicians' neglect in accepting adequate surgical care for known toxic goiter. Statistics from large clinics will show that with an increase in the number of patients with any particular disease the relative mortality is constantly decreased owing, to a certain extent, to numerical factors alone. The surgical center drawing patients from far flung rural areas is faced with the problem of handling advanced disease, in whatever area of the body it may be located, to a far greater degree, we believe, than is the urban clinic, whose patients are far more inclined to accept surgical relief earlier than is the patient of the hinterland.

Good surgical care of thyrotoxic goiter demands thorough and painstaking study of the patient by the clinician, surgeon, cardiologist and laboratory worker, whose judgments in evaluating the condition and in planning the treatment to be carried out are combined in the interest of the patient. If adequate preoperative preparation has been conducted, with the use of such drugs as are indicated, with proper sedation and with the maintenance of water balance, all leading to a skilfully planned, timed and performed operation, followed by meticulous watchfulness in the postoperative period, and death ensues—what then?

Bayley² reported that fifty-one of 123 deaths due to toxic goiter in the University of Michigan Hospital were preoperative. Eight patients were admitted in severe crisis, six died after operations on organs other than the thyroid, eight died of crisis induced by acute infection, nine died after minor diagnostic procedures such as abdominal paracentesis and spinal puncture. Goetsch³ analyzed twenty-two deaths following 1,755 operations. Eight patients died after operation; others, before surgical measures could be carried out, died of pneumonia, embolism or primary cardiac failure and crisis. With deaths from goiter, crisis accounts for more than one half the mortality. Seventy per cent of the goiter deaths at Ann Arbor, as reported by Maddock,¹ were due to this cause, about one half occurring before operation. A like preoperative frequency was reported by Lahey⁴ in 1928.

Of eighty-eight deaths studied by Ransom and his associates,⁵ fifty-one occurred preoperatively and thirty-seven after partial thyroidectomy. In thirty-one cases a bilateral resection or subtotal thyroidectomy was performed. Obviously, as the authors conclude, these were examples of too much surgical intervention. In their series no deaths followed pole ligations and no deaths followed removal of the remaining lobe when stage operations were performed. Yet in our experience deaths have occurred in several instances after

pole ligations, even single ligations, and after unilateral resections, from six weeks to two months after ligation and even when the program of preoperative treatment had been most watchfully carried out. That the patient's condition on the table is rarely an index of what the postoperative period will reveal is a fact frequently mentioned and certainly one thoroughly established in our minds.

Kroger and Toland⁶ had twenty-seven fatalities in 2,070 cases—all but two of the patients having single stage operations—another example of too much surgical intervention resulting in an unnecessary mortality. Eleven of their patients died in crisis; the authors, in retrospect, were convinced that many could have been saved by graded operative procedures and remarked that "there is no code, no laboratory procedure that will indicate the exact toxic state." They expressed agreement with many that the pulse rate is probably the one best single index of the intensity of the toxemia.

The factors precipitating severe reactions terminating in death vary but little according to the reports of all recent investigations. Delay, inadequate preoperative preparation, surgical procedures not properly planned, infection, minor diagnostic and therapeutic procedures, an age of 60 or more, emaciation, a basal rate which fails to fall materially, even after prolonged treatment, a loss of weight of 40 pounds (18 Kg.) or more, toxic goiter of from ten to fifteen years' duration, interminable medication with iodine—all these have been emphasized recently by Ransom and Bayley.⁵ These authors feel that the anesthetic is not an important factor, at least not nearly as much so as the time and the extent of the operation, an opinion to which we fully subscribe.

It has been suggested that in crisis there is a depletion of sodium or a change in the serum potassium, yet at Ann Arbor normal potassium values were found for fifteen patients seriously ill from hyperthyroidism. Also normal calcium and phosphate values were found for most patients with toxic goiter. In a study by Svend Pedersen and his co-workers,⁷ the work of Schneider⁸ on the serum sodium content in relation to hepatic damage in hyperthyroidism was not confirmed; in other words, it was apparent to these workers that determinations of the serum sodium have no value in relation to hyperthyroidism. Maddock and his co-workers¹ concluded that searches for abnormalities in inorganic ion concentrations in the blood "have not been fruitful."

We have noted that the accumulation and expectoration of mucus are common, probably because of traumatic tracheitis. Maddock¹ has mentioned the possibility of the condition being due to an increase in circulating epinephrine. Although Bouchard and Claude⁹ observed pulmonary edema in rabbits after injection of epinephrine, there is nothing to prove that the collection of mucus in the larger bronchi, so frequently noted in crisis, is due to abnormal adrenal activity. It seems more probable that the edema is due to tracheitis, cardiac failure and, frequently, bronchopneumonia. In the studies of Maddock¹ no positive identification of

substances yielding to the biologic reactions similar to those of epinephrine were found.

Death after operation on the thyroid, provided there has been adequate preoperative preparation, almost always follows too much surgical intervention. As stated by Clute,¹⁰ the "mortality increases as the percentage of one stage operations increases." This author remarks that unexpected deaths after the age of 40 are

usually of patients who have had the disease more than one year, who have lost large amounts of weight and who are extremely emaciated.

PATHOLOGIC ANATOMY

Neither the physiologists nor the pathologists working in the laboratory or autopsy room have been able to cast definite light on the mechanism of hyperthyroid crisis. One rightfully expects precise organic changes characteristic of this complication to be readily discoverable on postmortem examination or on microscopic study of the tissues, but so far this has not been the case.

Heart.—For years it was believed that the cause of death, as suggested by the characteristic tachycardia, the arrhythmias and the uncountable pulse, was cardiac in origin, yet the results of autopsy are surprisingly negative so far as the heart itself is concerned.

In 1886 Moebius,¹¹ stimulated by Parry's¹² classic communication, suggested the causative association of the thyroid with the disease which is now called hyperthyroidism. Because of the prominent cardiac symptoms, Moebius¹¹ was led to remark that "Basedow patients die through their hearts." Many theories were advanced to explain the cardiac involvement, particularly the hypertrophy, which is so common. The idea that the hypertrophy was secondary to compression of the trachea and the great vessels in the neck was championed by many investigators. This theory that mechanical alterations were responsible for cardiac hypertrophy was sponsored particularly in Bavaria, Switzerland and the Tyrol, where large colloid goiters are common. However, Kraus,¹³ in a series of papers between 1889 and 1906, pointed out that rapid and

forceful heart action could occur in patients who did not have the slightest evidence of tracheal obstruction. From these observations Kraus¹³ attempted to establish the thyrotoxic heart as a clinical entity. He further made a distinction between the cardiac hypertrophy often observed in patients with a large colloid goiter and the toxic heart found in patients with hyperthyroidism. The first he referred to as "goiter heart," while the second he called "thyrotoxic heart." Chvostek¹⁴ substantiated the observations of Kraus¹³ and expressed the opinion that "only in severe cases of exophthalmic goiter is there hypertrophy of the heart."

In 49 per cent of eighty-nine fatal cases of hyperthyroidism without evidence of hypertension or complicating cardiac disease, Kepler and Barnes¹⁵ found that the weight of the heart exceeded maximal standard values calculated on the basis of the patient's weight prior to illness. In twenty-seven of 178 fatal cases they observed congestive failure. In eighteen (67 per cent) there was evidence of coronary sclerosis, hypertension, acute or chronic pericarditis, rheumatic endocarditis or syphilis. In the remaining cases no cause other than hyperthyroidism was found to account for the hypertrophy.

It is obvious that heart disease frequently exists prior to the development of the hyperthyroidism, yet in some instances the cardiac symptoms seem secondary to the extra work thrown on the myocardium by the tremendously increased metabolism. Auricular fibrillation occurs with increasing frequency in each ascending decade and is present in practically all cases of congestive failure.

The experimental evidence that thyroxine has a selective action on heart muscle is none too convincing. Hashimoto,¹⁶ Goodpasture¹⁷ and Takane¹⁸ observed degenerative changes in the heart muscle cells which they thought due to the specific action of thyroxine. On the other hand, Cameron and Carmichael¹⁹ and Rake and McEachern²⁰ concluded that no significant alterations are produced in the heart by experimentally induced hyperthyroidism.

Liver.—Beaver and Pemberton²¹ found a high incidence of degenerative changes in the liver of patients dying in crisis. Weller²² discovered some hepatitis at autopsy in twenty-two of forty-four selected cases of exophthalmic goiter, finding a like situation in but one of a control series of the same number of cases. Of the Ann Arbor series of patients with hyperthyroidism, 61 per cent showed impaired hepatic function—a condition becoming increasingly more pronounced after operation. Similar observations have been reported by other writers, Frazier,²³ Lahey,²⁴ Bartels²⁵ and Beaver

and Pemberton.²¹ The last mentioned authors presented two theories of the causes of reactions: (1) a sudden increase of thyroid secretion and (2) hypersecretion of epinephrine. Goetsch and Ritzmann²⁶ point out that the common reactions can all be produced by administration of epinephrine; however, Maddock and his associates¹ conclude that (1) preoperative studies of the hepatic function give no indication of the mildness or severity of the postoperative course and (2) in the postoperative period there is an increase in the impairment of hepatic function, with an increase in hyperthyroid reactions, but no evidence to show that one is the cause of the other. Lesions in the liver appear to be an integral part of the syndrome of severe toxic goiter.

The question remains unanswered, however, regarding the cause of these changes. From the standpoint of the pathogenesis of death in goitrous patients, therefore, it appears important to determine whether the lesions occur primarily or as secondary manifestations of profound toxemia.

Thymus.—The thymus gland, because of its intimate relationship to the thyroid, has attracted the attention of many workers. The rapid development of the syndrome known as thyroid crisis and the frequent, often sudden, death of the patient have led to the belief that the complication may be associated in some way with a dysfunction of the thymus. While so-called thymic death does not resemble in many respects death from

being those of Matti,²⁸ MacKenzie,²⁹ Blackford and Freligh,³⁰ Crotti,³¹ Giordano,³² Potter³³ and Margolis.³⁴ Blackford and Freligh,³⁰ in a study of 117 necropsies on patients who had had thyroid disease, found hypertrophy of the thymus in every patient under 40 years of age with a hyperplastic gland and in every patient under 30 years of age with a nonhyperplastic gland. They considered thymic hypertrophy and lymphoid hyperplasia a result of the intoxication rather than a

contributing factor in it. Margolis,³⁴ in a more recent postmortem study of eighty-five cases of thyroid disease, observed hyperplasia of the thymus gland in 85 per cent of the patients with exophthalmic goiter and in 53 per cent of the patients with adenomatous goiter. He concluded that the possible significance of the hyperplasia may represent a constitutional, inherent disposition to the development of hyperthyroidism.

CAUSE OF DEATH IN TWENTY-NINE CASES

At the Geisinger Memorial Hospital, in the past twenty-three years, ninety-six patients suffering from thyroid disease have died. Postmortem examinations were made of twenty-nine of these patients. The diagnosis of exophthalmic goiter was made for eleven, the diagnosis of nodular toxic goiter for thirteen and the diagnosis of nodular nontoxic goiter for one. For the remaining four the diagnosis was carcinoma.

Death in nine of the twenty-nine cases was obviously due not strictly to thyroid crisis but to associated conditions fully recognizable before death. In this group the following diagnoses were made: adenocarcinoma (four), cerebral hemorrhage (one), tracheal obstruction, abductor palsy (one), diabetes mellitus (one), infarct of the left lung (one) and secondary hemorrhage, postoperative (one).

The immediate cause of death in twenty of the twenty-nine cases was, clinically, crisis. However, in nine the necropsy indicated that other conditions were responsible for the patient's death. In each of these there was present an overwhelming infection, antedating the symptoms of crisis and being of sufficient magnitude to be considered the principal cause of death. The following conditions were recorded at necropsy: multiple abscesses of kidneys, acute mitral endocarditis, strepto-

thyroid crisis, the majority of patients dying in crisis will be found, at autopsy, to have a persistent and hypertrophied thymus.

The first report of the association of a hypertrophied thymus with thyroid disease was made by Markham²⁷ in 1858. Numerous reports confirming his observations are found in the literature, the most comprehensive

coccic septicemia, acute purulent pericarditis, miliary tuberculosis, empyema and, in four instances, bilateral bronchopneumonia.

The eleven cases in which no other death producing factor was found can rightfully be considered instances of true "thyroid crisis" death, and it is this group that warrants particular study.

As has been mentioned, postmortem examination has been directed especially toward the heart, liver and thymus. The bulk of recorded observations have largely been limited to these organs and, as we observed no significant changes elsewhere, we will consider these organs particularly.

A normal heart was found in three patients who died in crisis. The remainder showed one or more gross or microscopic changes, always associated with other evidence of cardiovascular diseases. Five of the hearts were hypertrophied, while seven showed varying degrees of myocardiofibrosis. In four hearts the coronary arteries were sclerotic, and in one there was found healed mitral endocarditis. Myocardosis occurred five times and always in subjects who showed evidence of toxic changes in the parenchymatous organs.

From a correlation of our clinical and postmortem studies we believe that there is not sufficient proof to indict the heart as the primary site of the difficulty in patients in whom thyroid crisis develops. Certainly such patients may die a so-called cardiac death, but, in the absence of specific myocardial lesions, it is safe to assume that the heart failure is on a physiologic rather than a pathologic basis.

There was but one normal liver in the cases of true crisis death. Ten of the eleven subjects showed varying degrees of necrosis in the center of the lobules. There were eight necropsies in which fatty degeneration of the liver cells was a prominent feature. This change was more marked in the livers in which necrosis was extensive. Cellular infiltration was present in three organs and congestion in one, the latter occurring in a patient who had healed mitral endocarditis.

Our attempt to correlate the degree of injury to the liver with the degree of toxemia was unsuccessful. The usual association of hepatitis with thyroid disease cannot be disputed, but, as mentioned in a preceding paragraph, it has not been determined whether the changes in the liver occur as primary or as secondary manifestations.

Hypertrophy of the thymus was found in fourteen of the twenty-nine patients. For nine there was found no cause of death other than crisis. The remaining five had hyperplastic thyroids but had died not in crisis but as the result of severe infection.

Our observations so far as the heart, liver and thymus are concerned are in agreement with the majority of the reports of similar studies. It is apparent that the pathologist has little more to offer, and it remains for the physiologist and experimental pathologist to discover the true nature of the toxemia that is responsible for the "thyroid crisis" death.

CONCLUSIONS

1. The mechanism of hyperthyroid crisis is as yet but little understood.

2. Neither the heart, liver, thyroid nor thymus seems, alone, to be at fault.

3. That acute hepatic insufficiency is a contributing factor is accepted, but there is not definite evidence to prove that it has the major role.

4. Sudden death soon after so slight a trauma as that of pole ligation cannot be accounted for entirely by damage to the liver.

5. That there is extreme stimulation of cellular metabolism, the exciting factors of which are little understood, is generally believed. There is, however, no proof that these follow sudden hypersecretion of thyroxine, epinephrine or both.

6. Evidence points to acute dysfunction not only of the thyroid but possibly of other glands of the endocrine system, including the pituitary.

7. Postoperative crisis in association with typical exophthalmic goiter is now uncommon. Today unexpected postoperative deaths are largely confined to aged patients suffering from long standing nodular goiter, usually associated with cardiorenal-vascular disease.

8. While myocardial degeneration may, and does frequently, result from long standing hyperthyroidism, it is coexisting myocardiocardiovascular degeneration plus some unknown factor or factors associated with acute hyperthyroidism which combine in producing crisis causing death.

9. The pathologist has cast no definite light on the pathogenesis of crisis. Neither does he explain sudden postoperative death in cases of toxic goiter. There is much yet to be elucidated by the physiologist and experimental pathologist before the pathogenesis of postoperative hyperthyroid crisis is understood.

TUMORS OF LATERAL ABERRANT THYROID ORIGIN

GEORGE CRILE JR., M.D.

CLEVELAND

Lateral aberrant thyroid tumors occur as the result of an anomaly in the development of the thyroid gland. Histologically these tumors are not composed of normal thyroid tissue but have a papillary structure indistinguishable from that of papillary tumors of the thyroid.

In forty-five of the 136 reported cases of tumors arising in lateral aberrant thyroid tissue, as shown in the accompanying table, the growth has been classified as malignant. Yet only two of the forty-five patients have been reported to have died as a result of recurrence of the tumor following operation. In no case has either local or distant metastasis of the tumor been proved. The remarkable survival record of the patients cannot fail to raise the question of whether or not the tumors were true carcinomas.

Many of the tumors in the collected series were described as showing extensive metastasis to the cervical lymph nodes. Similarly it has been repeatedly stated in the literature¹ that metastasis to the regional lymph nodes is commonly seen in patients with papillary carcinomas of the thyroid. In more than fifty cases of papillary tumors of the thyroid observed at the Cleveland Clinic there has been no demonstrable metastasis to lymph nodes.²

Recently it has been recognized³ that in the presence of lateral aberrant thyroid tumors the thyroid gland is apt to contain, coincidentally, one or more papillary

tumors similar to those in the lateral cervical regions. It is thus difficult to differentiate between (1) a papillary adenoma of the thyroid associated with multiple papillary adenomas originating in lateral aberrant thyroid tissue and (2) a papillary carcinoma with metastasis to the cervical nodes. Histologically there is little to differentiate the two.

There is a striking tendency for lymphoid tissue to be present in all lateral cervical sinuses, cysts and other embryologic anomalies of the neck. Lateral aberrant thyroid tumors are no exception to this rule, as they also tend to contain considerable lymphoid tissue and may have the histologic appearance of a lymph node containing metastatic carcinoma. The final answer to the question as to whether these tumors are benign primary tumors or metastatic carcinomas must be decided by the clinical course of the disease and the survival of the patient. Since there is no case either in our series or in the remainder of the literature in which the tumor has continued to disseminate itself after operation and has thereby caused the death of the patient, it would appear that these tumors are essentially benign and should not be classified as metastasizing carcinomas of the thyroid.

CLINICAL MATERIAL

In the past fifteen years, seventeen patients with tumors arising in lateral aberrant thyroid tissue have been seen at the Cleveland Clinic. Three cases in this group are of particular interest:

CASE 1 (illustrating the wide distribution of lateral aberrant thyroid tissue).—A married woman aged 27 complained of a painless lump in the posterior triangle of the neck just above the clavicle. Examination showed a slight, firm enlargement of the left lobe of the thyroid, multiple soft movable tumors in the posterior triangle on the left and several small soft nodules deep in the sternomastoid muscle on the right. A clinical diagnosis of tuberculous glands, possible lateral aberrant thyroid tumors, was made and one of the nodules was removed for microscopic examination.

The nodules were papillary adenomas arising in lateral aberrant thyroid tissue. At operation, twenty-five separate nodules were dissected out of the neck and the left lobe of the thyroid was completely removed. This lobe showed diffuse papillomatosis extending medially nearly to the isthmus.

The patient was well one year after operation.

This case is of interest not only because of the large number of lateral cervical nodules that were present but also because of the diffuse papillary adenomatosis of the left lobe of the thyroid. The entire lobe was involved not by a discrete papilloma but by a papillomatosis in which the tumor cells were growing in and through the normal thyroid tissue. This condition suggests that the papillary tumors are of multicentric congenital origin, originating perhaps from rests of the lateral thyroid anlage which normally disappear completely during embryonic life.

CASE 2 (illustrating the slowness of the tumors' growth).—A woman aged 22 had noted a painless lump in the neck six months prior to entry. A diagnosis of tuberculous glands was made and a course of high voltage roentgen treatment was given without improvement. Two glands about 2 cm. in diameter were palpable in the left side of the neck. One of these was removed (by Dr. T. E. Jones) and the pathologist reported the tumor as a papillary adenoma of lateral aberrant thyroid origin.

The patient was not seen again for thirteen years. In response to a follow-up letter she returned, complaining of recurrent nodules in the neck. Examination showed multiple nodules behind the sternomastoid muscle on each side, a firm

midline nodule above the isthmus of the thyroid and bilateral firm tumors in the thyroid itself. These tumors were enlarging slowly, but not one was over 4 cm. in diameter and no symptoms of pressure had been noticed. Operation was advised.

The slowness of the growth of such tumors is evident in this case, in which there had been only a slight enlargement in thirteen years. The case is of interest also because of the extensive bilateral distribution both in the thyroid and in the lateral cervical region.

CASE 3 (illustrating the eventual fatal outcome in a case in which surgical intervention was delayed too long).—A man aged 57 had had a large papillary adenoma of the right lobe of the thyroid removed eight years before entry. The tumor gradu-

ally recurred and in the past two years had grown rapidly. At the same time a rapidly growing tumor appeared on the left side of the neck. He had been given a course of high voltage roentgen therapy without relief of his symptoms or change in the size of the tumor.

Examination showed an obese man in marked respiratory distress. There were inspiratory stridor and a brassy cough. He found it impossible to breathe when lying flat. Large multiple bilateral cervical tumors were present.

X-ray examination of the chest showed that the trachea at the level of the thoracic outlet was compressed by the tumor and that on the left side the tumor descended well below the arch of the aorta. The superficial veins of the neck and chest were dilated.

At operation, eleven large separate lateral aberrant thyroid tumors were removed from the right side of the neck (fig. 1). The jugular vein was enormously dilated and adherent to the tumors, which surrounded it on three sides. It was necessary to remove the vein with the tumor mass. The carotid artery and vagus nerve were carefully dissected away from the tumors and were preserved intact.

From the time of operation until the patient's death, five hours later, bradycardia and Cheyne-Stokes respiration were present. Consciousness was never regained. Postmortem examination showed that the left jugular and subclavian veins were completely obliterated by large tumor masses, which extended into the mediastinum to a point well below the base

of the heart. Apparently all venous return from the left side of the neck had been blocked by these tumors. On the right the resection of the internal jugular vein and ligation of the external jugular vein had resulted in interference with the circulatory return from the brain, and death was caused by cerebral congestion and anoxemia.

This case is of particular interest because it is the only one in this series in which death resulted from lateral aberrant thyroid tumors. It indicates that, although these tumors do not metastasize, they may slowly and progressively enlarge and may ultimately become inoperable and cause death by pressure. For this reason patients with lateral aberrant thyroid tumors should be operated on while the tumors are still small and can be easily removed.

SUMMARY OF SEVENTEEN CASES

Incidence.—In the past fifteen years, seventeen tumors of lateral aberrant thyroid origin have been recognized at the Cleveland Clinic. Nine of the seventeen patients have been operated on in the past two years.

Fig. 1 (case 3).—Gross specimen of multiple lateral aberrant thyroid tumors.

Age.—The age of the patients varied from 10 to 57 years, the average age being 36. Thirty-five per cent of the patients were between 20 and 30.

Sex.—Tumors arising in lateral aberrant thyroid tissue are more common in women than in men, the ratio being 13 to 4 in this series.

Race.—Eight of the seventeen patients in this series were of Jewish extraction.

Symptoms.—A painless lump which either enlarged very slowly or not at all was the most common symptom. Eighteen per cent of the patients had not noticed the tumor and it was discovered only during examination or operation for a goiter. In only 12 per cent was the mass either painful or tender. Twelve per cent had severe symptoms of pressure.

Examination.—The lumps were usually described as firm and were generally considered to be lymph nodes. The extensiveness of the distribution of the nodules was rarely apparent from external examination, their location deep beneath the sternomastoid muscle rendering them very difficult to palpate. In the cases of multiple tumors in which the thyroid was similarly involved, the affected lobe was hard and suggested the presence of either thyroiditis or a malignant process.

Distribution of Nodules.—The lateral aberrant thyroid tissue was found in all triangles of the neck. In six cases the nodules were on the left and in six cases on the right; in the remaining five cases they were bilateral. It should be noted that, in all the nine cases in which more than six lateral aberrant thyroid nodules were present, one lobe of the thyroid was involved in a similar pathologic process. In five of these nine cases the tumors were present in the superior mediastinum. The nodules were also found posterior to the trachea and posterior to the carotid sheath.

Number of Nodules.—The number of nodules present varied from one to twenty-five, averaging seven. In nine cases there were six or more separate tumors. In the case in which twenty-five nodules were present, the actual count could be increased to thirty or more by separating tumors which were adherent to one another but were removed in a single mass.

Thyroid Gland.—One of the seventeen patients had an adenomatous goiter without hyperthyroidism and one had an adenomatous goiter with hyperthyroidism. In eleven cases it was found that the same pathologic process was going on in the thyroid as in the lateral aberrant tissue.

There was a benign papillary adenoma in three cases, a papillary carcinoma in five cases, a malignant adenoma (no papillary structure) in one case and a hard nodule palpable in the thyroid (patient refused operation) in two cases.

In only four cases was the thyroid normal. In the cases classified as instances of papillary carcinomas, the tumors were low grade malignant growths difficult to differentiate from benign tumors (fig. 2).

Histologic Aspects of Lateral Aberrant Thyroid Tissue.—In eleven cases the lateral cervical nodules were benign papillary adenomas, in five cases the tumors were papillary carcinomas and in one case they were malignant adenomas with no papillary structure present. In this case veins were invaded by tumor tissue and each of the seventeen tumors was apparently an independent

malignant adenoma with a structure similar to that of the malignant adenoma in the lobe of the thyroid. A determination of the iodine content done on lateral aberrant thyroid tissue classified as papillary adenoma showed 3.41 micrograms of iodine per hundred milligrams of tissue.

Diagnosis.—In six of the seventeen cases the correct diagnosis was made before operation, and in two additional cases the diagnosis of lateral aberrant thyroid was considered but other diagnoses were preferred. In all the cases in which the correct diagnosis was made, the lobe of the thyroid on the affected side was involved.

The distribution and consistency of the nodules usually suggest that they are lymph nodes. The pre-operative diagnoses in the seventeen cases were lateral aberrant thyroid in six, metastatic carcinoma of the thyroid (? lateral aberrant thyroid) in one, tuberculous glands (? lateral aberrant thyroid) in one, tuberculous glands in three, branchial cleft cyst in two, nodules unsuspected until operation (thyroidectomy) in two, lymphoma in one and abscess in one.

At operation the nodules are usually recognized as lateral aberrant thyroid tissue. When cystic there is a

characteristic bluish discoloration similar to that of a cystic adenoma of the thyroid. When solid they are reddish and resemble thyroid tissue.

The vascularity of the tumors and the presence of large blood vessels in their capsules differentiate them from lymph nodes. In some cases the tumors are adherent to one another and to surrounding structures. They are characteristically surrounded by thick, hyaline, fibrous or fatty capsules, the gross appearance of which serves to differentiate them from lymph nodes. It is the gross rather than the microscopic appearances that establish the diagnosis and rule out the possibility of metastatic carcinoma.

The most important distinguishing feature of these lateral cervical tumors is their association in over half of the cases with a hard tumor in the thyroid gland. The finding of a hard thyroid tumor and one or more firm lateral cervical nodules is sufficient evidence on which to base a diagnosis of lateral aberrant thyroid tumor.

End Results.—One of the seventeen patients in this series has not been heard from since operation, one has just been operated on and a third died after operation. None of the remaining fourteen patients, all of whom have been followed for periods varying from six months to thirteen years (an average of nearly four years), have died as a result of thyroid disease or lateral aberrant thyroid tumors, and at the present time no patient is known to be suffering any disability as a result of recurrence. Only two patients received high voltage roentgen therapy after operation.

To date, six of the seventeen patients have had a recurrence. Two of the patients with a recurrence have refused operation, but with the other patients the disease has been controlled by a second operation. The patients in whom the tumors recurred were operated on in the days before we appreciated the wide distribution of the nodules or the necessity of careful and extensive exploration of the neck. The recurrent tumors did not represent true recurrences of tumors removed but were primary tumors which had been overlooked at the time of the first operation.

Roentgen Therapy.—Five of the seventeen patients in this series received roentgen therapy before operation. In none was there any appreciable diminution in the size of the nodules, nor did the treatment induce any evidences of degeneration of the tumor.

Tumors arising in lateral aberrant thyroid tissue grow slowly and are well differentiated. Since permanent cure has been effected in all patients subjected to surgical intervention alone, there is no indication for adding roentgen therapy to operation in the treatment of lateral aberrant thyroid tumors that have been cleanly excised.

CONCLUSIONS

Papillary tumors of the thyroid, whether found in the thyroid proper or in the lateral cervical region, are remarkably benign and do not tend to metastasize. Local recurrence may take place if the tumors are incompletely removed or if the presence of additional tumors is overlooked at the time of operation.

Roentgen therapy has not been effective in arresting the growth of these tumors. Reliance must therefore be placed on their complete excision by surgical means.

In every case in which a papillary tumor is found in the thyroid, careful exploration of the neck for similar tumors of lateral aberrant thyroid origin should be undertaken. Similarly, when a lateral aberrant

thyroid tumor is found, the thyroid gland should always be explored to rule out the presence of a coexistent papillary tumor.

It is probable that many cases reported in the literature as instances of papillary carcinoma of the thyroid with metastasis to the cervical lymph nodes are in reality instances of benign papillary adenoma of the thyroid with multiple primary aberrant thyroid tumors coincidentally present in the lateral cervical region. What may at first appear to be a hopelessly inoperable carcinoma with extensive metastasis may be cured by a persistent surgical attack.

SUMMARY

1. It may be difficult both clinically and pathologically to distinguish between multiple primary lateral aberrant thyroid tumors and metastases from a papillary carcinoma of the thyroid.

Fig. 2.—Typical benign papillary adenoma of the thyroid from a patient with multiple lateral aberrant thyroid nodules.

2. Papillary carcinomas of the thyroid have not, in my experience, metastasized to the cervical lymph nodes.

3. In eight of seventeen cases of lateral aberrant thyroid tumors, tumors histologically identical with the lateral cervical nodules were present in the thyroid gland.

4. It has not been proved that either distant or local metastasis occurs from papillary tumors of lateral aberrant thyroid origin.

5. It is probable that many cases reported as instances of papillary carcinoma of the thyroid with metastasis to the regional lymph nodes are in reality instances of benign papillary lateral aberrant thyroid tumors with a coexistent benign tumor in the thyroid gland.

6. Irradiation has not been effective in the treatment of lateral aberrant thyroid tumors. Surgical intervention is the treatment of choice for all papillary tumors of thyroid or lateral aberrant thyroid origin.

INTRATHORACIC GOITER

FRANK H. LAHEY, M.D.

BOSTON

In spite of the fact that many authors have repeatedly written about the dangers of permitting adenomatous goiters to become intrathoracic, the likelihood and dangers of this occurrence are still not sufficiently appreciated. Failure to remove an adenomatous goiter which is extending beneath the clavicles and sternum before it has become deeply intrathoracic constantly results in the patient's being exposed to the necessity of submitting himself to a procedure involving a dissection deep in the mediastinum, to the dangers and mechanical difficulties of extracting a large adenomatous tumor from deep in the superior mediastinum and to the often perplexing problem of making a mediastinal tumor twice the diameter of the superior thoracic strait pass through that aperture in its surgical delivery.

The most common type of goiter which becomes intrathoracic is the discrete adenoma originating as a small single adenoma in the lower pole of the thyroid and gradually descending beneath the sternum and clavicle until it is no longer located in the neck but has so descended that it is now within the thoracic cage itself. In writing on this subject previously I have called attention to the fact that, once the discrete adenoma becomes located within the thoracic cage and enlarges

of the central portion of an adenoma until its solid portion is replaced by fluid retained by the fibrous capsule of the adenoma. The fact that but a limited number of such intrathoracic thyroid cysts have been seen at the Lahey clinic leads my associates and me to believe that this is not a common type of intrathoracic goiter.

Next to discrete adenomas, multiple colloid adenomatous goiters, particularly of the endemic variety, have, according to our experience, been most prone to become

Fig. 2.—Typical deviation of the trachea from a laterally placed adenomatous goiter wedged in the upper thoracic aperture, with tracheal narrowing. Note the caliber of the trachea at the upper arrow and the narrowed trachea at the lower arrow.

Fig. 1.—Enormous intrathoracic goiter. Obviously this can be removed without taking off the clavicles and the manubrium only by collapsing its center and so diminishing its diameter. Note the sharpness of outline typical of the intrathoracic discrete adenoma.

in diameter, the outflaring of the upper portion of the thoracic cage necessitates further and further descent of the spherical mass as its diameter increases. Occasionally there will occur intrathoracic cysts of the thyroid, since thyroid cysts are brought about by liquefaction

intrathoracic. Most multiple colloid adenomatous goiters tend to enlarge upward and outward on the neck, producing large and unsightly goiters. This is due to the fact that the enlargement of the thyroid in this form of thyroid degeneration is general throughout the entire thyroid gland and not local, as is the case with discrete adenomas. In our fairly large experience with intrathoracic goiter there have been a considerable number of multiple colloid adenomatous goiters which have become deeply intrathoracic.

THE MECHANISM OF THE DESCENT OF INTRATHORACIC GOITER INTO THE MEDIASTINUM

When an adenoma occurs in the thyroid, particularly in the isthmus or the lower pole of the gland, all the factors are present for propelling that tumor into the superior mediastinum. The adenoma rests above an unobstructed superior thoracic strait bounded on the front by the clavicles and the sternum and on the sides and back by the vertebrae and the first rib. Any discrete tumor arising in the lower pole of the thyroid gland, covered as it is by the sternohyoid, sternothyroid and omohyoid muscles, which limit upward extension by their attachments to the hyoid and thyroid cartilage and which are inserted into the chest wall in front, is subjected to pressure in the downward direction with every act of swallowing.

UNDESIRABLE EFFECTS OF INTRATHORACIC GOITER

The dangerous effects of intrathoracic goiter are the result of pressure from the adenomatous goiter on the

From the Department of Surgery, the Lahey Clinic.
Owing to lack of space, this article has been abbreviated in THE JOURNAL. The complete article appears in the author's reprints.
Read before the Section on Surgery, General and Abdominal, at the Ninetieth Annual Session of the American Medical Association, St. Louis, May 19, 1939.

side walls of the trachea, producing lateral deviation and lateral narrowing of that structure (fig. 2). When bilateral adenomas of the thyroid descend into the mediastinum, the effects on the trachea are the result of bilateral pressure as the tumors impinge on the lateral walls of the upper thoracic strait, particularly the right and left first rib, resulting in bilateral pressure and lateral collapse of the trachea. This produces the so-called scabbard trachea as shown in figure 3. When the adenoma arises in the isthmus and descends behind the sternum, anteroposterior pressure is exerted on that structure and anteroposterior collapse of the trachea occurs (fig. 4).

The other undesirable effect of intrathoracic goiter is on the cerebral venous circulation. When an intrathoracic goiter passes through the upper thoracic aperture it exerts marked pressure on the large internal jugular veins, thus interfering with the return of venous blood from the head and neck. We have demonstrated conclusively from readings of the venous pressure before and after the removal of intrathoracic goiters that there

Fig. 3.—Bilateral pressure on the trachea producing bilateral narrowing at the point indicated by the arrows.

is a distinct rise in venous pressure in the veins above the intrathoracic goiter and that this promptly drops with the removal of the intrathoracic mass. This in itself perhaps produces no great difficulty, but it seems at least possible that the rapid change in cerebral venous pressure which results from the sudden removal of the obstructing mass when the intrathoracic goiter is rapidly delivered may be an undesirable factor, possibly playing some part in the mortality attached to the removal of large and deep intrathoracic adenomas.

SYMPTOMS OF INTRATHORACIC GOITER

The symptoms of intrathoracic goiter are directly related to the foregoing facts. Associated with the narrow trachea caused by anteroposterior, bilateral or lateral pressure on the trachea is an interference with free breathing. This obstruction to respiration may evidence itself with the head held in any position by noisy and stridulous breathing, particularly on exertion, when there is an unusual demand for air. When there is anteroposterior collapse of the trachea due to an adenoma arising in the isthmus, it may evidence itself only as the patient bends over and thus crowds the

medially located adenoma further against the trachea and produces further tracheal collapse. It may evidence itself when the adenoma deviates the trachea to one side, producing lateral collapse only when the head is tilted to one side, thus causing the adenoma to impinge on the right or left first rib to serve as a fulcrum and make additional lateral pressure on the already partially collapsed trachea.

The effects of pressure from an intrathoracic goiter partly obstructing the return of venous supply from the head and neck by pressure on the internal jugular veins evidence themselves by the dilatation of the superficial veins of the upper part of the chest and neck, compensatorily enlarged to take care of the return venous supply from the head (fig. 5). When the obstruction to the internal

Fig. 4.—Anteroposterior collapse of the trachea from an adenoma arising in the isthmus and wedged behind the sternum. Note the caliber of the trachea above and the narrowness of the trachea at the point where it enters the thoracic cavity.

Fig. 5.—A, an infra-red photograph showing the normal superficial thoracic veins. B, an infra-red photograph showing the dilatation of the superficial thoracic veins in a patient with intrathoracic goiter. Even in this photograph one can appreciate the moderate edema of the neck and lower portion of the face.

jugular veins is fairly complete, this may even evidence itself by edema of the face, as revealed by the putty-like features secondary to the facial edema shown in figure 6.

THE DIAGNOSIS OF INTRATHORACIC GOITER

Whenever, particularly in a patient with adenomatous goiter, it is impossible to palpate definitely the lower pole of the thyroid as the patient swallows, when with the act of swallowing the enlarged thyroid can still be felt to extend below the point of the palpating finger,

Fig. 6.—Putty-like features associated with edema due to pressure on the internal jugular vein from an intrathoracic goiter.

one should be suspicious that the goiter is already intrathoracic or is definitely becoming so. When an intrathoracic goiter has become definitely located within the superior mediastinum, particularly when it is on one side of the trachea, it is usually possible to detect

Fig. 7.—The typical tongue of intrathoracic goiter extending from the lower pole of the thyroid into the thorax beside the trachea, not producing the spherical outline seen in figure 1. It is such tongues of intrathoracic adenomatous tissue that are sometimes overlooked if not demonstrated by x-ray examination.

dulness on percussion in the upper part of the chest over the tumor. When a discrete adenoma located in a lobe of the thyroid has descended into the mediastinum and has produced marked deviation of the trachea, it is frequently possible by palpation of the trachea to

demonstrate that that structure has been markedly distorted to a lateral location well outside its normal median position. The diagnosis of intrathoracic goiter can be definitely established by roentgenograms, for roentgenograms demonstrate the extension of the shadow of the thyroid into the mediastinum with or without lateral deviation of the trachea by the intrathoracic mass or anteroposterior collapse.

If one thing has been impressed on our minds in dealing with a large number of patients having intrathoracic goiter, it has been the ease with which such goiters can be overlooked in the course of routine examination. So frequently do tongues of multiple adenomatous goiters extend into the mediastinum beside or behind the trachea without evidence of tracheal pressure, without respiratory obstruction and without pressure on the internal jugular vein, that we have for several years made it a custom to make roentgenograms of the superior mediastinum of all patients with multiple colloid adenomatous goiter. This we know to be

Fig. 8.—A tongue of intrathoracic goiter extending into the chest beside the trachea.

extremely important, lest such extension of thyroid adenomatous tissue into the mediastinum be overlooked and at operation the anterior portion of the thyroid only be removed and its posterior shell of thyroid tissue, together with its intrathoracic prolongation, be unrecognized and left behind, only later to enlarge and require further surgical procedures.

ANESTHESIA IN OPERATIONS FOR INTRATHORACIC GOITER

In our earlier experiences with deep intrathoracic goiters we, to say nothing of the patients, had some hair-raising experiences in attempting to get enough air and anesthetic mixture into the patient while the untubed trachea was collapsed by the pressure of the intrathoracic mass as it was being delivered through the superior thoracic strait. With the introduction of the rigid intratracheal catheter this difficulty has now been entirely obviated. As a result of our experience in such cases we feel that no intrathoracic goiter of any considerable depth in the mediastinum should be removed without first introducing a rigid walled catheter

into the trachea. This makes it certain that both air and anesthetic mixture can be supplied to the patient no matter how vigorous the manipulations may be in the extraction of the intrathoracic tumor.

One of the greatest aids which we have developed in the anesthetic management of patients with intrathoracic goiter has been the employment of helium mixed with oxygen and cyclopropane. This has permitted us to get the patient with a deep intrathoracic goiter and narrowed trachea sufficiently anesthetized and relaxed so that an intratracheal catheter could be readily introduced through the cords even when under direct laryngoscopic vision the larynx and trachea were markedly distorted. This was one of the unsatisfactory problems with which we had to deal before our anesthesiologists applied helium, oxygen and cyclopropane to overcome the difficulty. When the trachea was markedly narrowed by an intrathoracic mass and the anesthetic was administered, because of spasm, mucus and induction difficulties it was often almost impossible to anesthetize the patient so that relaxation could be obtained to a sufficient degree to make possible exposure of the larynx through the laryngoscope and the introduction

Fig. 9.—This patient with an intrathoracic goiter had previously had her manubrium removed, together with the inner aspects of her clavicles, and had been rejected as having an inoperable mass. The adenoma was later removed without difficulty by collapsing its center; it could have been taken out originally without removing the manubrium and clavicles had this procedure been followed.

of the rigid catheter through the cords. By the use of helium, oxygen and cyclopropane this difficulty has now been largely overcome. Since helium has such a low molecular weight—the molecular weight is 4, compared with the molecular weight of 32 for oxygen—it can be so mixed with oxygen that it serves the purpose of thinning oxygen, as kerosene will thin cylinder oil, and thus make it possible to introduce greater quantities of oxygen through a smaller aperture. Fortunately, helium in itself is metabolically inert and can therefore be used purely as a diluting mixture. By the employment of 80 per cent helium mixed with 20 per cent oxygen, three times as much oxygen can be passed through an aperture of given size as will pass through when pure oxygen is introduced undiluted. The use of this mixture has been a valuable measure, therefore, in producing the depth of anesthesia necessary for the relaxation required to introduce the intratracheal catheter.

Two types of intratracheal tubes are employed in the production of intratracheal anesthesia: (1) the flexible metal walled catheter and (2) the rubber (Magill) catheter.

As the result of a large experience with intrathoracic goiter before the days of tracheal intubation and further

Fig. 10.—An enormous intrathoracic goiter, demonstrating the depth to which such goiters can extend.

experience with this condition after the development of intratracheal catheters, it is our opinion that when there is the slightest question of deviation of the trachea or extension of the goiter into the mediastinum an intratracheal catheter should be introduced. While it is possible to introduce an intratracheal catheter in the midst of the operation, it is an undesirable manipulation to have to undertake at this time. Its preoperative introduction requires but a few moments effort, and it is distinctly desirable in all cases of doubtful involvement to have the intratracheal catheter already in place before the operation is undertaken.

SURGICAL REMOVAL OF INTRATHO- RACIC GOITER

The most important single feature relating to the surgical removal of deep intrathoracic extensions of thyroid tissue is the control of their blood supply before their surgical manipulation within the mediastinum is undertaken. Since the separation of the intrathoracic mass from its surrounding condensed connective tissue and pleura must be accomplished by finger manipulation within the mediastinum, it is undesirable and unnecessary that hemorrhage occur at this time, the blood supply can be so well controlled. The blood supply to an intrathoracic goiter comes

Fig. 11.—A deep intrathoracic goiter which had extended partly behind the trachea and had narrowed that structure; it was successfully removed.

entirely from above, from the superior and the inferior thyroid arteries. The venous supply is largely from branches from the thyroid to the internal jugular vein. It is possible to demonstrate and ligate both the superior and the inferior thyroid arteries in all cases before any attempt is made toward removal of the intrathoracic mass.

Fig. 12.—An enormous multiple colloid adenomatous goiter, with calcified shells, deep within the mediastinum.

It is likewise possible to ligate all the venous connections between the thyroid and the internal jugular vein before any approach is made to the intrathoracic goiter. The first step, then, of the removal of any deep intrathoracic goiter is that the superior and inferior thyroid arteries be demonstrated and doubly ligated and the vessels cut between ligatures. All the veins running from the thyroid to the internal jugular vein are doubly ligated and

cut between ligatures, thus making the intrathoracic mass largely free within the mediastinum without an attached blood supply. The removal then represents merely the freeing of the intrathoracic mass digitally from the surrounding condensed mediastinal tissue and

Fig. 13.—An intrathoracic goiter showing the extension of masses arising from the lower poles of the thyroid on each side, removed from the mediastinum.

pleura and the mechanical delivery of the tumor through the upper thoracic aperture.

Practically all intrathoracic goiters have definite capsules with semisoft centers, even though they are of the multiple colloid adenomatous variety of goiter. Exclusive of those intrathoracic goiters which are solid because they have acquired malignant characteristics of

the carcinomatous variety, practically all intrathoracic goiters are amenable to being broken down in their centers. We have seen more than one patient who has had the inner half of the clavicles and the upper end of the sternum removed before coming to us, the operation having been given up because the intrathoracic mass was considered to be too large to be removable. In an experience now represented by approximately 700 operations for intrathoracic goiter, we have but three times found it necessary to remove the sternum in order to remove the intrathoracic mass. This number (700) includes only operations for goiters which have descended to or below the arch of the aorta. Roentgenograms (figs. 10, 11 and 12) and photographs (figs. 13, 14, 15 and 16) are shown of enormous intrathoracic goiters extending downward almost to the diaphragm which have been successfully removed without taking off the front wall of the chest. It is obviously impossible to deliver an intrathoracic goiter such as that

Fig. 14.—An intrathoracic goiter showing the spherical shape of a discrete adenoma removed from within the mediastinum.

shown in figure 1 through the upper thoracic strait, since its diameter in all directions is considerably greater than the diameter of this strait. Such a tumor could be removed only by increasing the diameter of the upper thoracic strait or by decreasing the diameter of the tumor. The procedure which we for several years have employed is one aimed at decreasing the size of the intrathoracic mass. Practically all intrathoracic goiters, once the prethyroid muscles are cut and turned down, are palpable at the upper end of the mass. A double hook of the type which we have modified for thyroid operations (fig. 17) is inserted into the upper end of the intrathoracic tumor. Another double hook is placed opposite this, and the upper end of the intrathoracic mass is then pulled well up into the superior thoracic strait. With a knife a slit is then made through the capsule in the top of the tumor. A finger is inserted into the center of the tumor and twirled about until the center is broken down. This can be done with but little bleeding, since the arterial and venous blood supply has

been controlled. This partial collapse permits further elevation of the tumor into the superior thoracic strait. More of the central portion of the tumor is then broken down with the finger, thus permitting further delivery of the tumor into the upper thoracic strait. Further separation of the surrounding condensed mediastinal connective tissue and the pleura is carried out digitally until the tumor is entirely delivered.

Great care must be taken as the tumor is delivered from the mediastinum to free it carefully by digital manipulation from the pleura and the surrounding mediastinal tissue. This is easily done in most instances. There will, however, be occasional cases in which, as a result of inflammatory reaction, there will be dense adhesions between the pleura and the capsule of the adenoma. These must be carefully separated, and occasionally it is necessary, when a dense local area of

is certain to fill up with fluid and blood if unpacked, thus exposing the patient unnecessarily to the danger of infection and secondary mediastinitis.

We have frequently stated that one of the most important considerations after thyroid operations is when to do a tracheotomy, and we have condensed our

Fig. 15.—One lobe of the thyroid together with the intrathoracic mass successfully removed from the mediastinum. Note how impossible it would be to palpate the lower pole of this lobe, and note the spherical outline of the intrathoracic adenoma.

inflammatory reaction has occurred between the pleura and the capsule, to leave a small segment of the capsule attached to the pleura. It is infinitely better to leave attached to the pleura a small segment of the capsule of a very adherent adenoma than to risk the rupture of the attached pleura. One must be extremely careful in the removal of a deep intrathoracic mass not to break the tumor up but to remove it as a complete mass. If segments of the unvascularized tumor are left behind they may well slough and result in secondary infection and mediastinitis. One should also be extremely careful after the mediastinal mass has been removed to inspect the cavity with the direct vision light to make sure that there do not remain bleeding plexuses of veins on the attached pleura.

After the removal of a large intrathoracic thyroid mass, a large loose pack of gauze completely filling the cavity should be introduced and should remain within the cavity for a minimum of seven days. The cavity

Fig. 16.—Prolongation of a multiple colloid intrathoracic goiter into the mediastinum. Note that multiple colloid adenomatous goiters becoming intrathoracic are less spherical than are discrete adenomas.

experience with this problem into the statement that, when one begins to wonder whether or not tracheotomy should be done, that is the time to do it for a patient having breathing difficulties after a thyroid operation. Provided the tracheotomy is done low enough in the trachea and provided the mediastinum has been well packed with gauze, there is little disadvantage to a tracheotomy at this time. As soon as the tube is removed the trachea will close and, provided the packing has been adequate, there will be but little danger of mediastinitis. After all, should there be sufficient interference with breathing one must accept the risk of mediastinal contamination with a tracheotomy or the risk of suffocation.

Fig. 17.—The double hook employed in the Lahey Clinic for grasping the thyroid. Note that when the jaws are closed, since they are flat, they serve as hemostats to control bleeding.

It has been our experience that after the removal of the intrathoracic masses the deviated and collapsed trachea soon resumes its normal caliber and its median position.

In the entire series of cases of intrathoracic goiter, including all types, the very deep, which have extended

nearly to the diaphragm, the malignant growths and those for which the anterior wall of the chest was removed, the mortality to July 1933 was 4.4 per cent; from July 1933 to the present time the mortality has been decreased to 1.7 per cent. It must be accepted when intrathoracic goiters have been permitted to extend so deeply into the chest that they are very close to the diaphragm and that the mortality will be higher than for operations for extrathoracic goiters, which again brings me to the point mentioned in the introduction to this paper. While the problem of the management of the intrathoracic goiter deals with its successful mechanical removal from the mediastinum, the really successful approach is through the prompt removal of all adenomas of the thyroid and adenomatous goiters that are becoming or tending to become intrathoracic.

SUMMARY

The types of goiter which become intrathoracic are discrete adenomas, cysts of the thyroid and multiple adenomatous goiters.

The mechanism of the descent of a goiter through the superior thoracic strait is related to the anatomy of the upper thoracic aperture.

The undesirable effects of intrathoracic goiter are the results of pressure on the trachea and the internal jugular veins.

The symptoms of intrathoracic goiter are largely related to these three factors.

The introduction of a rigid intratracheal tube before operation for intrathoracic goiter is necessary.

Large intrathoracic goiters can be extracted from the mediastinum without removing the chest wall if the proper procedure is followed.

ABSTRACT OF DISCUSSION

ON PAPERS OF DRS. FOSS, HUNT AND McMILLAN,
DR. CRILE AND DR. LAHEY

DR. FREDERICK A. COLLIER, Ann Arbor, Mich.: A great deal of attention has been devoted to the crisis that occurs after operation. There is a group of patients who have thyroid crises for whom something can be done, and that is the group that have their crisis before they reach the surgeon. In 1934 Ransom and Bayley analyzed the proved cases of thyroid crisis that had occurred in the medical and surgical wards of University Hospital, Ann Arbor. There was a definite group of patients that went into crisis because they came for treatment too late. Instead of compound solution of iodine, inadequate sedation was given to them. There was a group on whom we were unwise enough to operate for lesions other than the goiter. These were operations carried out on patients with minor degrees of hyperthyroidism that precipitated a crisis. We should not carry out any type of operation on patients with even mild degrees of hyperthyroidism unless those operations are designed to relieve the hyperthyroidism. Another group of patients developed crisis following infections of only moderate severity, such as tonsillitis, pyelitis, cholecystitis or thrombophlebitis. Another group of patients had a thyroid crisis precipitated by therapeutic and diagnostic procedures, such as thoracentesis, abdominal paracentesis, lumbar puncture or basal metabolic determinations; that is, these tests were carried on too soon after the patient got into the hospital. There was a last group of patients developing crisis who had inadequate sedation. They had had inadequate sleep or no sleep for eight successive nights. They had all been given sedatives of the usual type but no attention had been paid to the fact that these sedatives had not been effective. We do not know the cause of crisis but we can often prevent it by regarding hyperthyroidism

of even a moderate degree as a severe disease that should have definitive treatment just as soon as we can make the diagnosis.

DR. JAMES H. MEANS, Boston: Thyroid storms are not necessarily postoperative. Other stimuli than operation can produce this peculiar and alarming reaction which thyrotoxic patients exhibit. Plummer claimed that a tendency to develop the type of reaction which we call storm or crisis is really one of the fundamental characteristics of exophthalmic goiter. He was accustomed to speak of "crisis status," a phase of the disease in which the patient at any moment was likely to be thrown into storm. Plummer's introduction of iodine in the routine care of persons with exophthalmic goiter has almost, but not quite, abolished this alarming complication. The etiology or the mechanism of storm is really unknown. We may say that a storm represents an acute failure of what Cannon has called homeostasis, the cause of the failure being excessive stress of any sort. Whether the stress is anoxemia, too much self-administered epinephrine, infection, or on the part of the patient, its effects can be looked on as a failure in the ability of the body to maintain an equilibrium in the face of a thoroughly pathologic metabolic setup. The crisis is characterized by an intensification of thyrotoxicosis, but probably more than any other one thing it is characterized by a very fulminating hyperthermia. I have lately become interested in observing the psychologic state of patients with toxic goiter. I agree with Dr. Collier that proper sedation should be employed. It is equally important that oversedation should not be allowed. You have to hit a happy medium. The best sedation for most of these patients is iodine. The remarkable thing is that iodine has a most astonishing effect on nearly every function of the body, including the emotional state, which characteristically becomes calmer. But if on iodine this doesn't happen, the patient bears watching. These are the ones who are likely to have a storm. Treatment of storm must be prompt, rapid and vigorous and includes oxygen, fluid and dextrose, and iodine. Actually during crisis a minimum of sedation should be used. But most important is a vigorous treatment of the hyperthermia. Persons with hyperthermia have to be packed in ice or bathed in ice water; cold packs or spongings merely are not enough.

DR. JAMES D. RIVES, New Orleans: I should like to add one to the numerous known causes of thyroid crisis so well described by Bayley. The human being is capable of adaptation to a tremendously wide variation in external temperature. Gessler has demonstrated that heat production is high in cold weather and low in warm weather. Eaton has demonstrated that the basal metabolism in subtropical countries is about 10 per cent lower than the usual standards. The hyperthyroid patient obviously cannot make this response to variation in external temperature. His salvation lies in an increase of heat elimination rather than a decrease in heat production. Rubner has shown in the dog that, as external temperatures increase, heat loss by evaporation increases from about 25 per cent at 70 F. to about 75 per cent at 95 F. The dog sweats only on his footpads and it is probable that in the human being, as stated by Du Bois, heat loss is almost entirely by evaporation when the external temperature reaches 95 F. New Orleans is an ideal place in which to show the effects of heat and humidity in the causation of thyroid crisis. The records of the local weather bureau show that the temperature from the first of May until the middle of October is consistently so high that a majority of heat elimination must take place by evaporation. They also show that the humidity is constantly so high that heat loss by evaporation is minimal. Obviously, this causes serious embarrassment of the heat regulating mechanism. I have collected cases of nonsurgical thyroid crisis in the Charity Hospital for a period of nine years, from 1930 to 1938. I found twenty-one cases of nonsurgical or spontaneous thyroid crisis, sixteen of these occurring in the five months from June to October inclusive. The incidence is greatest in the latter part of this period, owing, I believe, to the long continued exposure to high temperatures and humidities during the preceding months. It seems to me probable that, in countries where the temperatures are high but the humidities low, no serious harm would result. I do not intend to convey the idea that this is the only, or even the most important, cause of thyroid crisis, but I do believe that it is definitely a contributory factor.

DR. WILLARD BARTLETT JR., St. Louis: The point of view which says that the postoperative crisis, or the degree of postoperative reaction in general, develops in proportion to the amount of thyroid tissue left in the neck at the time of operation is wholly contrary to all experience. I know of no respectable weight of evidence for this point of view, but it seems to have achieved a certain amount of fashion. It is a highly dangerous point of view and if persisted in leads to numerous avoidable tragedies. It violates the principle that the degree of reaction is dependent on the amount of work done on the patient in any given situation in comparison with his ability to withstand whatever that planned procedure is. Please understand me, I am not decrying total thyroidectomy as a means of diminishing recurrence of hyperthyroidism but rather the performance of total thyroidectomy as a hopeful procedure in diminishing the severity of postoperative reactions. It should be clearly understood that the operative risk nowadays can be measured with mathematical accuracy and, as Dr. Collier's experience has shown in recent years, there have been considerably more deaths in crisis in patients preceding operation than after operation. So also we, since 1930, have had nearly three times as many deaths in thyroid crisis occurring in patients who were not operated on at all, but in whom crisis came on within a few hours to a few days of admission to the hospital, as we have had postoperatively.

DR. HAROLD L. FOSS, Danville, Pa.: Dr. Means refers to the importance of the patient's psychic state. While the mental condition of the patient with active hyperthyroidism must be closely observed and treated, the patient does not die from a mental disturbance alone. Crisis depends on something far more tangible and, one might say, more organic. We who work in large thyroid clinics have all observed the obvious nervousness which is so cardinal a part of the syndrome of exophthalmic goiter, yet, once the confidence of the patient is secured, he is usually found to be a person of rather unusual fortitude. While excessively nervous he is yet not "neurotic" and is usually clamorous for relief and faces the operation with unusual courage. While the psychic phases of the problem are important, that unknown something occurring within the organism in which disturbances of thyroid physiology plays the major role is one of the riddles of modern medicine. The increase in metabolism must be tremendous. No one has ever accurately determined it. The hyperorexia, uncontrollable delirium and uncountable pulse are all part of the picture, the exciting factor of which is yet unexplained. Postoperative crisis in classic exophthalmic goiter is now rare. It was common twenty years ago and accounted for many deaths. We worry but little today over the possibility of impending postoperative storm in the young woman with typical exophthalmic goiter of but a few months duration. Such states are readily controllable today, yet the same condition caused great concern a generation ago. We have today under consideration the patient past 60 with associated arteriosclerosis, cardiovascular and other visceral degenerative changes incident to advancing years and who gives a history of having had a goiter "since a girl" or for "many years," the patient who has frequently had interminable iodine medication or has been subjected to various forms of bizarre, therapeutic vagaries in an attempt to relieve her of her "heart disease" or whatnot without the true nature of the situation being understood. These are the patients who, years after the appearance of a goiter, develop, insidiously, symptoms of hyperthyroidism and who, within thirty-six hours following operation, suddenly and unexpectedly plunge into a state of crisis from which many never recover. Oddly enough, nothing is found on postmortem examination other than myocardiovascular changes incident to senility to account for the rapidly advancing crisis. Dr. Rives's ingenious meteorological explanation for crisis is interesting. I feel, however, that the patient who is to develop postoperative thyroid crisis, everything else being equal, will about as readily have it in the arctic as he will in the tropics. There is no more unexplained phenomenon than hyperthyroid crisis and the curious thing is after years of intensive study of the thyroid and the thousands of postmortem examinations, so little has been contributed to the exact knowledge of its mechanism.

TRAUMATIC EPIDIDYMO-ORCHITIS

GEORGE H. EWELL, M.D.

MADISON, WIS.

Owing to the mobility of the testicles, as well as to their adequate scrotal coverings and their location between the fleshy parts of the thighs, injury to them is relatively infrequent. That many persons receive injuries for which they do not seek medical aid is no doubt true.

Several cases of traumatic epididymo-orchitis have come under my observation. Most of the patients were young adults, the youngest a boy of 12. Several varieties of trauma were involved, baseball injuries being the most common. Injuries from wrestling and from striking the handles of lawn mowers were observed. For the most part, the injuries I have seen have been of no unusual moment. None required any type of surgical intervention. I have been able to observe only a few patients at periods after the injury; in none did atrophy of the testicle occur. However, this complication is not uncommon after such injuries.

I observed one instance of laceration of the scrotum in which the testicle was hanging outside the scrotum when the patient was admitted. No complications followed surgical closure of the wounds.

Wesson¹ observed that college athletes seldom have traumatic orchitis but occasionally suffer from epididymitis caused by infection. A medical colleague, Dr. Walter Meanwell, a basketball coach and athletic director of many years' experience, informs me that such injuries seldom occur in the larger schools during intercollegiate contests, owing, in his opinion, to the fact that the athletes are provided with adequate protection (some type of heavy suspensory). But in intramural and interfraternity athletics, for which this protection is not provided, he has observed several such injuries, one that he could recall being followed by complete atrophy of the testicle and another by rupture of a testicle with the formation of a hematoma, requiring the removal of the testicle.

I wish to devote most of my discussion to those cases of epididymitis or epididymo-orchitis in which examination provides evidence of inflammation and in which an alleged trauma, either direct or indirect (the so-called strain), is supposed to have been a contributing factor. Such cases are important because the majority of them occur in working men and the question of compensation almost always arises.

I believe that the pertinent question is not whether trauma can initiate . . . light up some dormant pathologic . . . direct trauma or strain can precipitate a clinical attack of epididymo-orchitis.

Wesson stated that "an epididymitis is secondary to a urethritis or seminal vesiculitis, and its occurrence depends on the virulence of the organism and the susceptibility of the patient, the extension to the epididymis inevitably appearing regardless of whether the patient is confined to bed or receives a blow on the testicle."

Crane² discussed the mechanism of the development of epididymitis and stated that under the conditions enumerated an infection of the epididymis is almost

From the Jackson Clinic.

Read before the Section on Urology at the Ninetieth Annual Session of the American Medical Association, St. Louis, May 17, 1939.

sure to occur spontaneously without being associated with trauma. When occurring in a working man, immediately some minor injury in the form of a strain or blow is easily recalled and given credit for the sudden onset of the epididymitis, when in reality the sudden strain or minor blow simply caused the patient to realize that an inflammatory process existed.

From my clinical experience, I find that I must disagree with these opinions. However, I agree with the reports as to the nature of the pathologic process found. Under the circumstances, I believe a brief review of the mechanism of the development of epididymitis is pertinent.

Rolnick,³ who has studied this problem extensively, states that most infections of the epididymis are secondary to infections of the seminal vesicle, extension of the infection along the lumen of the vas deferens being the mode of involvement.

Hematogenous infections occur in a small percentage of cases.

The vesicles may be infected as the result of passage of bacteria from the epididymis through the vas deferens, since the epididymis has the power to excrete bacteria.

The chronic infections of the epididymis, other than tuberculosis, which are frequently seen and termed simple or nontuberculous inflammations, are probably, in the vast majority of cases, of hematogenous origin.

As a result of inflammatory edema about the verumontanum, the ejaculatory duct becomes temporarily occluded. Plugs of pus or mucus also may produce blockage of the ducts. The infected seminal vesicle and ampulla become distended with pus and, being unable to escape through the duct, the pus finally regurgitates through the lumen of the vas to the tail of the epididymis. As a result of active peristalsis of the vas deferens (no reverse peristalsis has been proved to exist) the organisms and pus will be propelled backward with each peristaltic wave of the vas toward the posterior portion of the urethra, the mechanism here being similar to bladder reflux. The infection does not spread by continuity along the mucosa of the vas from the urethra, because the spread is too rapid. Neither can it travel along the lymphatics, for there is no continuous chain of these along the vas to the epididymis.

Kreutzman⁴ states that viable organisms may be present in the vas without causing any symptoms or producing any gross changes. Epididymitis following ligation of the vas is due to a lighting up of a previous vasal infection and not to an infection of the lymphatics or blood stream. Vasitis and epididymitis occur only in the presence of infected urine. Under certain conditions not yet understood, reflux of urine may occur into the vas as it does into the ureter. When the urine is infected, instrumentation doubles the possibility of epididymitis. Chronic prostatitis alone will not cause vasitis or epididymitis.

O'Connor⁵ observed in two cases of prostatic obstruction that silver solution injected into the bladder was found in the vas deferens less than twenty-four hours after instillation.

I have reviewed many of my cases of epididymitis and in every instance found evidence of infection in the form of pus and, in many instances, of organisms

obtained on culture of urine from the second glass. I think, then, that it is only reasonable to assume that trauma in the form of a severe strain could force infected material along the vas to produce acute epididymitis.

In the older textbooks and articles may be found the statement that the male urethra will harbor different strains of bacteria which, "though usually nonpathogenic, may become pathogenic under various stimuli." In this connection, the following case is of interest:

CASE 1.—A. W., aged 23, fell several feet and straddled a rail on a loading platform. He suffered acute pain in both testicles and for some time was unable to continue his work. He came to the clinic three days later (December 1932), at which time the left epididymis and testicle showed swelling graded 1. There was discoloration of the scrotum. Rest and support were advised.

Several days later he noted a urethral discharge; there was no dysuria. He stated that there had not been any previous gonorrheal infection. Examination disclosed a urethral discharge, smears of which showed pus cells and gram-negative bacilli. Cultures were reported as showing *Bacillus coli*. Both glasses of urine were cloudy; the second showed pus, motile bacilli and a few blood cells. Cultures of urine from the second glass showed *B. coli*. The left epididymis still showed enlargement graded 1 and was tender. The left testicle was, by this time, normal. The prostate was of normal size, and examination of the fluid gave negative results on several occasions. Repeated examinations of the urethral discharge revealed no organisms except gram-negative bacilli. With local treatments, the urethral discharge subsided seventeen days after the injury. Here, then, was a typical case of traumatic epididymo-orchitis in which urethritis due to colon bacilli developed, undoubtedly precipitated by the trauma.

If all cases of epididymo-orchitis I observe were as indefinite as to trauma or the so-called strain as the following, they would not cause me so much concern. I would be inclined to the view that the epididymitis occurs as a coincidence and is in no way precipitated by the alleged physical exertion. Certainly this patient's routine work required as much physical exertion as the spading in the garden, the alleged physical exertion:

CASE 2.—C. D., aged 57, a garage operator, came to the clinic in May 1938 on account of pain and swelling of the left testicle of three days' duration. One afternoon after spading in his garden he had noted soreness and pain in the left side of the scrotum. The next day there appeared in the left testicle swelling and pain, which gradually became worse. There were no urinary symptoms and no history of a previous similar difficulty; he stated that he had not had gonorrhea.

Examination disclosed a urethral discharge, smears of which showed gram-negative bacilli and gram-positive cocci. There were no organisms that resembled the gonococcus. The second glass of urine contained pus graded 1, red blood cells graded 2 and motile bacilli. Cultures showed *B. coli*.

There were epididymo-orchitis on the left graded 2 and funiculitis graded 2. The prostate showed enlargement graded 1 and was boggy; the fluid contained pus graded 1, stained smears of which showed no definite organisms. There was no residual urine. There were an inguinal hernia on the right, for which he wore a truss, and a small left direct hernia.

However, this is not the type of case that leads me to believe that trauma as previously defined can and does precipitate an attack of acute epididymitis in the patient who harbors chronic prostatovesiculitis or infected urine. Such a case may be the following:

CASE 3.—H. N., aged 27, came to the clinic in July 1932 complaining of pain and soreness in the left groin and pain and swelling of the left testicle. Five days previously, while he was stepping into his car, a dog jumped on him and in his haste he struck his left groin and the left side of the scrotum on the edge of the car door. The next day, on account of the

swelling and pain which came on soon after the accident, he consulted a physician, who advised rest and cold compresses. The history disclosed that he had had uncomplicated gonorrheal urethritis four years previously.

There was no urethral discharge. The urine was normal. There were subsiding ecchymosis in the region of the left groin and some swelling. The left epididymis showed swelling graded 2 and was painful. The left testicle was swollen and painful. The prostatic fluid contained pus graded 1, smears of which showed gram-positive cocci and gram-negative bacilli; the fluid was not cultured. The patient left my care seventeen days after I first saw him, at which time the globus major showed enlargement graded 1 and was hard and painful. Four months later he wrote me that a hard swelling had developed next to the left testicle. He was advised to consult a urologist in his city. The insurance company refused liability on account of the history of gonorrhea. This man undoubtedly had trauma followed soon by pain and swelling of the epididymis and testicle, traumatic epididymo-orchitis, yet at the time I saw him the lesion was, in my opinion, of an inflammatory type.

The two following cases are typical of the ones I had in mind when I prepared this discussion:

CASE 4.—D. L. S., aged 52, had been a patient at the Jackson Clinic since 1927. In July 1937 he came for a physical examination and stated that at times he had frequency of urination. The prostate was normal in size; the fluid contained pus graded 1. The urine was alkaline and contained pus graded 1 and motile bacilli. There was no residual urine. He was given a bladder instillation of 5 per cent mild protein silver solution and methenamine and sodium acid phosphate by mouth. At subsequent visits he did not complain of the frequency and he did not report for further observation. His history disclosed a gonorrheal infection at the age of 20.

July 22, 1938, while he was assisting in assembling a combine mower, the full weight of the machine was thrown on him for a few seconds, requiring great physical exertion. July 24, two days later, he noted an ache low in the back on the right; the next day he had pain in the right testicle, frequency and some weakness of the urinary stream. When seen July 26, four days after the physical exertion, he complained of pain and swelling of the right testicle, frequency and dysuria.

Examination disclosed tenderness over the right iliac joint and epididymitis on the right graded 2. The prostate was boggy and the fluid contained pus graded 4, smears of which showed no organisms resembling the gonococcus. Cultures showed *B. coli*. The second glass of urine showed pus graded 4 and red blood cells graded 1; the cultures showed *B. coli*. Two days later the temperature was 102 F. and there were epididymitis on the right graded 4, orchitis on the right graded 2 and funiculitis graded 2. There was marked thickening of the vas. Funiculitis and vasitis were not present at the time of the first examination. Thirty-five cc. of hazy hydrocele fluid was aspirated.

There was evidence that this patient had infected urine and low grade prostatitis one year previously, although during the interval he could not recall having had any local symptoms. He was given sulfanilamide; rest, heat and support were employed, and the acute process rapidly subsided.

The prostate was massaged at weekly intervals, and 5 per cent mild protein silver solution was instilled in the prostatic portion of the urethra with a No. 8 French soft rubber catheter. After a series of eight or ten such treatments the prostatic fluid showed only a few pus cells and the urine had appeared normal microscopically and on culture for several weeks. Treatments were discontinued for a month, and then examination disclosed pus graded 2 in the prostatic fluid. The next day, after the second treatment, he noted frequency and dysuria and pain in the side of the sacral region. The next evening these symptoms persisted, and while attempting to open a storm window by pushing with his foot, he slipped and fell, impinging his scrotum between his buttocks and the floor. There was acute pain in the scrotum, which lasted for some time, followed by dull pain. The next morning the scrotum was swollen and

painful. Examination disclosed epididymitis on the left graded 2 and pus in the second glass. In the latter instance the epididymitis would certainly have developed, but in my opinion it was hastened and aggravated by the physical trauma.

CASE 5.—E. C. J., aged 33, an attorney, was admitted in March 1937 on account of fever, pain and swelling of the right testicle. The history disclosed that on a Saturday he had lifted a heavy box of books requiring unusual physical effort. He was not aware at the time of any pain. On the Monday following he noted pain in the right side of the back and the right loin, with radiation to the right testicle. Within a few hours after the onset of the pain in the loin he noted constant pain in the right testicle, followed soon by swelling of the testicle. On this day he had definite rigor followed by fever. There was no history of recent acute illness such as grip or coryza and no history of previous urinary symptoms except that in 1935, after an appendectomy and while still in the hospital, he had an attack of what his physician thought was renal colic on the right side. His history disclosed that he had had uncomplicated gonorrheal urethritis six years previously.

Examination disclosed a mucoid urethral discharge, which on smear showed gram-negative bacilli and gram-positive cocci. Both glasses of urine were cloudy; the second contained pus graded 4. The cultures showed staphylococci and *B. coli*. The prostate was boggy; no fluid was expressed at this time. Twenty days later a smear of the prostatic fluid showed gram-negative bacilli and, on culture, *B. coli*. An original roentgenogram revealed no evidence of calculi. There were tenderness over the right renal area, epididymitis on the right graded 3 and orchitis graded 1. Five days after admission, the right epididymitis was incised from pole to pole. No frank suppuration was found; the cultures showed *B. coli* from two separate areas. The pathologic diagnosis was acute and early suppurative epididymitis with no evidence of tuberculosis or neoplasm.

The attack of pain which the patient had while in the hospital after the appendectomy was probably due to pyelonephritis, and no doubt he had residual prostatitis.

I frankly admit that such cases do not prove or disprove the role of the sustained "strain" in precipitating the attacks of epididymitis; neither do my observations lead me to believe that the attacks described would have occurred had the men been confined to bed.

I think that one should attempt a proper evaluation of all factors concerned in a given case. It is to be noted that the traumas or strains under consideration in the cases I am discussing were of a definite nature, and I would not consider any which were not.

The two following cases are of interest in that the same type of trauma or strain was alleged in the two instances and in both the question of compensation arose:

CASE 6.—J. J. S., aged 52, a meat cutter, came to the clinic in July 1935 complaining of pain and swelling of the right testicle of several days' duration. Nine days previously, while he was carrying a quarter of beef, his foot slipped and immediately he experienced sharp pain followed by discomfort in the right inguinal region. The next day he noted some swelling of the right testicle and he began wearing a suspensory, which afforded him some relief. The day before admission, after an automobile ride, the pain became much worse and the swelling increased. There were no urinary symptoms and no urethral discharge. There was no history of gonorrhea. The right epididymis showed swelling and tenderness graded 2; the right testicle, swelling graded 2 and tenderness. The prostate was slightly enlarged and firm; the fluid contained a few pus cells but after several examinations was graded as to such cells less than 1. The urine showed pus graded 2 in clumps, many motile bacilli and, on culture, *B. coli*. With appropriate treatment, the process subsided in nine days.

CASE 7.—E. K., aged 42, a meat cutter, was seen at his home Dec. 11, 1936, on account of redness of the scrotum, pain and swelling of the left testicle and fever. The history disclosed that on Thanksgiving day, while he was attempting

to place a quarter of beef on a block, his foot slipped and he experienced sharp pain in the left groin. He sat down for a while but the discomfort in the groin continued, and about December 7 pain and swelling of the left side of the scrotum was noted, having gradually increased. When I saw him December 14 there was epididymitis on the left graded 2; the vas was thickened and infiltrated throughout its palpable length. The prostatic fluid contained pus graded 4; several stained smears failed to reveal gram-negative diplococci. The second glass of urine contained pus graded 1 in clumps and motile bacilli. The history disclosed that the patient had had gonorrhea five or six years previously.

Again I must admit that the trauma (strain) as a factor in precipitating these lesions was questionable, but neither can I admit that the trauma served only to call the patient's attention to a pathologic process that was already in the act of developing. Had the pathologic process been tuberculosis, tumor or a gumma, then I could easily have seen that this was the case.

Some writers speak of the ease with which gonococci are found in the seminal fluid, prostatic fluid and urine by smear in such cases. I have not found it easy to demonstrate them. However, my efforts have been confined to a study of stained smears of the seminal and prostatic fluid and urinary sediment, since facilities for culture of the gonococcus are not at my disposal, and perhaps the interval between the infection and the development of epididymitis was too long.

In the following case I made repeated smears in searching for the gonococcus, because the history disclosed that the patient had had a gonorrheal infection four years previously with no complications and no recurrence of the discharge:

CASE 8.—B. P., aged 41, came to the clinic in March 1936 complaining of pain and swelling of the right side of the scrotum of several days' duration. Two days after heavy physical exertion sustained while pushing an automobile from a snow drift, he noted pain in the lower right abdominal quadrant and the right inguinal region. It did not disable him, but the day after he noted pain and swelling in the right side of the scrotum. The general examination gave negative results except to disclose a temperature of 101 F. The right epididymis was acutely tender and showed swelling graded 3. The urine contained pus graded 4. The prostate showed enlargement graded 1 and was boggy and tender, and the fluid contained pus graded 4; several smears revealed no gram-negative diplococci.

With support, heat and rest, the pain, swelling and temperature gradually subsided. Six days after his first visit he was awakened in the early morning with a dull aching pain in the right lower quadrant which remained constant. When he was seen during the day there was some tenderness on palpation along the inguinal canal and in the right lower abdominal quadrant. The swelling in the epididymis was subsiding except in the upper pole, which still showed swelling graded 2 and was tender. There was crepitation in the tunical structures. The prostate was smaller than at the previous examination. The urine contained clumps of pus and motile bacilli. Rest and heat were advised. About 10 o'clock that night he was seen again on account of severe pain in the right lower quadrant radiating to the back, the right renal region and the loin. The temperature was 103 F. There was no frequency or dysuria.

Examination revealed tenderness over the right renal area and marked tenderness just above the middle of Poupart's ligament on the right. The epididymis was as in the morning. The vas, as far as it could be palpated, was about the size of a pencil and very tender. The prostate and right seminal vesicle were boggy but not appreciably enlarged or tender. The diagnosis was acute pyelonephritis (on the right) and probably some degree of ureteral stasis due to edema and swelling of the vas. Hot sitz baths and hot rectal irrigations promptly relieved the pain on the right side and pain on the

right renal region. The patient was subsequently treated by the usual methods for his infection of the prostate and the urinary tract.

A review of several of the cases under discussion reveals that vasitis and funiculitis developed several days after the onset of the epididymitis, suggesting that the vas was involved by infected material forced into its lumen from above; the vas is more resistant to infection than the epididymis, and thus the delay in the development of the vasitis. Or else the vas was involved by extension of the inflammatory process from the epididymis.

Whether direct trauma such as a blow could predispose to the localization of bacteria from some other focus of infection is another interesting and debatable question.

Buckingham,⁶ in his discussion of nonspecific metastatic epididymitis, observed that such lesions are seen most often after infections of the upper respiratory tract, after acute and chronic coccic infections or in the course of any disease in which bacteremia may arise. He further stated that there is a little doubt that slight trauma to the scrotal contents during the course of any acute infection tends to lower the threshold of resistance of the tissues and predisposes to the localization of the infection in the epididymis and that the primary focus could continue to feed the damaged part. He also stated that during the course of any twenty-four hours there are undoubtedly a few cocci circulating in the blood stream of many healthy persons. A coupling of this with trauma at the correct time might account for some of the infections in which the primary focus is not demonstrable. He also stated that trauma undoubtedly plays an important though secondary part in all infections of the genito-urinary tract.

It is evident that such statements are merely theories, but in my opinion they are plausible theories.

For the sake of brevity, I shall report only one case in which direct trauma was, I believe, the precipitating factor in lighting up a dormant epididymal infection, although I have observed other such cases. Had the patient received a blow from a pick or shovel handle while at work, I am sure the same process would have been precipitated.

CASE 9.—H. W., aged 65, was sent to the clinic from the county dispensary in September 1933 on account of pain and swelling in the right side of the scrotum and pyuria; there were no vesical symptoms. He had undergone a suprapubic prostatectomy five years previously. During convalescence, epididymitis developed on the right side, followed by a hydrocele, which was tapped several times. Several days prior to admission, while he was playing with or holding his grandchild, the child accidentally kicked him on the scrotum. After the kick there was severe pain in the scrotum, and the next day there were swelling and fever. He was confined to bed for a few days. Examination disclosed a hydrocele on the right, from which 150 cc. of turbid fluid was aspirated. The epididymis showed enlargement graded 1 and was hard and extremely tender. After the acute reaction had entirely subsided, the hydrocele was treated by the injection method.

CONCLUSIONS

Traumatic epididymo-orchitis is a distinct clinical entity, and cases coming under medical observation are relatively infrequent.

My experience leads me to believe that clinical attacks of inflammatory epididymo-orchitis can be precipitated by trauma either direct or indirect (the so-called strain). In the one instance the direct trauma serves to light

6. Buckingham, W. W.: Nonspecific Metastatic Epididymitis, *J. Urol.* 31: 87-101, 1934.

up a dormant infection or, by lowering the threshold of tissue resistance, invites infection from some distant focus, and in the other the strain serves to force infected material such as urine, prostatic fluid or seminal fluid along the lumen of the vas to the epididymis.

16 South Henry Street.

ABSTRACT OF DISCUSSION

DR. MILEY B. WESSON, San Francisco: This paper is based on a false hypothesis contrary to the laws of physiology and mechanics, that intra-abdominal pressure from a strain squeezes infected urine into the seminal vesicles and the ejaculatory ducts and that the pressure on the seminal vesicles causes their infected contents to backfire into the epididymis. The effect of intra-abdominal pressure on the seminal vesicles is negligible compared to the passage of a scybalum, which is known frequently to cause spermatorrhea but never epididymitis. Constipation is potentially a greater source of danger than the strain of lifting. Orgasm without ejaculation is a not uncommon complaint in cases of seminal vesiculitis and yet neither causes epididymitis. I question that the male urethra harbors nonpathogenic organisms that become pathogenic under proper stimulation. John Hunter lost an argument of that kind when he inoculated himself from a urethral discharge and developed syphilis instead of gonorrhea. The doctrine of "latent infection" is intriguing, and we are all familiar with typhoid carriers and the fact that tetanus spores have been found in the scars of shrapnel war wounds, but nowhere could I find an authoritative statement to the effect that pyogenic organisms could live and multiply in an epididymis or any other apparently normal tissue. Autopsy surgeons make sections of the various organs as a routine, and although they frequently report prostatitis they never find organisms in a supposedly healthy epididymis or vas. Epididymitis is due to infection by organisms from the seminal vesicles. How long they are en route, we do not know. There may be an intervening vasitis and the host will probably complain of a "hernia from lifting." After the invaders have taken over the epididymis there is an incubation period before there are any subjective or objective symptoms; consequently these may develop while he is in bed. It is contrary to the precepts of bacteriology to have the entire process take place coincidentally with a strain or within a few hours afterward. If certain isolated statements are separated from the qualifying context and quoted as authoritative, they will prove to be pernicious and of far reaching deleterious effect to private practice because of the medicolegal importance of the subject. Furthermore, unless we check the tendency to make trauma again the universal etiologic agent, we are going to witness shortly the beginning of the end of the private practice of medicine.

DR. EDWARD CATHCART, Detroit: It is apparent that it is about as safe to discuss traumatic epididymo-orchitis as to discuss religion. You either believe in it or you do not. The thing that impresses me about this discussion is that it is not a medical problem; it is an insurance problem. Our treatment, whether trauma is alleged to be the cause or whether straight infection is alleged to be the cause, is the same. Our annoying obligation is to the injured person if he is injured and to the insurance company if it is not liable. It would appear that our approach to the clinical evaluation of these cases is one of overreaching. I believe the difficulty does not lie with our opinion as to whether epididymo-orchitis is traumatic or not; it is a matter of how insurance contracts are drawn. It has been increasingly easier to be a referee in this group in the past several years in Detroit because of the ability that we now have to allege that epididymo-orchitis is a compensable illness and not an accident. I think that our efforts, so that we may do reasonable and justifiable service both to the complainant and to the insurance company, calls for further cooperation in the more careful drawing of contracts. It is an unimportant medical problem but a very important insurance problem.

DR. GEORGE H. EWELL, Madison, Wis.: I have had great pleasure in the last year and a half corresponding with Dr. Wesson about this paper and about his views on this subject.

EXPERIMENTAL AND CLINICAL GRANULOMA INGUINALE

AND

RICHARD TORPIN, M.D.

AUGUSTA, GA.

Many investigators have asserted that they have cultured an organism comparable to the Donovan body on a variety of mediums, particularly Sabouraud's.¹ However, the types of organisms cultivated by the various investigators have not been identical. Moreover, subcutaneous inoculation of such organisms into human beings has failed in every instance to reproduce the typical lesions of granuloma inguinale.² It is therefore doubtful that the etiologic agent of this disease has ever been cultivated. On the other hand we have on several occasions aspirated material from unruptured inguinal abscesses (pseudobuboes) of granuloma inguinale in which the sole micro-organism present was the Donovan body. In attempting to corroborate the observations of previous investigators we met with utter failure to cultivate the Donovan body or any other organism from this material.³ Since a pure culture of Donovan bodies was contained in the aspirated pus, we felt that some light might be thrown on the controversial issues concerning the causal agent of granuloma inguinale if subcutaneous injection of this material could be followed by exact clinical reproduction of the disease as well as recovery of the organism again in pure culture.

PUS FROM A PSEUDOBUBO CONTAINING DONOVAN BODIES IN PURE CULTURE

CASE A.—S. W., a Negro woman aged 24, was readmitted to the University Hospital with pulmonary tuberculosis and coincident granuloma inguinale of the perineum (proved by smears and biopsy). While she was hospitalized and under observation an indurated inguinal swelling appeared some three months after admission (fig. 1). This gradually ripened in two weeks into a fluctuating abscess (fig. 2). Ito-Reenstierna, Frei and blood Wassermann reactions were negative. The abscess was aspirated and only Donovan bodies could be demonstrated in smears. Culture of the pus on a variety of mediums failed to yield any growths. Ulceration of the pseudobubo followed

about ten days later exhibiting typical raised red granulation tissue. The lesions responded slowly to therapy (fig. 3). A small slightly tender lymph node in the right inguinal region was palpable at this time. It was excised along with two smaller lymph nodes for microscopic study.

Fig. 1 (case A).—Granuloma inguinale of perineum and vulva. One year after onset, indurated swelling in left inguinal region appeared.

THE EXPERIMENTAL PRODUCTION OF GRANULOMA INGUINALE

EXPERIMENTAL CASE 1.—Some of the aspirated pus from the pseudobubo in case A was inoculated subcutaneously into both groins and the left thigh of another tuberculous patient (H. G.). What followed is outlined in the accompanying table. Donovan bodies were recovered on the thirty-third and forty-third day respectively from the left (fig. 4) and right inguinal

Fig. 2 (case A).—Fourteen days later: fluctuating inguinal abscess (pseudobubo of granuloma inguinale).

abscesses to the exclusion of other micro-organisms as proved by culture. Suffice it to say that the classic picture of the disease was reproduced in about fifty days (fig. 5). Since the lesion responded very slowly to therapy, surgical excision of the lesions along with several small inguinal nodes was undertaken on the eighty-fourth day.

EXPERIMENTAL CASE 2.—A piece of tissue, rich in Donovan bodies and containing relatively few secondary bacteria, was transplanted from an open lesion of granuloma inguinale to the right groin of a volunteer Negro man (R. H.) aged 35. Twenty days later a small indurated nodule appeared in the groin. On the forty-fourth day a fluctuating inguinal abscess was present (fig. 6a). Aspiration yielded a few cubic centimeters of blood-tinged pus rich in Donovan bodies but no bacteria, as proved by further cultural studies. A classic picture of inguinal granuloma soon followed (fig. 6b and c).

EXPERIMENTAL CASE 3.—F. H., a Negro volunteer aged 34, was inoculated subcutaneously in the groin with 0.5 cc. of exudate abundant in Donovan bodies and no bacteria. In three weeks a small swelling about 0.5 cm. in diameter was noticed at the site of inoculation. In five weeks the swelling increased to about 3 cm. in size. At this time some bloody exudate was aspirated and examined and Donovan bodies were found in large numbers. No bacteria developed when some of the exudate was inoculated into blood agar slants and Sabouraud's medium.³

EXPERIMENTAL CASE 4.—Pieces of tissue from lesions of granuloma inguinale were transplanted into each groin of a Negro woman (M. McC.) aged 18. Twenty-one days later

Fig. 3 (case A).—Two months later: inguinal and perineal granulomas responding slowly to therapy.

small indurated nodules appeared. After the twenty-sixth day these began to subside and no lesions have developed to this day, more than one year afterward. Mention however must be made that this patient was schizophrenic and received a series of intravenous injections of metrazol during the interval of this experiment.

Numerous investigators have unsuccessfully tried to induce experimental lesions in human beings by inoculation of cultures of micro-organisms cultivated from the human lesions. DeMonbreun and Goodpasture isolated a gram-negative bacillus belonging to the aerogenous group with morphologic characteristics of the Donovan bodies. They failed to induce granuloma inguinale by subcutaneous inoculation of such cultures in a group of six human volunteers. Working with human tissue rich in Donovan bodies they were, however, able to produce by repeated inoculation abortive infections in *Macacus rhesus*. McIntosh successfully transferred the disease from one individual to another by transplantation of tissue. However, Campbell⁴

4. Campbell, M. F.: *Etiology of Granuloma Inguinale*, Ann. J. M. Sc. 174: 670 (Nov.) 1927.

criticized the deductions from such an experiment since the tissue was from an open infected lesion and must have carried other organisms with it. The role played by some symbiotic organism could not be ruled out. On the other hand the experimental production of granuloma inguinale by using the exudate from an unruptured pseudobubo which contained no other demonstrable organism obviates any similar criticism as that directed at McIntosh's experiment. In his two cases McIntosh determined the incubation period as forty-seven and forty-two days respectively. It is apparent from our cases that it is difficult to determine exactly when the disease begins. It is well to remember that individual susceptibility varies, for in one of our patients the disease failed to develop.

THE CONCEPT OF THE PSEUDOBUBO OF
GRANULOMA INGUINALE

The bubo has been defined as a suppurative adenitis. Buboes are seen with marked frequency in venereal lymphogranuloma and chancroid disease, often in syphilis, rarely in gonorrhea.⁵ In the aforementioned group the subacute inguinal adenitis is always secondary to a

Fig. 4 (case 1).—Experimental production of granuloma inguinale, thirty-third day.

primary focus in the genital zone. Is the inguinal lesion in granuloma inguinale a primary one? With what frequency does the inguinal lesion accompany one on the external genitalia? How often is the classic bourgeoning inguinal granulomatous ulceration preceded by a localized indurated swelling or fluctuating abscess in the inguinal region which simulates a bubo prior to rupture or incision? (fig. 7). These points seem to have escaped the scrutiny of most authors on granuloma inguinale and certainly deserve further elucidation.

In reviewing our own series of cases we were struck by the frequency with which the inguinal lesion was preceded by a primary focus on the genitalia (figs. 1, 7 and 8). Poindexter⁶ noted that in patients with granuloma inguinale "frequently an operation for inguinal adenitis (buboes) was performed which did not heal." In the two cases of inguinal swelling reported by Gruhitz⁷ there was an inguinal swelling in one which

was incised, in the other there was one which was pricked, and in both healing did not follow. In case six reported by Goldzieher and Peck they mention that "the primary lesion was a small pimple adjacent to the urethral opening, which appeared three weeks after

Fig. 5 (case 1).—Classic picture of granuloma inguinale produced experimentally, fiftieth day.

intercourse. . . . He then noticed a lump in the right inguinal region." Typical ulcerative lesions of granuloma inguinale later developed. In two of the

Fig. 6.—Experimental granuloma inguinale: a, forty-fourth day; b, sixtieth day; c, sixty-sixth day.

three cases reported by Shattuck, Little and Coughlin⁸ it is noted that a history of a previously incised bubo was recorded. Numerous similar examples are to be

found in the literature. In the excellent series of cases studied by Lynch,⁹ bilateral buboes occurred in case 8. His interpretation of this case that it "is apparently a granuloma of the perineum, then extending to ruptured

Fig. 7.—Pseudobubo of granuloma inguinale one day after aspiration of inguinal swelling. Inguinal lesion was preceded by penile lesion.

gonorrheal buboes in the groins, coupled with active gonorrhea and syphilis" must be considered as gratuitous. Nair and Pandalai¹⁰ observed that granuloma

Fig. 8.—Inguinal lesion preceded by a primary focus on the penis.

inguinale followed on incision of buboes. They failed to realize that the incised inguinal swelling was at the onset but a phase of the disease and offered the naive

explanation that surgical trauma predisposes to granuloma inguinale.

Traditional teaching has repeatedly emphasized that granuloma inguinale is a disease of the skin and corium and not of the lymphatics.¹¹ Fox¹² stresses that "one of the striking features of the disease is the absence of enlargement of the neighboring lymphatic glands." The following statement by Harris¹³ probably represents the general impression: "There is usually no inguinal involvement, never bubo formation." On the other hand, what did Patch¹⁴ mean when he wrote "Seldom are the lymph glands involved. When they are, they suppurate and break to the surface and form large granulation masses." It is possible that Patch was quoting Mayer and da Rocha Lima,¹⁵ whose authorities in turn were Thierfelder and Thierfelder Thillot.

The question arises How does this disease gain hold in the inguinal region following primary infection of the external genitalia? Excised tissue from the inguinal ulcerations studied microscopically by us has shown a diffuse granulomatous reaction in the papillae, corium and subcutaneous tissues and is not comparable to the adenitis found in venereal lymphogranuloma, chancroid or syphilis. Hence by definition it is not a bubo but a

Fig. 9 (case B).—Cervical abscess; extragenital granuloma inguinale.

subcutaneous granuloma. We have therefore coined the term "pseudobubo" to describe this inguinal swelling which so frequently simulates the bubo of the other venereal diseases. It would seem therefore that the clinical observation by Thierfelder and Thierfelder Thillot¹⁶ that "suppurative buboes result which perforate through the skin and are characterized by granulation tissue raised high above the surface" is now subject to proper interpretation. By what route does the disease reach the inguinal region? Autoinoculation occurs but the frequency with which the inguinal region alone is involved after genital infection is more than mere coincidence. What role do the lymphatics play in the dissemination of this disease? A suggestion may be found in the analysis of the following case:

STUDY OF THE LYMPH NODES IN GRANULOMA INGUINALE

CASE B.—M. W., a Negro woman aged 31, was admitted to the University Hospital with granuloma inguinale of the vulva, vagina, inguinal regions and right side of the neck.¹⁷ Tissue sections from the neck and inguinal ulcerations revealed the characteristic pathologic condition and the pathognomonic cells with Donovan bodies. Several inguinal lymph nodes from the left groin were excised at the same time and microscopic study of the nodes revealed nothing unusual. Her response to fuadin therapy was remarkable. One year later she returned with a recurrence on the vulva and groins and a small subcutaneous abscess on the left side of the neck (fig. 9). Aspiration of this abscess revealed typical Donovan bodies. The tissue underlying this cervical abscess was indurated and some of the deep nodes were enlarged and palpable. Surgical excision was performed of the neck lesion with the underlying lymph nodes as well as the right inguinal lesion and inguinal lymph nodes.

Fig. 10 (case B).—Section from cervical lymph node exhibiting focal suppuration and perilymphadenitis.

Microscopic examination revealed that the areas of ulceration of the neck and the inguinal region exhibited the characteristic picture of granuloma inguinale with the pathognomonic cells containing the Donovan bodies.¹⁸ The most superficial cervical lymph node, just beneath the area of ulceration, was enlarged to 1.5 cm. in diameter and contained foci of suppurative inflammation (fig. 10). In these foci many Donovan bodies were demonstrated (fig. 11). One of the inguinal lymph nodes similarly was involved. In two other small lymph nodes from the inguinal region no Donovan bodies were seen; however there was perilymphadenitis with lymphocytic infiltration of the capsule.

The demonstration of the pathognomonic cells filled with intracyclic spaces containing Donovan bodies in

suppurative lymph nodes opens new avenues of thought and room for speculation. Inguinal lymph nodes were studied microscopically in three other cases. One small inguinal lymph node removed at autopsy in a patient

Fig. 11 (case B).—Section of cervical lymph node under high power, showing the pathognomonic cells filled with intracyclic spaces containing Donovan bodies. Note the accompanying polymorphonuclear leukocytic response.

Fig. 12.—Camera lucida drawings to illustrate possible life cycle of Donovan bodies (Dienst), reduced from a magnification of 1,500 diameters: 1. Mature extracellular organisms with red blood cells. 2. Large mononuclear endothelial cell showing early invasion with Donovan bodies. 3. with extensive granuloma inguinale of the pudenda revealed an overwhelming infection with Donovan bodies. It seemed that almost the whole lymph node was replaced with large endothelial cells containing

encysted Donovan bodies, accompanied by a very mild leukocytic response. In case A and experimental case 1, the excised inguinal nodes showed moderate endothelial hyperplasia but no Donovan bodies. Apparently the Donovan bodies are not always found in the regional lymph nodes. What conclusions, if any, may be drawn from such observations to account for the frequency with which inguinal pseudobuboes follow primary genital infection? Is it possible that Donovan bodies travel along the lymphatics and reach the regional lymph nodes where temporary though mild focal reactions and perilymphadenitis occur but ultimately subside? The hypothesis is advanced that during this process, by some means at present not understood, the Donovan bodies reach the corium, where they flourish best. Here the process may be subacute, resulting in a subcutaneous abscess, or it may be chronic and a massive granulomatous tissue bulges the overlying

in the specific exudate stored four weeks in the ice box. The encapsulated form is also the last to disappear after attempted cultivation in vitro.

GROWTH REQUIREMENTS

The Donovan bodies are strictly tissue parasites of man. The organisms are not pathogenic for rabbits, guinea pigs, rats and mice when pure cultures are inoculated intraperitoneally, intratesticularly or subcutaneously. Several mice were inoculated intracranially and no pathogenic manifestations developed. Chick embryos were also inoculated with no demonstrable effects.

The Donovan body is not culturable in vitro by methods used to propagate fastidious bacteria, Rickettsial bodies and viruses. Such enriched mediums as N. N. N. medium, Loeffler's serum, infusion agar with defibrinated human blood, infusion agar with defibrin-

epidermis. Finally ulceration occurs with the characteristic clean raised granulation tissue. Hence the pseudobubo of granuloma inguinale.

THE NATURE OF THE DONOVAN BODY

The life cycle of the Donovan body of granuloma inguinale in the host's tissue is apparently a simple one. The organism invades the large mononuclear endothelial cells of the infected tissue until the cell is eventually destroyed and new cells are invaded. Occasionally neutrophilic leukocytes and perhaps the mononuclear leukocytes phagocytize and destroy the extracellular encapsulated parasites, but the invasion of the large mononuclear endothelial cells occurs more rapidly than does phagocytosis, so that eventually more tissue is infected. The parasites reproduce by multiple segmentation or schizogony in the large mononuclear endothelial cells. Sometimes there may be as many as six foci of reproduction within one large mononuclear cell. The immature bodies resulting from multiple segmentation mature within cystic spaces created in the parasitized cells until each organism is fully developed and apparently encapsulated. The infected cell finally ruptures and the mature Donovan bodies are liberated (fig. 12).

The encapsulated form is the most resistant stage of the parasite, as it can be demonstrated by Wright's stain

ated rabbit blood, various solutions of human serum in buffered dextrose solution, tubes of serum with minced rabbit spleen and tubes of minced chick embryo were inoculated with exudate rich in Donovan bodies. This exudate was obtained by aspirating aseptically unruptured pseudobuboes in which the Donovan bodies were observed in pure culture. Some of the transplants were incubated as long as two months and at no time was multiplication of the parasites observed. Serial transplants in buffered human serum on N. N. N. medium containing blood was attempted with no multiplication of the parasites.

EVIDENCE FAVORING THE PROTOZOAN NATURE OF THE DONOVAN BODIES

Donovan bodies are probably protozoans, particularly sporozoans, as evidenced by the following observations: 1. The organism is highly selective for its particular host. 2. The organism reproduces in living tissue and only in large mononuclear endothelial cells. 3. The method of reproduction is by multiple segmentation within specific tissue cells. 4. Antimony and potassium tartrate has therapeutic action. 5. Infection recurs after apparent healing.

SUMMARY

Granuloma inguinale was experimentally reproduced in three human beings but failed to develop in one. It failed to develop in laboratory animals in spite of

repeated attempts. When the disease was reproduced, the course was comparable in every way to that seen in spontaneous cases. Donovan bodies were recovered to the exclusion of other organisms from the pseudobuboes that developed in each of the three patients. The incubation period could not be determined; however the classic picture of the disease was full blown in about fifty days. This is the first instance in which granuloma inguinale was experimentally produced in a human being by the use of an exudate which contained only the Donovan body and no other demonstrable organisms.

The pseudobubo that so frequently follows a primary focus on the external genitalia is not an adenitis *per se* but a subcutaneous granuloma. The histopathologic study of regional and underlying lymph nodes revealed but a moderate endothelial hyperplasia. However, in two patients, one of whom also had extragenital involvement, Donovan bodies were demonstrated in the underlying cervical and inguinal lymph nodes, and in the other in one regional inguinal node. Such observations prove that the Donovan body can and does travel by way of the lymphatics. The hypothesis is presented that Donovan bodies may reach the lymph nodes, where temporary though mild focal reactions with perilymphadenitis occur. During this process Donovan bodies may reach the papillae and corium of the overlying skin and set up a subcutaneous granuloma. Here the process may be subacute, resulting in a subcutaneous abscess, or may be chronic and a massive granulomatous tissue bulges the overlying epidermis. Hence the pseudobubo, for prior to rupture and the burgeoning of the typical raised granulations it simulates the bubo of the other venereal diseases.

The nature of the Donovan body remains an enigma to most students of the subject. Contrary to the many reports on the isolation and culture of an organism comparable to the Donovan body, it is doubtful whether the causal agent of granuloma inguinale has ever been cultivated. Such cultivated organisms on inoculation into human beings have failed in every instance to reproduce the disease. The method of reproduction in mononuclear endothelial cells and the growth requirements of the organism as well as the clinical behavior of the disease lead us to assume that the Donovan body is a sporozoan.

ABSTRACT OF DISCUSSION

DR. H. M. ROBINSON, Baltimore: This is an important and significant contribution to a puzzling condition. Thirty-five years ago Donovan reported that certain encapsulated organisms were the cause of granuloma inguinale. Many have since confirmed this but it has not yet been accepted by all authorities. In September 1937 Butts stated that spirochetes and rapidly motile bacilli, found in eight cases of granuloma inguinale, were the cause of this disease, because the administration of antimony compounds caused loss of motility and finally disappearance of these organisms. Certainly, such organisms can be demonstrated in the superficial secretion from the surface of the lesions, both by dark field examination and by stained smears, but are not found after the surface detritus and pus has been completely removed or in material obtained from the base of the lesion. Morphologically these spirochetes are of the refringens type and the motile bacteria are fusiform bacilli. On the other hand, the encapsulated and nonencapsulated organisms known as the Donovan bodies are to be found in all undoubted clinical cases of granuloma inguinale and, if material is obtained from the base of the lesion, only these bodies are found. The authors have reproduced a characteristic clinical picture of the disease by injecting material rich in Donovan bodies. That they have not been able to grow Donovan bodies

in any of a variety of mediums does not discredit their work. I also have tried but have failed to grow Donovan bodies on any of several mediums. I have not seen pseudobuboes or found any associated palpable lymph nodes. None of the five cases at present under my care present these lesions. Regarding the therapeutic results of the antimony salts, I have stated heretofore that the antimony salts may be used as a therapeutic test in granuloma inguinale. My later impression is that this is too radical a statement, because one obtains good results with the antimony salts only in early cases, whereas in late cases results with these drugs are generally disappointing. Unfortunately there is no easy method of diagnosis for this disease. Only by careful technic in making smears and the careful staining and demonstration of Donovan bodies can the diagnosis be made.

DR. S. WILLIAM BECKER, Chicago: A comparatively new concept has been presented that granuloma inguinale may be not simply a local disease. I should like to mention a case in which the infectious organism not only had spread into the lymphatic nodes but had become actually systemic. The patient had been treated in various Chicago clinics for a good many years, finally was given up as hopeless and went to Oak Forest, which is a home for hopeless invalids supported by Cook County. At autopsy lesions of granuloma inguinale were found in the intestinal tract and the ribs. The pelvic structures were involved, probably by direct extension. As far as I know, this is the first case on record in which systemic lesions have been seen and I have every reason to believe that in this case at least it was probably a blood borne systemic infection. It will be reported by Dr. Humphreys.

DR. ARTHUR G. SCHOCH, Dallas, Texas: I should like to mention briefly one case of pseudobubo of seven I have observed in the last year and a half with proved granuloma inguinale. A Negro woman had typical lesions on the genitalia. The pseudobubo responded to treatment along with the lesions of the perineum. I am interested in esthiomene, a so-called entity that has two factors, elephantiasis plus ulceration. I have a paper accepted for publication in which I think I have three proved cases of typical esthiomene due to granuloma inguinale and not to the virus of venereal lymphogranuloma. I have comparatively little difficulty in demonstrating the Donovan body. In the last year and a half I have looked, I think faithfully, for the so-called large giant cell which is supposed to be pathognomonic in biopsy specimens described by Greenblatt, Dienst, Pund and Torpin and I have been unable to date to demonstrate that cell.

DR. SAMUEL GOLDBLATT, Cincinnati: The results in Cincinnati with both fuadin and antimony tartrate medication have been rather disappointing. Early in my experience it was noted that patients who showed toxic reactions, chiefly a generalized toothache, following the administration of the antimony derivatives usually recovered rapidly and remained well. When there were no toxic manifestations to these drugs the lesions usually did not respond. After a fairly extensive experience with the antimony salts I began to utilize electrosurgical excision of the lesion with coagulation at the base. I obtained very good results. Recurrences were few and were seen only during the early conservative period when I was afraid to remove too much. The line of excision must extend from 0.5 to 1 cm. outside the border of any palpable lesion. Recently, and this is too recent to have very much significance, I have seen some of these pseudobuboes described by the authors. Under the probably mistaken idea that there might be venereal lymphogranuloma associated with the granuloma inguinale, I gave the patient sulfanilamide in fairly large doses. The response was surprisingly good. Whether these good results will continue in the future, I do not know. It might be worth while to investigate the effect of large doses of sulfanilamide or even sulfapyridine in the treatment of granuloma inguinale.

DR. FRED D. WEIDMAN, Philadelphia: In one respect I was disappointed in the reading of this paper because a most interesting phase was perforce skimmed, namely some of the peculiar characteristics of the micro-organism. As shown on the screen, it would appear that they were occurring in clusters within a capsule and, furthermore, that the parasites were much fewer in the center than in the periphery of the aggregation. That

recalls something of the order of a fungous micro-organism. It is well known that *Coccidioides immitis*, for example, will appear that way, and in rhinosporidiosis too the same kind of a general scheme of construction is observed. Now there is another parasite, *Histoplasma capsulatum*, which as far as I know has not been thus far reported in the skin and in which the history has been along these same lines; namely, that for a long time the parasite was regarded as a protozoon. Eventually it was cultivated and revealed as a fungus. Dr. DeMonbreun was among the first in this country to accomplish this. I would be pleased if Dr. DeMonbreun is here to have him give his impression of the possibility that the parasite pictured this afternoon is a fungous one. The lesson from this is that, simply because we have failed with ordinary bacteriologic methods to cultivate the parasite of granuloma inguinale is no reason why we should at once jump to the conclusion that it is not cultivable. It is only the method that awaits the cultivation of this micro-organism, and perhaps it is the mycologic one. If the authors have the time, I should like to hear more about the details of the arrangement of the parasite in the cell.

DR. W. A. DEMONBREUN, Nashville, Tenn.: Dr. Goodpasture and I have studied the organism of granuloma inguinale on various mediums. We were also fortunate in having one case in which we got pus from an unruptured lesion but could not cultivate organisms from it. We watched the Donovan bodies degenerate and disappear from the cultures. From other cases we did cultivate a gram-negative bacillus belonging to the *aerogenes* group, but not in primary cultures. We cultured the exudate from the lesions on chorio-allantoic membranes of chick embryos for from three to five days when subcultures from the membranes yielded an unencapsulated gram-negative bacillus on blood agar. After two or three weeks secondary colonies were noted in the colonies and occasionally encapsulated organisms that had the morphology of the Donovan body were found in them. We planted the cultures directly from blood agar into undiluted human serum and sealed the cultures. In eight or ten days we noticed encapsulated forms that went through all the morphologic changes that we observed the Donovan body doing in the lesion. In several instances we also recovered the same organism from the lesions by cultivating the granulomatous tissue in infusion broth. During the first three or four days staphylococci usually grew out in abundance but in four or five days most of these organisms were degenerated, and subcultures on blood agar yielded the organism I have described. By cultivating feces from several of the patients, we obtained the same organism. However, we could not reproduce the disease with the organism, even though we tried to do so in several human volunteers. I think that most physicians who have studied numbers of smears from lesions of granuloma inguinale conclude that the organism goes through a definite cycle, and perhaps the phase of the organism which we succeeded in cultivating is not the pathogenic phase. With regard to the generalized lesions that have been reported in two or three of these cases, I, like Dr. Weidman, would like to know more about the appearance of the organisms in the lesions. In histoplasmosis, which is caused by the fungus *Histoplasma capsulatum*, there is a widespread infection of the reticulo-endothelial cells by this fungus. In sections there is a superficial resemblance of the encapsulated, yeastlike, intracellular forms of the fungus to Donovan bodies and the possibility that the so-called generalized cases of granuloma inguinale are really cases of histoplasmosis should be considered.

DR. ROBERT B. GREENBLATT, Augusta, Ga.: Dr. Robinson quoted the work of Butts, who maintained that in the lesions in all his cases a spirochete was found. That isn't new. Some thirty-five years ago Maitland and Wise, and some years after that Cleland had the idea that spirochete is the causal agent because of the frequency with which it is found in the open lesions of granuloma inguinale. From time to time one investigator or another crops forth with the same idea. I wrote Dr. Butts following the appearance of his article and pointed out that some spirochete or other may be demonstrated in a large percentage of the chronic ulcerations about the genitalia regardless of the etiology of the lesion. Dr. Becker described a case in which systemic manifestations of this disease occurred. This is very interesting and a rare occurrence. There are in

the literature reports by Thierfelder and Thierfelder Thillot of several cases in which visceral abscesses in which Donovan bodies were demonstrated were observed at autopsy. Mayer and da Rocha Lima quote the case of Hoffman and that of Kuhn in which generalization of the disease occurred with involvement of the bones, liver and other visceral organs. I regret that Dr. Schoch has been unable to demonstrate the pathognomonic cell in tissue sections. We have found useful not only well prepared sections stained by hematoxylin and eosin but also sections submitted to the old fashioned Dieterle silver stain. The Donovan bodies are beautifully demonstrated within the cysts of the large mononuclear cells. Dr. Goldblatt remarked that antimony tartrate is unsatisfactory in therapy. The longer we work with this disease the more ready are we to agree with him. We have found many cases respond well to antimony and potassium tartrate or fuadin only to be seen at a later date with a recurrence. The use of sulfanilamide in this disease has proved of no value. We have pointed out in another publication that sulfanilamide has but a limited place in the therapy of venereal lymphogranuloma. Let me state that 50 per cent of the buboes of venereal lymphogranuloma will subside without therapy and they who report such excellent results with this drug are unmindful of the incidence of spontaneous cures. Dr. Weidman's points are well taken. I regret that time did not permit me to dwell on the nature of the Donovan body. It is however more fully handled in the text of this paper. We concur with Dr. Weidman in the contention that the Donovan body is not a bacterium.

THE SILICOSIS HAZARD IN MECHANICAL DENTISTRY

LOUIS E. SILTZBACH, M.D.

WITH THE TECHNICAL ASSISTANCE OF
JACK SIEGEL, CHEMIST
NEW YORK

On the long list of industries known to be associated with the silicosis hazard, mechanical dentistry is not to be found. It is our purpose in this communication to indicate that a silicosis hazard is present in this hitherto unlisted industry and to suggest the steps which may be taken in the elimination of the hazard.

REPORT OF CASE

History.—C. J., a man aged 35, a Russian Jew, employed as a dental technician, was admitted to the Division of Pulmonary Diseases of Montefiore Hospital Nov. 16, 1937. He had been transferred from another hospital, where a diagnosis of pulmonary tuberculosis had been made. His illness commenced in January 1936 when a slightly productive morning cough was noted. This complaint was mild and was ignored. In December the patient remarked that breathlessness was present on moderate exertion. In January 1937 a small hemoptysis occurred and this recurred at irregular intervals thereafter. In April weakness and loss of weight supervened. He sought medical advice and entered a hospital for treatment August 30. At the hospital a diagnosis of chronic bilateral pulmonary tuberculosis was made and the patient was treated with bed rest. The sputum contained tubercle bacilli.

On admission to Montefiore Hospital physical examination revealed that the patient was poorly nourished and had slight dyspnea at rest. There was moderate cyanosis of the lips and nail beds, but clubbing of the fingers was absent. The chest was increased in its anteroposterior diameter. There was dullness and impaired resonance over the upper part of the chest. Harsh bronchovesicular breathing was heard throughout the chest with universal medium, moist rales. Musical rales were heard over the right base posteriorly. The rest of the physical examination elicited no abnormalities.

From the Division of Pulmonary Diseases, Montefiore Hospital, and the Division of Industrial Hygiene, New York State Department of Labor. Drs. Leonard Greenberg, Adelaide Ross Smith and May R. Mayers of the Division of Industrial Hygiene, New York State Department of Labor cooperated with the authors in this work.

Examination.—X-ray films of the chest on admission (fig. 1) showed that both lung fields contained numerous soft nodular densities from apex to base. These nodules varied in size from that of a pea to that of a hazelnut and lay within a meshwork of coarse, strandlike densities. The mediastinal shadows were considerably widened and increased in density. There was a cavity 4 cm. in diameter in the right lower lung field. A fluid level was present within the cavity.

The sputum contained tubercle bacilli. The sedimentation rate of the red cells (Cutler) was 25 mm. at the end of one hour. The blood count showed a slight leukocytosis but the differential count was not abnormal. The Wassermann and Kahn reactions of the blood were negative. A twenty-four hour specimen of urine contained no tubercle bacilli on smear. The vital capacity was 1,850 cc. The circulation time was nine seconds (saccharin) and seven seconds (ether). The venous pressure in both arms was 8.1 cm.

Occupational History.—Because of the suggestive x-ray appearance, additional detailed investigation of the patient's occupation was made: The patient had migrated to America at the age of 8 years and went through the public schools. From the age of 16 until the time of admission to the hospital, i. e. for nineteen years, he worked for the same dental laboratory and performed the same operation without any break in his employment. The patient was the only employee doing this type of work.

His work consisted exclusively of polishing dentures. Because of the large volume of work which the establishment turned out, he was required to polish as many as fifty dentures during an eight hour day. The polishing operation is performed on a cloth wheel which is attached to an electrically driven spindle. The abrasive material, a very finely ground powder known as "pumice," is kept in a small pan situated just below the revolving polishing wheel. Water is added to the powder and the moistened powder is applied to the surfaces and crevices of the dentures to be polished. The denture is held against the revolving wheel with frequently renewed applications of the abrasive until the rough spots in the denture are all smooth. The polishing machine which the patient used was located in a small alcove 30 feet from the nearest window. No suction device or other means of ventilation was provided for the purpose of drawing off the rising dust.

The dust constantly irritated the patient's nose and throat and over the years he took crude precautions against its aspiration. His work clothes consisted of an apron and a skull cap, the latter because he found that his hair, when uncovered, was laden with dust at the end of the day. In summer, particularly, the dust seemed to be more irritating, and the patient would at times wear a wet towel over his nose and mouth. About a year before his incapacity he bought a crude rubber mask but discarded it soon after because he could not breathe through it easily. When his pulmonary symptoms finally appeared he ascribed them to the dusty nature of his work.

This occupational history, associated with the x-ray signs, suggested a tentative clinical diagnosis of silicotuberculosis.

Course.—During his stay at Montefiore Hospital the cough increased and the expectoration became mucopurulent and more copious. The temperature ranged up to 101 F. The cyanosis and dyspnea were more prominent, so that the patient could not walk across the room without extreme breathlessness. April 15, 1938, five months after admission, he had a profuse hemoptysis. He died April 23.

Postmortem Examination.—The lungs were voluminous, and numerous firm areas could be felt throughout (fig. 2).

Right Lung: The visceral pleura was dull and thickened and the pleural cavity was obliterated by adhesions over the upper lobe. A fine fibrinous pleurisy was present over the lower lobe but there was no fluid in the pleural cavity. The lung cut with great difficulty and was almost stony hard in its upper half. The cut surface was grayish black and extremely gritty. Gray-black pigment was most prominent in the airless upper lobe where the fibrosis was most marked. It was difficult to detect any discrete nodules in the upper lobe, but these were present in great profusion, uniformly studding the middle and lower lobes. The nodules were darker than the surround-

ing lung tissue; they were firm, protruded from the surface and varied in dimension from the size of a millet seed to that of a small pea. In the middle lobe these nodules were surrounded by small yellow areas of caseation. The middle lobe contained two large cavities with thin walls which were lined with caseous material. They communicated with the bronchial tree and one of them contained a large blood clot. An eroded pulmonary vein was found in the wall of the cavity. The lower lobe contained areas of caseation and was emphysematous, particularly at its inferior margins.

Left Lung: Except for the absence of tuberculous cavities, this lung presented an appearance essentially similar to that of the right lung. The paratracheal and bronchopulmonary lymph nodes were enlarged to three or four times their normal size. They were stony hard and cut with difficulty. On the cut surface, which was gritty, numerous, gray-black nodules stood out from a black background.

Other abnormalities included hypertrophy of the right ventricle with considerable dilatation of the outflow tract, mild atherosclerosis of the pulmonary artery, chronic passive congestion of the viscera and a few tuberculous ulcers in the ileocecal region.

Microscopic examination from various sections of the lungs revealed the following: In the upper lobes the normal architecture of the pulmonary tissue was almost completely destroyed.

Dense fibrous tissue with anthracotic pigment was seen in its place. No typical silicotic nodules were present in this area. In sections taken from the midlung fields caseation predominated with typical areas of caseous bronchopneumonia. Interspersed among these foci of tuberculosis lay large silicotic nodules with their typical whorls of dense hyalinized fibrous tissue, in the meshes of which lay pigment laden macrophages (fig. 3). The nodules stained deeply red with the Van Gieson stain except in those areas in which the caseation had loosened the hyaline strands within the silicotic nodule. In such nodules the areas adjoining the caseous foci no longer stained deeply red. In the lower fields of the lung numerous typical silicotic nodules, partly coalescing, could be seen with adjoining areas of nonspecific bronchopneumonia.

The postmortem diagnosis was far advanced silicotuberculosis, hypertrophy and dilatation of the right ventricle, chronic passive congestion of the viscera and tuberculous ulcers of the small intestine.

Chemical Analysis: Postmortem samples from various areas of the lungs and lymph nodes were analyzed for content of silica with the results given in table 1.

Fig. 1.—Appearance of chest Dec. 16, 1937: Nodular densities from apex to base, uniformly distributed in both lung fields, lie within a meshwork of strandlike densities. A cavity in the right midlung field with a fluid level is not clearly reproduced. Both hilar shadows are considerably widened and increased in density.

COMMENT

These results run parallel to those of analyses on eight silicotic lungs reported by Sladden.¹ The percentage of total silica of dry lung tissue in his series ranged between 0.6 and 1.0 in cases in which an advanced stage of fibrosis associated with tuberculosis was present.

Our samples of lung tissue yielded a somewhat higher percentage of ash of dry matter than that reported by

1. Sladden, A. F.: The Silica Content of Lungs, *Lancet* 2:123 (July 15) 1933.

McCrae.² Riddell and Rothwell³ report analyses of the lungs of two patients who died of silicotuberculosis in which the total silica of ash of the dried lungs was about 15 per cent, slightly higher than what we found in our samples of lung.

Fig. 2.—Cut section of specimen of lung. Gray-black discoloration of the pulmonary tissue with diffuse fibrosis most prominent in the upper two thirds of the lungs. Silicotic nodules best seen in the lower fields of the lung with small areas of caseation. Enlarged black lymph nodes are seen in the hilar area.

Our patient was allegedly using pumice during the nineteen year span of his polishing work. Pumice, according to analyses made by the U. S. Bureau of Mines,⁴ is a mixture of complex silicates of aluminum, sodium, potassium, calcium, magnesium and iron in approximately the percentages given in table 2.

TABLE 1.—Chemical Analyses of Samples of Lung and Lymph Node

	Lung	Lymph Node
Dry tissue of fixed tissue as received, per cent	30.90	29.50
Ash of dry matter, per cent.....	11.00	11.70
Total silica of ash, per cent.....	10.10	8.10
Total silica of dry tissue, per cent.....	0.91	0.70

This report does not state whether pumice contains free silica. Knowledge of the free silica content of a dust is crucial toward an evaluation of the silicosis producing possibilities of the dust. However, nowhere in the literature could such information be found with reference to pumice. Pumice dust is included in the list of harmful siliceous dusts along with quartz, sand, granite and slate,⁵ but it is not entirely clear in what basis this dust is so included.

The only reference to the noxious effects of pumice dust that could be found appears in a report by DiMattei,⁶ who examined and took chest films of 100 pumice mill workers on the Lipari Islands (the source of 90 per cent of the total amount of the pumice imported into the United States). These mill workers are engaged in grinding the lump pumice into a fine powder and, according to the author, they work in a dense cloud of this dust. X-ray examination revealed

TABLE 2.—Composition of Pumice

Silica (SiO ₂)	72.0%
Alumina (Al ₂ O ₃)	14.0%
Potash and soda (K ₂ O-Na ₂ O)	7.0%
Lime and magnesium (CaO-MgO)	2.5%
Iron oxide (Fe ₂ O ₃ -FeO)	1.0%
Loss on ignition.....	3%-5%

that almost all the workers were suffering from silicosis. DiMattei states that tuberculosis is so common among the islanders that new operatives must constantly be imported from outlying provinces to replace these workers. He attributes the occurrence of silicosis to the prolonged aspiration of the pumice dust and seeks

Fig. 3.—A silicotic nodule in microscopic section showing typical whorls of hyalinized fibrous tissue in whose meshes lie pigment laden macrophages. Hematoxylin and eosin stain.

to support this contention with chemical analyses of the pumice dust which, he states, contains approximately 75 per cent of total silica. Unfortunately he too neglects to make any statement regarding the free silica content of the dust.

4. Hatmaker, P.: Pumice and Pumicite, U. S. Bureau of Mines, information circular 6560.

5. Sayers, R. R.: Harmful Industrial Dusts, Pub. Health Rep. 53: 224 (Feb. 11) 1938.

6. DiMattei, G.: La pneumoconiosi nei lavoratori della pumice e della lava, Atti del X Congresso Nazionale di Medicina del Lavoro, 1932, pp. 546-552.

Dr. W. F. McConnell⁷ of the industrial health section of the Metropolitan Life Insurance Company informs us that no free silica could be found in two specimens of pumice analyzed in his laboratory and that the silica existed only in the combined form of silicates. Since it is generally agreed that silicates, with the exception of asbestos, do not produce classic pneumoconiosis, this discrepancy between DiMattei's clinical observations and the available chemical analyses of pumice could be explained only by an exceptionally wide variation in the free silica content of pumice.

Since pumice is fairly widely used in industry, further investigation of its free silica content as well as of its disease-producing potentialities seems warranted.

A sample of the "pumice" which our patient used was obtained from his dental laboratory and was chemically analyzed. It contained the surprisingly high content of 48 per cent free silica. The reason for this high percentage of free silica was disclosed after an investigation of three concerns selling abrasive materials to the dental laboratories. It was learned that these concerns were selling a less expensive substitute abrasive powder called "pummy," the substance with which our patient was working. "Pummy" has the same composition as silex, being also silica sand but ground to a greater degree of fineness. This relatively new silica-containing substitute abrasive material came into use for dental purposes during the World War, when Italian pumice was difficult to obtain. Pumice and its substitute "pummy" are sold in about equal amounts to the dental laboratories in the New York City area. None of the purchasing agents of three other dental laboratories visited were aware that the substitute "pummy" and not pumice was in use in their shops.

It is not possible to state how extensive is the silicosis hazard among operatives in mechanical dentistry. A survey of the industry is being planned at the present writing by the Division of Industrial Hygiene of the New York State Department of Labor.

It is not often that the presence of an industrial health hazard can be definitely established on the basis of one case. In our dental mechanic none of the usual obfuscations appear to obscure the cause and effect relationship between the specific trade and the specific illness. He never worked at any other trade, never did any other job but that of polishing dentures; the autopsy showed classic silicotuberculosis. The abrasive material used contained a high percentage of free silica and his unventilated workroom environment made possible a concentration of the dust known to produce silicosis in other trades, where similar concentrations are present.

RECOMMENDATIONS FOR INDUSTRIAL CONTROL

To eliminate the silicosis hazard in mechanical dentistry, certain precautionary steps seem indicated:

The pumice substitute "pummy" should be discarded as a dangerous abrasive material and in its place some harmless material should be used. The question of the possible harmfulness of pumice must await further chemical and clinical investigations.

Many dental laboratories have equipped their polishing apparatus with exhaust hoods. Such exhaust hoods should be required universally.

7. McConnell, W. F., Assistant director, Industrial Health Section, Metropolitan Life Insurance Company: Personal communication to the authors.

SUMMARY

1. An instance of silicotuberculosis occurred in a dental mechanic whose only occupation during life consisted of polishing dentures.

2. Pumice, a silicate complex used in polishing dentures, has been widely replaced by a substitute abrasive "pummy" which contains a high percentage of free silica and which is capable of producing silicosis, as in this instance.

575 West End Avenue.

DIAGNOSING MYELOMATOSIS BY COMPLEMENT FIXATION

MOGENS JERSILD, M.D.

COPENHAGEN, DENMARK

Serum from patients with myelomatosis differs from normal serum in various ways. What has chiefly attracted attention is an increase in the serum protein, mainly in the globulin fraction, which alteration is recognizable by means of various so-called lability reactions. This term is understood to mean reactions which express the fact that the normal colloid stability of the serum is disturbed by reason of a preponderance of the large molecular globulins. Increased serum lability may be manifested in many different ways and may interfere in various seroreactions used for diagnosis, the result being unspecific reactions, that is, reactions that do not

express the immunity or the morbid condition which was intended to be demonstrated.

Increased serum lability can be ascertained in many different ways. The addition of salt (half saturation with ammonium sulfate) gives a precipitation greater than normal, i. e. the globulin is increased. The rate of sedimentation is increased, the increased protein content promoting the formation of the erythrocytes into "coin rolls," a phenomenon which can also be observed under the microscope when counting the blood corpuscles. Takata's reaction is positive, mixture with a mercury bichloride solution producing flocculation. The formol-gel reaction is positive, 0.05 cc. of serum coagulating with one drop of solution of formaldehyde. In addition, a number of other reactions are described which express the same change in the serum, an increased globulin content.¹

Consequently, as the serum of patients with myelomatosis often presents an increase in globulins, it is sometimes possible to diagnose the disease by one of the aforesaid reactions.

From the State Serum Institute, Dr. Thorvald Madsen, Chief.
1. Bing, Jens: Acta med. Scandinav. 91: 336, 1937.

A reaction which I have described previously as occurring in myelomatosis² depends on the fact that in many cases of myelomatosis the serum after it has been heated to about 60 C. is able to fix the complement (the anticomplementary property of serum).

By no means all serums from patients with myelomatosis give this reaction. Nevertheless it is of practical importance, as anticomplementary serums now and then are found in the course of routine Wassermann tests. The Serum Institute is thus in a position to draw attention to it. In several cases the reaction has helped in the diagnosis of myelomatosis although there had been only vague general symptoms.

The mechanism of the reaction and the conditions optimal for its performance were described in earlier papers.³ Here they may be summarized:

1. Complement fixation proceeds without the presence of antigen.

two or three years, twenty-seven serums proved to be anticomplementary to a marked degree and on the whole to possess the properties described.

Each of these was heated to eight different temperatures from 54 to 68 C. (table 1) for ten minutes and then titrated. In every case it was thus possible to determine the temperature for the maximum fixation and the coagulation temperature.

Table 1 contains the data on complement fixation with serum 4. The figures represent the degree of hemolysis. One hundred equals total hemolysis, 0 no hemolysis, and the intermediate figures the various percentages. The total volume 0.5 cc. minus the quantity of complement equals the minimum hemolytic dose. Thus the optimum of serum 4 is 58 C. and the fixability 0.000001.

In addition, a determination of the protein content of each serum was made by Kjeldahl's method⁴ and a formol-gel test performed. For every patient particu-

* A minus sign means a negative observation. Two periods indicate that no examination was made. I have previously referred to patients 1, 2, 3, 4, 11, 13, 16, 18 and 19.² Aage Grut (Ugesk. f. læger 100:85, 1938) has referred to patient 9 and H. E. Nielsen (Hospitalstid. 81:549, 1938) to patient 10. Dr. Jens Bing performed some of the protein analyses. Serum from patient 8 was sent by Dr. Jetzer of Basel, Switzerland. Patient 18 died during July 1939, after having been ill for three years, finally complaining over severe pain in the bones.

2. The fixing property occurs only after the serum is heated to about 60 C.; it is totally absent in unheated ("native") serum.

3. There is an optimum for the attainment of the maximum fixability both with temperature and with p_{H} .

4. Fixability is generally more pronounced than is ever the case when one is titrating other complement fixing serums (fixing dose to 0.0000001 cc. of serum).

The anticomplementary serums thus disclose themselves in the course of a complement fixation reaction by the occurrence of fixation in the control tube, where normally there is complete hemolysis. Closer examination thereafter determines whether such serum has the aforesaid characteristics of myelomatosis serum.

In the course of complement fixation tests (Wassermann tests—tests for the gonococcus) during the past

lars were secured of the diagnosis and of the various examinations made to support it.

From table 2 it appears that:

1. Of twenty-seven patients with anticomplementary serum, myelomatosis was verified in thirteen (1-13), the examination of five (14-18) gave very suggestive results and nine (19-27) presented no sign of myelomatosis (nor were they all thoroughly examined for it).

2. All patients for whom the diagnosis of myelomatosis was certain or probable had increased serum globulin, a positive formol-gel reaction and a high sedimentation rate.

3. With anticomplementary serum and no changes in the serum protein the diagnosis of myelomatosis is less probable.

4. Serum from most patients with myelomatosis has a low coagulation temperature (about 60 or 62 C.).

2. Jersild, Mogens: Ugesk. f. læger. 98:583, 1936. Footnotes 3 and 5.
3. Jersild, Mogens: (a) Ztschr. f. Klin. Med. 130:670, 1936.

4. Henriques, V., and Klausen, U.: Biochem. Ztschr. 254:414, 1932.

5. The temperature for the optimum fixability was about 60 C. for both groups of patients.

6. Bence Jones protein was found in the urine of only seven patients.

7. It is known that eighteen of the patients died a relatively short time after their serum was found to be anticomplementary.

Several serums with a fairly high increase in globulin, from patients with myelomatosis and with other diseases, were examined as to anticomplementary property, but the reaction failed even after they were heated to about 60 C.

Accordingly, the anticomplementary property of serum is a phenomenon found more frequently with an increase in globulin but not a regular consequence of it.

In the anticomplementary serums there must be a particularly labile proteinaceous substance of which the character has not been defined. Ultracentrifuging by the Svedberg method did not show Bence Jones protein in such serum, whereas there was a peculiar dissociability on dilution.⁶

SUMMARY

Of twenty-seven patients with anticomplementary serum, thirteen definitely and five probably had myelomatosis. The reaction occurs only after the serum is heated to from 56 to 60 C., and a considerable increase in globulin is often found; the coagulation temperature of the serum is often low.

SIMPLE TACHYCARDIA IN CHILDREN

R. A. LYON, M.D.

AND

LOUISE W. RAUH, M.D.

CINCINNATI

The significance of tachycardia is difficult to determine in children; it may be the result of organic heart disease or of a functional disturbance of little importance. The normal variations in cardiac rate in children extend over wide limits and emotional stimuli readily increase the rate. Occasionally tachycardia which is not associated with infection or heart disease may persist for long periods and be a cause of alarm to both the patient and the physician. Over a period of years we have observed ten children with rapid cardiac rates and we have attempted to discover the possible etiologic factors and the effects of the continued tachycardia on the health and development of these children.

LITERATURE

The literature on the subject of tachycardia, especially in childhood, is meager. Tezner¹ was impressed by the frequency with which tachycardia occurred in a group of 1,965 school children from 6 to 14 years of age. A cardiac rate above 110 a minute was noted in seventy-two, or 3.7 per cent, which was a higher incidence than that for hospitalized children. The initial examination was made when the patient was standing and it was thought possible that this factor together with that of excitement might have had some influence on the heart rate. When, however, the pulse rate was determined with the children in a sitting position the tachycardia persisted and when the children were in reclining positions only three had a reduction in the

rate, so that it appeared unlikely that orthostatic factors caused the rapid rates. Only two of the group of seventy-two patients had evidence of organic heart lesions. The blood pressure varied between 110 and 115 systolic and 70 and 80 diastolic. Sinus arrhythmia was common, but the electrocardiograms were otherwise normal. In response to an exercise test of bending the knees from ten to fifteen times the cardiac rate increased on an average of from ten to fifteen beats a minute and returned to the initial rate within three minutes. Subjective signs of heart disease were absent and gymnasium work was well tolerated. Determinations of the basal metabolic rates were made for three children, and one had a slight elevation above normal. Pressure over the eyeballs usually caused a reduction in the heart rate but no change occurred with pressure of the vagus nerve. Some of the children with tachycardia were of the vasolabile neuropathic type and they appeared asthenic and pale, perspired readily and had frequent complaints of various types. Many other children with these characteristics did not have tachycardia but the author expressed the belief that the heart rates of children are often greatly influenced by hyperactivity and psychic stimulation.

A single instance of tachycardia in a 10 year old girl was reported by Hutinel, Lebée and Testart.² This child had a constant rate of 130 a minute with no other evidence of organic heart disease. She was excitable but slept well and her general health was good. There were no signs of thyroid disease or disturbance of the sympathetic nervous system and the basal metabolic rate was normal. Tachycardia in soldiers during the war of 1914-1918 attracted considerable attention and the subject has been reviewed by Musser,³ Barringer⁴ and Leconte and Tisé.⁵

The normal variations of pulse rate in children and the greater lability in response to excitement make the diagnosis of tachycardia more difficult. Burlage⁶ observed that the average pulse rate of girls 9 years of age was 98.5 a minute and that with advancing age the rate became slower. Between the ages of 12 and 15 years the average rates were from 87.5 to 92.7 a minute. In nonmenstruating girls, the pulse rate was most closely correlated to height, less so to age and least of all to weight. In menstruating girls the rates were most closely correlated to age, less to weight and not at all to height.

In a review of the pulse rates under basal conditions at various age levels Sutliff and Holt⁷ noted that the average pulse rates of girls were higher than those of boys from the age of 10 years onward and that adult levels of from 62 to 69 beats a minute were not reached until the age of 20. The variability of the heart rate was much greater in children than in adults. Lincoln⁸ found that the average heart rates of boys aged from 6 to 12 years were from 86 to 79 a minute when they were in horizontal positions and from 95 to 82 in vertical positions, with standard deviations of from 7.8 to 11.6 in various age groups. The heart rates determined with

the children in horizontal positions were generally from two to five beats faster for girls than for boys of the same age. The greatest differences usually occurred at the age of puberty.

Great variations of pulse rate during the course of a single day have been observed by Sutherland and McMichael.⁹ In a girl 11 years of age they noted that in the early morning when she was asleep the rate was 30 beats a minute slower than in the afternoon when she was enjoying active play. In their opinion the greatest variations of pulse rate occurred in children of nervous and excitable temperaments and in patients with rheumatic fever.

In experimental studies, Stewart and Crawford¹⁰ found that simple tachycardia with a rate of from 250 to 400 a minute induced for one hour by electrical stimulation of the auricles of dogs did not materially change the oxygen saturation or the volume flow of the blood. The size of the heart, as determined by roentgenograms, decreased during this period of induced auricular tachycardia. It was concluded that the efficiency of the heart was as great during periods of such tachycardia as during the time when the heart rate was normal.

OBSERVATIONS

Ten children, all girls but one, with persistent tachycardia but without evidence of cardiac disease or any other specific illness were observed in our cardiac clinics for a period of from one to seven years. These clinics were held during the morning hours and the pulse rates were counted when the children were relaxed and in a recumbent position. Since the children had become accustomed to visiting the clinic and were well acquainted with the personnel, excitement and fear should not have been responsible for the tachycardia. One child was 6 years of age when the symptom was first noted and her heart rate was 140 a minute; the other children were from 10 to 12 years of age when first observed. Persistent pulse rates of 115 or more a minute were considered to be abnormal, although in the majority of instances the rate was from 120 to 140. This group of ten children constitute only 1.3 per cent of the 782 children who have attended the cardiac clinics because of potential or actual heart disease.

The predisposing factors were difficult to determine. Since eight of the nine girls were preadolescent, some temporary imbalance of the endocrine system might be considered as causative. In two instances nervousness and tremor of the extended fingers suggested thyroid disturbance but the basal metabolic rates were only slightly elevated above normal. The tachycardia lasted for several months before and after the onset of menstruation in six girls. The only boy in the group, 11 years of age, became obese while the tachycardia was present but had no other signs of pituitary or thyroid disturbance. Two girls were definitely underweight when first seen. One girl had had scarlet fever about six months before the tachycardia was noted but none of the other patients had had any serious illness within two years before the rapid pulse rate developed. In four instances rheumatic fever, scarlet fever or diphtheria had occurred from two to seven years previously.

A symptom of damage to the heart, other than the tachycardia, occurred in only one case and this was the indefinite one of dyspnea on exertion. The majority of

the children were entirely free from symptoms of any type and had been referred to the clinics because of the tachycardia, which had been detected on routine physical examination.

Examination of the heart gave practically negative results in all cases. Murmurs of little significance, probably functional or accidental, were heard in four instances, but even this abnormality disappeared completely within one or two years. The teleroentgenogram of one child suggested some cardiac enlargement but the roentgenologic and fluoroscopic examinations of the other children showed no abnormalities in cardiac shape and size. The electrocardiograms did not demonstrate any striking peculiarities in any instance.

REPORT OF CASES

CASE 1.—G. O., a white girl aged 11½ years, who had a pulse rate of 130 a minute in the reclining position, had had several attacks of sore throat and occasional shortness of breath on exertion. The heart sounds were normal except for a splitting of the first sound at the apex. A soft systolic murmur was heard at the apex and aortic areas when the patient was first examined, but this disappeared after a few months. There was a slight tremor of the fingers when they were extended, and the thyroid gland was palpable but not enlarged. No other evidence of hyperthyroidism could be found and the basal metabolic rate varied between -17 and +4 per cent at this time. Roentgenograms showed no cardiac enlargement and the electrocardiograms disclosed nothing abnormal except a sharp and bifurcated P wave in lead 2 and an inverted T wave in lead 3.

The pulse rate was from 120 to 160 at numerous examinations during a period of three years and then decreased, being from 90 to 108 for the next four years. During this time the patient grew and developed normally and her nutrition was excellent.

At the age of 13 years her basal metabolic rate was +15 per cent and at 18 years it was +0.5 per cent.

CASE 2.—R. M., a white girl aged 12 years, had been "nervous" for several weeks. Her past history revealed nothing significant except an attack of diphtheria at the age of 5 years. The heart rate was 120 a minute in the reclining position. There were no murmurs, the size of the heart in the teleroentgenograms was normal and the electrocardiograms disclosed nothing abnormal except the sinus tachycardia. There was no evidence of thyroid disease. At the age of 12½ years, five months after her first examination, menstruation began. The pulse rate in the reclining position dropped to 100 within the next three months and varied between 88 and 104 during the next one and one-half years. An electrocardiogram made when the patient was 14½ years of age revealed nothing abnormal except a tendency to right axis deviation.

CASE 3.—H. D., a Negro girl aged 10 years, had a pulse rate of 104 a minute in the reclining position when first examined; this became as rapid as 120 during the following year. No history of previous infections could be obtained. There were some enlargement of the thyroid gland, hoarseness, a slight tremor of the extended fingers and a soft murmur at the apex. The first basal metabolic rate, taken when she was 10 years old, was ±0, and in the following year the rate was +21 per cent. During one and one-half years of observation the symptoms continued in mild form, the murmur disappeared and the child gained weight but the pulse rate persisted at levels from 100 to 120. She is still under observation.

CASE 4.—D. R., a Negro girl aged 12 years, who had been in good health except for an attack of pains in the joints when she was 10 years of age, when she was first seen had a pulse rate of 120 a minute in the reclining position. The heart was otherwise normal and her nutrition was good. On fluoroscopic examination the size and configuration of the heart appeared normal. The electrocardiogram indicated some slurring of the ST segments in leads 1 and 2. There was no clinical evidence of thyroid disturbance but the basal metabolic rate at the age of 12½ years was +19 per cent. On occasions the heart rate became slower for a minute or less but this curious alternation of tachycardia and bradycardia could not be explained. With

9. Sutherland, G. A., and McMichael, J.: Pulse Rate and Range in Health and Disease During Childhood, *Quart. J. Med.* 22: 519-529 (April) 1929.

10. Stewart, H. J., and Crawford, J. H.: Effect of Tachycardia on the Blood Flow in Dogs, *J. Clin. Investigation* 3: 449-463 (Dec.) 1926; Effect of Regular and Irregular Tachycardias on the Size of the Heart, *ibid.* 3: 483-490 (Feb.) 1927.

the onset of menstruation one year later the patient's heart rate became somewhat slower but was still 108 in both reclining and standing positions.

CASE 5.—R. R., a white girl aged 10 years, who had had scarlet fever at the age of 5 years but otherwise had been in good health, had a pulse rate in the reclining position of 102 a minute and a blood pressure of 140 systolic, 70 diastolic. The pulse rate subsequently rose to 120. An inconstant murmur heard at the base of the heart was considered to be functional. The electrocardiogram was normal. The basal metabolic rate at the age of 11 years was +6 per cent. During a period of observation of four years the pulse rate varied between 94 and 120. Menstruation began at the age of 14 years and after that time the heart rate declined to a maximum of 94 in the reclining position and the blood pressure to 124 systolic, 68 diastolic.

CASE 6.—H. H., a white girl aged 12 years, who had been told by her family physician at the age of 11 years that she had a rapid heart rate, had a pulse rate in the reclining position of 132 a minute but an otherwise normal heart. There was no history of important infection. The electrocardiogram showed a T wave of low amplitude in lead 2 and an inverted T wave in lead 3. The basal metabolic rate was -2.7 per cent. During a period of observation of one year the pulse rate was from 120 to 136, and she is still under observation.

CASE 7.—T. H., a white boy aged 11 years, who had had epistaxis and pains in the joints at the age of 6 years and occasional very mild arthritic attacks since that time, had a pulse rate of 116 a minute in the reclining position and an otherwise normal heart. In the teleroentgenogram the heart seemed to have a rather straight left border but fluoroscopic examination did not demonstrate any abnormality of size or configuration. Electrocardiograms disclosed nothing abnormal, and the basal metabolic rate was -8 per cent. His nutrition was excellent and within the next four years he gained an excessive amount of weight and became somewhat obese. At the age of 12 and 13 years he was from 19 to 23 per cent above the expected weight for his height and age. In the next two years his weight was only from 10 to 14 per cent above average. The heart rate continued between 110 and 120 for about three years after he was first seen but finally decreased to 80.

CASE 8.—D. V., a white girl aged 11 years, had a heart rate of 120 a minute in the reclining position when first seen, about six months after an attack of scarlet fever. Auscultation of the heart gave normal results, and teleroentgenograms showed no abnormalities. Electrocardiograms disclosed nothing abnormal except inversion of the T waves in lead 3. The basal metabolic rate was -11 per cent. The high pulse rate continued for several months but by the end of one year the rate was from 76 to 94 and it remained within normal limits through the succeeding two years of observation.

CASE 9.—P. F., a white girl aged 10 years, had a pulse rate of 132 a minute in the reclining position. Her medical history was irrelevant. The heart appeared normal on auscultation and fluoroscopic examination. In the electrocardiogram the T and P waves in lead 3 were inverted. Her nutrition was below average. The pulse rate slowly decreased to an average of 105 over a period of three years and her nutrition improved.

CASE 10.—E. F., a white girl aged 6½ years, had a pulse rate of 140 a minute in the reclining position. There was no history of important illness. An inconstant murmur was audible at the apical region for about one year. The teleroentgenogram suggested a slight enlargement of the transverse ventricular diameter, and on the electrocardiogram the ST segments in leads 1 and 2 were somewhat slurred. The nutrition was poor. The tachycardia persisted for two years. The patient was in the hospital for observation for one week during this time and the pulse rate in bed was between 100 and 120. A slight elevation of temperature at this time could not be explained. The tuberculin tests and chest plates disclosed nothing abnormal. The basal metabolic rate was +5 per cent.

COMMENT

The treatment prescribed for these children was adequate rest, usually for eleven or twelve hours during each twenty-four hour period. As a precautionary

measure the more vigorous competitive sports, such as swimming, racing and basket ball, were prohibited until it was certain from repeated observations and tests that the rapid heart rate was not the result of organic heart disease. Other children, not included in this report, who had only initial symptoms of tachycardia, soon lost these symptoms when elements of fear and excitement were removed. In the group in which the heart rate remained high, the temporary changes associated with adolescence seemed to be possible etiologic factors in many instances.

SUMMARY

Of ten children with persistent sinus tachycardia and without any evidence of infection or organic heart disease, eight were girls from 10 to 12 years of age and one was a girl of 6 years. Associated with the tachycardia were possible symptoms of mild thyroid disease in two girls, the onset of menstruation in six, and malnutrition in two. The one boy in the series was obese. Repeated observation of these children was necessary to make sure that the tachycardia was not a temporary emotional response and that it was not due to organic disease. During periods of from one to seven years these children had no signs of circulatory failure, and the heart rate frequently returned to normal levels with advancing age.

From observation of these children over a period of years it can be concluded that the tachycardia did not impede normal growth and nutrition, that it did not produce subjective symptoms of any importance and that it tended to disappear within a few years.

Clinical Notes, Suggestions and New Instruments

INFUENZAL MENINGITIS WITH BACTEREMIA TREATED WITH SULFAPYRIDINE: RECOVERY

TOM R. HAMILTON, M.D., AND FRANK C. NEFF, M.D., KANSAS CITY

During the period of clinical trial of Dagenan¹ at the University of Kansas Hospitals a 2 year old girl with meningitis was sent into the children's department by the family physician² for assistance in identifying the type of organisms which he had found in the spinal fluid. With a cell count of 5,000 per cubic millimeter and many organisms visible on the stained slide, the physician found it difficult to identify the various forms which were present but thought that they might be pneumococci and hoped that they might be amenable to serum treatment. We report the case with the rationale of the diagnosis and its treatment with sulfapyridine. In the absence of any known specific therapy we had hoped that this drug might be effective in what we found to be influenzal meningitis with bacteremia.

REPORT OF CASE

Phyllis B., aged 2 years, was observed by the family physician on March 5, 1939, to have symptoms of illness which had developed during the previous night; these were vomiting, high fever, stupor and difficulty of awakening. The temperature was 103 F. and the respiratory rate 72 per minute. Prostration was so severe that the child was not disturbed by the examination. A moderate stiffness of the neck was found, but pneumonia seemed undoubtedly to be localized in a restricted area about 6 cm. in diameter, which suggested that pneumonia with meningismus would explain the illness.

From the Departments of Pathology and Pediatrics, the School of Medicine, University of Kansas, Kansas City, Kan.

1. Sulfapyridine (Dagenan) was furnished for clinical investigation by Merck & Co.

2. The referring physician is Dr. H. M. Benning, Waverly, Kan. As soon as convalescence seemed certain, the girl was sent back from the hospital to her home in Waverly, where he concluded the treatment with the drug.

The next day the chest was clear but the neck was rigid and the Kernig sign was present; a spinal tap yielded cloudy fluid, a cell count of 5,000, mostly polymorphonuclear leukocytes and abundant micro-organisms.

The child was then transported 100 miles in an automobile and admitted to the University of Kansas Hospitals March 7. There were high fever, prostration, opisthotonos, cervical rigidity and positive Kernig and Brudzinski signs. A spinal puncture was performed at once, yielding a peculiar flaky, ground-glass fluid, smears of which showed numerous cells, of which 87 per cent were polymorphonuclear and many micro-organisms of gram-negative, pleomorphic bacillary forms. The spinal fluid sugar was 9 mg. and the globulin test was positive. A blood culture was taken soon after the spinal puncture.

Fewer of the same organisms were seen on smears of spinal fluid drawn on the second hospital day, at which time the cell count was 35,000 with 96 per cent polymorphonuclear leukocytes.

The patient appeared to be much better on the fourth day, at which time the temperature remained below 100. The patient was dismissed March 13, apparently well clinically except for slight fever of 100.4 F. on the seventh hospital day (the ninth day of the illness).

COMMENT

We knew of no published report of this type of meningitis in which treatment with sulfapyridine had been successful, but it seemed advisable to try it, especially since serum therapy offered little benefit. Barnett and Hartmann and their co-workers³ mentioned two fatal cases of influenzal meningitis in which this drug had been used but gave no details.

The accompanying table shows the clinical and laboratory data under hospitalization, with the bacteriologic changes and sulfapyridine dosage.

The diagnosis of *Haemophilus influenzae* was made on the following facts: (1) the pleomorphic type of gram-negative bacilli on direct smears of spinal fluid; (2) the dew drop type of colony growing delicately and yielding the same organisms; (3) the fastidious growth with quick death of some cultures; (4) the production of indole.

Clinical and Laboratory Data

Hospital day.....	1	2	3	4	5	6	7
Blood count.....							
Hemoglobin.....	83%	80%	80%	80%
Red blood cells, millions.....	4.9	4.7	4.3	4.2

Blood transfusion.....	60 cc.	60 cc.

The etiologic relationship of the organism to the meningitis is based on (1) the positive smears and cultures of two consecutive spinal fluids at the height of the disease, which became negative with improvement; (2) the spinal fluid sugar of 9 mg. on admission, rising to a normal of 55 mg. on dismissal; (3) the blood culture on admission yielding the same organism, and (4) the indole production by the organism.

The efficacy of sulfapyridine is suggested by the prompt recovery simultaneously from the clinical and the laboratory standpoint, without the use of specific serum. This is similar to the

response of Teggart's⁴ case with soluseptasine (a May and Baker preparation of the sulfonamide series) without serum.

The mortality rate of 96.4 per cent for influenzal meningitis was given by Neal and her associates⁵ in 1934. A rate of 72 per cent was found by Silverthorne, Fraser and Snelling⁶ from 1930 to 1937, using intrathecal anti-influenzal horse serum and guinea pig complement.

Temperature curve and daily amounts of sulfapyridine. On the eighth and ninth days of the disease the administration of sulfapyridine was interrupted because of the disappearance of organisms from the spinal fluid, the well-being of the child and the falling of the temperature; the child was sent home from the hospital with a quantity of sulfapyridine to be used if necessary. When she reached home a relapse in the fever occurred, so the drug was again used until the temperature dropped to normal on the fifteenth day of the disease and within two days thereafter remained constant at the normal level.

Sulfanilamide was shown by Long and Bliss⁷ to be effective in inhibiting *Haemophilus influenzae* in vitro in a concentration of 1:10,000.

Prontosil alone was able to lower slightly the mortality of mice injected with *Haemophilus influenzae*, while immune serum alone could not lower it satisfactorily, whereas immune serum plus prontosil lowered it to from 13 to 33 per cent, according to Povitsky.⁸

Serum and sulfanilamide in influenzal meningitis have been advocated by Neal and Appelbaum.⁵ Young and Moore⁹ report a case cured by serum and sulfanilamide, although culture of the spinal fluid was positive as late as the thirty-first day, and the patient was hospitalized for forty-five days with an elevated temperature.

We are aware that filtrable virus is a possibility in the etiology of influenzal infections, although not necessarily in meningitis. It was concluded by B  cl  re¹⁰ in the analysis of the Leningrad work of 1936 that clinical symptoms are to be attributed to the toxins of Pfeiffer's bacillus alone. Moderate leukocytosis was noted in the series reported.

Chemotherapy, in any event, is none the less logical in this condition, and one might cite the work of Dochez and Slanetz.¹¹

who treated experimental and spontaneous distemper virus disease, with the conclusion that sodium sulfanilyl sulfanilate seems to be the first chemical agent with definite therapeutic action on filtrable virus infection. They felt that its range of activity in virus disease is yet to be explored. One of us (T. R. H.) has treated a dog which appeared to have distemper, at the Hixon Laboratory, with sulfapyridine, 2 Gm. daily for five days. The dog was much improved in less than twenty-four hours and seemed normal in four days.

A broad concept of general immunity was offered by Locke¹² based on fitness ratings which give an index of the capacity for resistance, obtained from studies on rabbits and man. Among animals with experimental pneumococcal infection treated with sulfanilamide in the low rating group, 25 per cent recovered without supportive treatment and 100 per cent (in a small series) when supported by vitamin B₁ or liver extract. The correlation of this with the influenzal study is that the basis of lowered resistance in Locke's¹² study in man was frequency of the common cold. Those with lower ratings showed a marked susceptibility and those with high ratings a relative immunity.

Any superiority of sulfapyridine in its effectiveness over sulfanilamide in pneumococcal and possibly influenzal infection of the meninges must be in the addition of pyridine, which is the chemical difference between the two drugs.

Pyridine is of special interest because of its close relationship to the vitamin B group. The speed of action of sulfapyridine is in keeping with the rapid penetration through the body of pyridine in acidified form as nicotinic acid.¹³

The mode of action of sulfapyridine in influenzal infection is unfortunately highly speculative and inferential.

The patient studied became afebrile on the sixteenth day of illness, during which time sulfapyridine had been used in somewhat larger doses at first and finally in about 0.5 Gm. doses daily. Recovery has been complete without sequelae.

PREVENTION OF USUAL SYMPTOMS FOLLOWING ENCEPHALOGRAPHY BY THE PRELIMINARY INJECTION OF ATROPINE SULFATE

MICHAEL SCOTT, M.D., PHILADELPHIA

Assistant Professor of Neurosurgery, Temple University Hospital and School of Medicine

Harvey Cushing¹ reported that when he injected 1 cc. of solution of posterior pituitary into the ventricles of a human brain the patient exhibited intense flushing of the face, profuse perspiration, retching and vomiting, salivation and a marked fall in the body temperature. Cushing was able to prevent these reactions by the injection of 1 mg. of atropine sulfate subcutaneously.

It was realized that many of the symptoms during and following the procedure of encephalography were remarkably similar to those produced by Cushing in the manner stated. Accordingly in 1937 my associates and I began the routine use of atropine sulfate before encephalography² and since then we have used one-fiftieth grain (1.3 mg.) with gratifying results in more than 100 encephalograms made of patients with epilepsy and other neurologic conditions.

METHOD

The night before encephalography the adults are given 10 grains (0.6 Gm.) of chloral hydrate and from 20 to 30 grains (1.3 to 2 Gm.) of sodium bromide. On the morning of encephalography the same dose is given, and one-half hour before injection of air 2 grains (0.13 Gm.) of soluble phenobarbital is given by hypodermic. In place of the phenobarbital we may

use a 50 milligram scale of tribromethanol in amylene hydrate by rectum. Morphine and its derivatives are not used because of respiratory depression. Fifteen minutes before the injection of the air one-fiftieth grain (1.3 mg.) of atropine sulfate is given subcutaneously. Children receive the same hypnotics in doses compatible with age. Those above 5 years of age are given $\frac{1}{100}$ grain (0.65 mg.) of atropine sulfate. We have not used it in infants because of the uncertain effects of large doses.

CONCLUSION

In more than 100 cases we have found that the subcutaneous injection of $\frac{1}{50}$ grain (1.3 mg.) of atropine sulfate about fifteen minutes before starting encephalography will decrease considerably such symptoms as excessive perspiration, nausea and vomiting, and headache. This amelioration of symptoms is seen not only during the procedure but also during the post-injection convalescent period.

Special Article

THE PHARMACOPEIA AND THE PHYSICIAN

WHEN ARE DRUGS USEFUL IN PULMONARY TUBERCULOSIS?

ALLAN J. HRUBY, M.D.

Secretary, Board of Directors, City of Chicago Municipal Tuberculosis Sanitarium; Member of Attending Staff, Tuberculosis Department, Cook County Hospital

CHICAGO

This is one of the second series of articles written by eminent authorities for the purpose of extending information concerning the official medicines. The twenty-four articles in this series have been planned and developed through the cooperation of the U. S. Pharmacopoeial Committee of Revision and THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION.—ED.

Drug therapy in pulmonary tuberculosis embraces three distinct fields: (a) the treatment of symptoms, (b) the treatment of complications and (c) the treatment of associated diseases.

The treatment of the complications and associated diseases leads into every province of medicine. To meet the indications as they arise, the sanatorium of today has become a highly specialized institution with a staff of visiting consultants capable of treating competently all nontuberculous conditions, surgical and medical, that afflict the consumptive in addition to the "primary malady."

TREATMENT DIRECTED AGAINST THE CAUSE

Prophylaxis centers largely, if not entirely, on control of the open case and includes such measures as separation of the contact child, collapse therapy, the compulsory report, school surveys to detect the primary source of infection, legislative measures directed both toward control in the human being and such coercive legislation as exemplified by pasteurization ordinances, score card inspection of dairies and tuberculin testing of cattle.

In prophylaxis too one has to consider, and consider seriously, the BCG vaccine, which, although it has found general application and favor abroad, has as yet not reached far beyond the borders of research in this country.

Apart from the possibilities of BCG and the mechanical specificity of collapse therapy, at present there is

no specific drug or vaccine for tuberculosis. Vaccines and tuberculins used in the past have been discontinued, largely because of the unsatisfactory results and danger of the severe local, focal or general reactions that tend to activate the disease and cause further dissemination.

Why is a specific agent still lacking? There is still a great void in our knowledge of the immunologic questions inherent in tuberculosis. The literature on the subject is all confusion, an array of controversial opinion largely due to failure to make a distinction between tuberculous infection and tuberculous disease. Tuberculous infection implies tissue reaction, namely tubercle formation brought about by implantation of the bacillus. Disease means growth and spread from the primary focus, bacillary activation accompanied by symptoms of absorption and the elaboration of such toxins as the tubercle bacillus forms through its metabolism in the tissues.

The reaction to the bacillus is uniform. There is no known immunity to infection. The constancy of this is seen in animals which are refractory to tuberculosis and rarely develop disease under natural conditions. Such animals show tubercle on inoculation; tubercle, it is true, that is usually nonprogressive. It is on this fact—constancy of reaction with variability in sequence—that Calmette and Guérin based their vaccine, a culture of bovine bacilli many generations old of markedly attenuated virulence but still alive. Attempts to produce immunity with dead bacilli had been tried many times but found to be without avail. Though the dead organisms did produce the specific tissue reaction, namely tubercle, they exercised no influence on immunity.

TREATMENT DIRECTED AGAINST THE PATHOLOGIC CONDITION

As far as is known, there is no medicine that acts directly on the tubercle bacillus in vivo or uniformly increases the defense reaction of the body. Henrichsen and Sweany¹ have experienced favorable results using gold sodium thiosulfate in approximately 50 per cent of cases of advanced tuberculosis with a stationary or progressive trend. Similar results have been reported by others. At the International Tuberculosis Congress at The Hague in 1932 the discussion on the subject seemed largely favorable.

Much, however, remains to be done with gold sodium thiosulfate. For the present it is admitted that the pathologic lesions are best controlled by collapse therapy, a measure which, from the mechanical standpoint, may be considered specific. Collapse therapy meets the prime indication—rest, a chapter in the treatment of tuberculosis which collapse has modified and confined.

THERAPY DIRECTED AT THE SYMPTOMS

Fresh air, good food, high caloric, high mineral and high vitamin diets stressing vitamins A, B, C and D, sunshine, heliotherapy for extrapulmonary lesions, postural change for drainage of cavities, rest in its various implications, complete bed rest, localized immobility through the medium of shot bags, corsets and other nonmedicinal or surgical procedures, psychic rest as well as physical, occupational therapy and other measures designed to complement rest of the body by promoting repose of the mind—this constitutes routine therapy.

I think of the pharmacologic action of drugs in tuberculosis according to the following classification:

1. Drugs that exercise their action by their elimination through the lungs, namely creosote and guaiacol.
2. Drugs that supposedly tend to influence fibrosis or stimulate the defense reaction of the body (e. g. gold sodium thiosulfate, still in the research stage, as described).
3. Drugs with a general tonic or alterative effect.
4. Drugs that have an action on the sympathetic nervous system.
5. Drugs acting on the demineralization theory of tuberculosis, such as calcium.

Drugs Eliminated by the Lungs.—In this group come creosote and its derivatives guaiacol, guaiacol carbonate, creosote carbonate, thiocol, guaiatonic, guaiacose and proposote. Regarding their action, Nammack and Tiber² state that guaiacol is not eliminated by the lungs if taken by mouth and have in consequence advised the intravenous method of administration. As a group, these drugs act on the bronchial secretion, diminish the amount of sputum and produce a change in its character, rendering it less purulent. In their work Nammack and Tiber confined themselves to pulmonary abscesses. It would seem reasonable to suppose however that, owing to their action on bronchial secretions, these drugs would help to clean up the bronchitis, bronchiectasis or abscesses frequently associated with tuberculosis, conditions often underlying the so-called protracted colds of the tuberculous patient.

Notwithstanding these results, substantiated by others, the Council on Pharmacy and Chemistry³ announces that creosote and guaiacol have been omitted from New and Nonofficial Remedies. From the standpoint of specific or chemotherapeutic action the omission is perhaps justifiable; practically, however, these drugs most certainly appear to have a definite clinical value in the treatment of cough and sputum. It is necessary to remember, however, that they may be disturbing to the digestion.

Drugs That Tend to Influence Fibrosis.—The copper salts once thought effective in this respect and gold in its various combinations have been investigated and found wanting. Colloidal preparations of copper, gold and silver subcutaneously or intravenously are still being investigated, especially the gold sodium thiosulfate or sanocrysin of Möllgaard. Caution is indicated and over-enthusiasm must be guarded against. The metallic substances produce an inflammatory reaction around the focus of disease much as does tuberculin. In the use of any metal in therapy, the physician may encounter a toxic action of the heavy metal in stomatitis, enterocolitis, dermatitis, nephritis or neuritis.

Drugs with a General Tonic or Alterative Effect.—In this class comes cod liver oil, the value of which lies in the vitamin and high fat content; fruit juices, and concentrated vitamin C.

Drugs That Have an Action on the Sympathetic Nervous System.—Iodine has its normal concentration highest in blood and is eliminated through the kidneys. In cases benefited by the use of iodine, I believe the improvement is due not to its chemotherapeutic value but to its action on the sympathetic nervous system, much in the same way that compound solution of iodine influences toxic goiter.

2. Nammack, C. H., and Tiber, A. M.: The Treatment of Lung Abscess by Means of Guaiacol Intravenously, *J. A. M. A.* 109:339 (July 31) 1937.
3. Guaiacol and Creosote Compounds, Reports of the Council on Pharmacy and Chemistry, *J. A. M. A.* 110:209 (Jan. 15) 1938.

1. Henrichsen, K. J., and Sweany, H. C.: Sanocrysin Treatment in Tuberculosis, *Am. Rev. Tuberc. (supp.)* 25:1 (Oct.) 1933.

In my experience the best results are seen in the sympathicotonic tuberculous individual with an acute condition presenting dilated or irregular pupils, flushed face, sweating, rapid pulse, tremor and anxious expression; in other words, the case simulating toxic goiter.

Results today are measured by the pathologic lesion as shown on x-ray examination and not, as in the past, by the yardstick of a clinical improvement which only too often meant nothing more than a temporary lessening of the toxemia and the swing of the clinical classification from C to A. The "repeaters" to the sanatorium were much more frequent in those days than they are today, when improvement in the lesion is charted by the x-ray examination and the extent of collapse.

Drugs Acting on the Demineralization Theory of Tuberculosis.—Those who adhere to a demineralization theory in tuberculosis administer calcium gluconate and calcium lactate, from 30 to 60 grains (2 to 4 Gm.) a day. Clinically, however, there is no evidence of loss of calcium, and calculations of blood calcium remain quite normal in the disease.

TREATMENT OF SYMPTOMS

Collapse therapy has taken the place of many of our old time drugs. The symptoms and physical abnormalities in pulmonary tuberculosis are many and the pathologic lesions diverse, including frequently in the same pulmonary lobule a simultaneous patchwork of exudation, caseation, ulceration, fibrosis and calcification. To meet such protean indications in full detail would strain half the pharmacopeia. I shall confine myself to the management of a few cardinal symptoms, including (a) symptoms of tissue destruction, (b) symptoms of toxemia and (c) symptoms of reflex origin as classified by Dr. Francis Pottenger.

Hemorrhage.—This subject is too vast to be handled in a few lines. I refer the reader to "The Therapy of Hemoptysis" by Dr. Bernard Fantus, director of Therapeutics of the Cook County Hospital, and Dr. Frederick Tice, president of the board of directors of the City of Chicago Municipal Tuberculosis Sanitarium, in *THE JOURNAL*.⁴ However, it is necessary to emphasize the warning of Fantus and Tice on the indiscriminate use of morphine in the treatment of hemorrhage. Morphine, by decreasing the reflexes and abolishing the cough, tends to retain the secretions.

Cough.—The cause should be carefully determined. Cough is a physiologic response to irritation in either the lower or the upper respiratory system, including the nose, throat and bronchi. It may be of reflex origin due to pleurisy, pressure of mediastinal glands, mediastinal displacement, inflammation and foreign bodies in the ear, throat and the like.

Naturally the treatment will depend on the cause. When due to inflammation in the respiratory tract it performs a useful purpose in eliminating the irritative material, namely sputum, and should not be lessened unless excessive. It can be managed, however. The patient should cough with the glottis open in order to avoid stress, strain and excessive intrapleural and pulmonary pressures. He should restrain his cough until there is a sufficient amount of secretion collected to make the act productive. To prevent strain by gagging, hot water or milk is useful, aided by ammonium chloride or ammonium carbonate in suitable prescriptions. These expectorants are useful when the sputum is

excessive or is associated with postural drainage in the presence of bronchiectasis. They may be given as in prescriptions 1 and 2.

PRESCRIPTION 1.—*Ammonium Chloride*

	Gm. or Cc.
Ammonium chloride	10
Syrup of glycyrrhiza	120
Mix and label: Teaspoonful in a half glassful of water every two hours.	

PRESCRIPTION 2.—*Ammonium Carbonate*

	Gm. or Cc.
Ammonium carbonate	5
Distilled water	20
Syrup of acacia	60
Syrup of glycyrrhiza	to make 120
Mix and label: Two teaspoonfuls in a half glassful of water every two hours.	

For the dry, useless cough caused by the reflex irritation from pleurisy, mediastinal pathologic change or irritation in the upper respiratory tract, voluntary suppression of the cough is aided by avoiding the use of tobacco and exposure to smoke, dust and irritating gases. Another effective measure is the use of soothing lozenges (slippery elm lozenges or licorice gum drops). If this does not suffice, one may have to take recourse to codeine (prescriptions 3 and 4).

PRESCRIPTION 3.—*Codeine*

	Gm. or Cc.
Codeine phosphate	0.25
Distilled water	4.00
Aromatic syrup of eriodictyon	to make 120.00
Mix and label: Teaspoonful in a little water every two hours as required.	

PRESCRIPTION 4.—*Codeine in Sugarless Vehicle**

	Gm. or Cc.
Codeine phosphate	0.25
Saccharin	0.015
Glycerin	2.00
Peppermint water	to make 60.00
Mix and label: Teaspoonful in water every two to four hours as required (for associated diabetes).	
* Elixir of terpin hydrate and creosote (without sugar) is also satisfactory.	

Other effective measures include hot water or milk, throat sprays (Dobell's solution) or inhalants.

PRESCRIPTION 5.—*Creosote Inhalant*

	Gm. or Cc.
Menthol	0.50
Creosote, Chloroform, each in sufficient quantity	to make 30.00
Mix and label: Inhale by putting a few drops on a "chloroform mask."	

PRESCRIPTION 6.—*Steam Inhalant*

Tincture of benzoin	60 cc.
Label: Teaspoonful in one-half pint of hot steaming water and inhale every three hours.	

Sedative cough mixtures are often necessary but, as a rule, heavy doses of opiates are to be avoided. Morphine and pantopon are seldom necessary in treating a tuberculous cough unless the disease is associated with cancer, in which event these drugs are of little value.

For treating a cough in diabetes, prescription 4 is effective and safe.

Dyspnea.—In ordinary, uncomplicated tuberculosis, dyspnea is rarely severe enough to necessitate special treatment. When severe, it is usually caused by such

PRESCRIPTION 7.—*Digitalis*

Digitalis	2 Gm.
Divide into twenty capsules.	
Label: One every four hours.	

sequelae to pulmonary tuberculosis as a degenerated myocardium. Myocardial failure is evident in the cardinal syndrome of cyanosis, dyspnea, pulmonary congestion, especially posterior and basal, aggravated cough and peripheral venous dilatation.

⁴ Fantus, Bernard, in collaboration with Tice, Frederick: The Therapy of Hemoptysis, *J. A. M. A.* 110: 579 (Feb. 19) 1938.

For peripheral vascular failure, accompanied by low blood pressure, pallor, irregular and feeble pulse, poor heart sounds, extreme weakness and sweating, digitalis (prescription 7) may be of help.

Inhalations of oxygen through a nasal catheter or the oxygen tent may be indicated.

In the presence of dyspnea due to marked peribronchial or pleural fibrosis associated with bronchitis, bronchiectasis or compensatory emphysema, there is little to be done medically except to meet the indications as well as can be by fresh air or inhalations of oxygen.

For asthmatic dyspnea or an associated asthma, I use prescription 8. Great care must be taken in the use

PREScription 8.—*Antispasmodic Expectorant*

	Gm. or Cc.
Potassium iodide	8
Ammonium chloride	10
Fluidextract of lobelia,	
Fluidextract of belladonna, of each.....	2
Tincture of hyoscyamus.....	16
Syrup of glycyrrhiza.....in sufficient quantity to make	120

of potassium iodide in tuberculosis, since the drug holds possibilities of harm.

If the antispasmodic expectorant given does not succeed, solution of epinephrine (from 0.5 to 1 cc.) should be given intramuscularly. Ephedrine with phenobarbital (prescription 9) should be given at the same time to prolong the effect.

PREScription 9.—*Ephedrine with Phenobarbital*

	Gm.
Ephedrine sulfate	0.75
Phenobarbital	1.50
Mix and divide into fifteen capsules.	
Label: One every two hours as required.	
Epinephrine	1:1,000 ampule as required.

Pain.—Pain, a manifestation of reflex action, is usually situated about the upper part of the chest and shoulder girdle, and rarely needs specific attention but may sometimes be relieved by a mustard plaster applied for fifteen minutes. When severe, lancinating and due to a dry pleurisy, aminopyrine (0.3 Gm. tablets) every two to four hours may give relief. If not, the combination analgesic presented in prescription 10 will usually succeed.

PREScription 10.—*Compound Analgesic Capsules*

	Gm.
Codine phosphate	0.25
Caffeine citrate	0.50
Acetylsalicylic acid	3.00
Acetophenetidin	3.00
Mix and divide into fifteen capsules.	
Label: One every four hours as required.	

Fever.—Fever is due to the absorption of the bacillary metabolic toxins or to an associated infection with other organisms. As a rule the indication is met adequately by nonmedicinal measures, including absolute rest, collapse therapy, baths and sponges, and plenty of carbohydrates in the form of fruit juices. Antipyretic drugs are contraindicated in the advanced, critical, terminal case. Occasionally, when the fever is high, owing to associated causes or in the early stages of the disease, they may be indicated.

PREScription 11.—*Antipyretic*

	Gm.
Acetylsalicylic acid	10
Calcium gluconate	15
Divide into ten powders.	
Label: One every four hours as required.	

Citrated caffeine, 0.03 Gm. or more, may be added to prescription 11 if the patient seems in need of stimulation.

Night Sweats.—Night sweats are a reaction due to the dropping of the body temperature in the early morning hours. Drugs are of little value and the symptom is best controlled by nonmedicinal measures.

Insomnia.—This is often caused by pain, cough, night sweats and dyspnea. The treatment of the symptom is the treatment of the cause. When due to nervousness, insomnia may be controlled by nonmedicinal measures such as plenty of fresh air, sponging, light massage and a cup of hot milk or chocolate with a few cookies before bedtime. In the severer cases bromide (prescription 12) may suffice. If it does not, the addition of phenobarbital to bromide (prescription 13) may suffice. If this fails, tablets of phenobarbital (0.10 Gm.) may have to be resorted to.

PREScription 12.—*Bromide*

	Gm. or Cc.
Potassium bromide	30
Distilled water	30
Syrup of glycyrrhiza.....	sufficient to make 120

Mix and label: Teaspoonful in milk at bedtime or after supper and at bedtime.

PREScription 13.—*Bromide and Phenobarbital*

	Gm. or Cc.
Potassium bromide	10
Elixir of phenobarbital.....	to make 60

Mix and label: Teaspoonful in water at bedtime, repeated every two hours as required.

Improving Nutrition.—It must be pointed out, however, that anything which improves general nutrition helps to increase the defense reaction, and that anything which favors rest favors healing. To the extent to which medicines can be used to improve nutrition they are second only in importance to diet; to the extent to which they favor repose, both physical and mental, they may be used to reinforce the great curative principle of rest. Among drugs that may improve nutrition when they are properly used may be mentioned cod liver oil, iron and arsenic, the bitter stomachics and possibly iodine. The value of cod liver oil ranks high not only because of its vitamins but also because of its high fat content. It may be prescribed in the form of its official emulsion (prescription 14) or as the aromatic cod liver oil (prescription 15).

PREScription 14.—*Cod Liver Oil, 50 Per Cent*

Emulsion of cod liver oil..... 250 cc.
Label: Teaspoonful to a tablespoonful in a little water two hours after meals.

PREScription 15.—*Cod Liver Oil*

	Gm. or Cc.
Saccharin	0.25
Compound spirit of orange.....	10.00
Cod liver oil.....	to make 500.00

Mixed and label: Teaspoonful to a tablespoonful two hours after meals.

A patient who takes and digests well an abundance of eggs, cream and butter may not need cod liver oil; his anemia, however, may be benefited by iron (prescription 16) or by iron combined with arsenic (prescription 17). As was the case with creosote, it must be

Tuberculosis is not readily accessible to medicinal measures. The chief stumbling block lies in the fact that it is difficult or impossible to get to the pathologic condition. Thrombosis of the blood vessels, shutting off the circulation to the tubercle, forms a barrier against drugs, a barrier further reinforced by the natural defenses to foreign body intrusion, as represented by the goblet and ciliated cells of the mucous membrane of the respiratory tract and the smooth muscle fibers of the bronchi. The chief hope for a specific treatment in the future lies in research which should extend along lines of study directed toward the development of a drug that will stimulate the body's defense reactions.

3335 West Twenty-Sixth Street.

Council on Physical Therapy

THE COUNCIL ON PHYSICAL THERAPY HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORTS. HOWARD A. CARTER, Secretary.

AMSCO OSCILLOMETER ACCEPTABLE

Manufacturer: American Medical Specialties Company, 131 East Twenty-Third Street, New York.

The Amsco Oscillometer, like other oscillometers, is devised primarily to provide a visual method for determining oscillometric indexes and blood pressure by measurement of the pulsations transmitted from a compressed artery to a manometer; the instrument may also be used as a simple anaeroid manometer to record blood pressures found by auscultation of arterial sounds. The firm recommends it for diagnosis of vasomotor disturbances, thrombo-angiitis obliterans, surgical shock, gangrenous conditions, Buerger's disease and the depth of anesthesia.

The instrument may be described as a double bladder arm cuff attached by two rubber tubes to a small, flat metal case having two chambers and dials, two levers and a rubber bulb. The lower dial records blood pressure and the upper one oscillations of the needle caused by blood vessel pulsations. The levers direct the pressure into one chamber or the other and regulate the air valve and the adjustments for finding various pressures. The device is built on the double anaeroid principle in a sealed chamber. It is made in Germany. The firm states, however, that in case of faulty performance it will be replaced or repaired by the dealer in this country.

The pamphlet of operating instructions furnished with the unit describes the changes in the excursion of the upper needle, which should indicate the various pressures and the oscillometric index. After pumping up the pressure in the inflation system and slowly releasing it as directed, a point is reached where the upper oscillometric needle starts to oscillate. At first the oscillations are weak, but at the moment of sudden increase in the excursion of the needle the maximal or systolic pressure is indicated and read from the lower dial. As the pressure is lowered, a sudden shortening of the oscillations should denote the minimum or diastolic pressure. This should be checked by the method of auscultation. Mean pressure is described as the point where the upper needle has its widest excursion after taking systolic pressure, just before the sudden shortening of the excursion in diastolic pressure. In taking the oscillometric readings, for which the instrument is primarily intended, the difference between the minimum and maximum excursion of the upper needle, which is the oscillometric index, is determined at any point.

For diagnosis of the condition of local arteries the firm suggests that it is unnecessary to use the double inflation cuff furnished with the unit; single cuffs in correct sizes are available for the purpose. For oscillometric readings on thigh or leg a special cuff, size 4 by 16 inches, is available; another one, 3 by 12 inches, is made for use on the arms, feet and ankles. The cuffs are applied similarly to the usual blood pressure cuffs and held in place by two slides and buckles.

The instrument was investigated by the Council. The use and accuracy of the Amsco Oscillometer in determining (1) systolic and diastolic arterial blood pressure by visual changes in the oscillations coinciding with these phases, (2) systolic and diastolic pressures in a manner similar to the use of the anaeroid sphygmomanometer with auscultation of the arterial sounds and (3) the oscillometric index of the lower extremities was studied. The values so obtained in 1 and 2 were compared with those from a mercury manometer by auscultation of the sounds, and the oscillometric index was compared to the readings determined by a control oscillometer.

The readings were obtained as closely together as possible to avoid natural fluctuations in these values and the same extremities were used in each case, the left arm for the determination of the arterial blood pressure and the left leg for the oscillometric index. The group studied consisted of ten patients presenting various manifestations of cardiac or peripheral vascular diseases and a control group of eight healthy young adults.

When determining the arterial pressure by auscultation, the systolic pressure was recorded at the first appearance of the sound and the diastolic at the point where the sounds showed their greatest change to a less intense noise. The oscillometric index was recorded as the maximal fluctuation over the arterial pressure at which it was observed. All the results are charted in the accompanying table.

From the results the following facts seem evident: The oscillometric indexes obtained from the Amsco Oscillometer bear a very close relationship to readings obtained with the control instrument as well as to the clinical condition presenting itself. The slight variations between the two sets of readings are unimportant and may be partially due to subjective sources of error. The visual systolic blood pressure readings agree

* Question mark indicates that end point is not clear.

very closely with those observed on a mercury manometer. The latter values are also about the same as those obtained when the Amsco Oscillometer was used as a simple anaeroid manometer with auscultation. However, the diastolic readings show a variation in many instances of from 10 to 15 mm. of mercury from values obtained by auscultatory methods and it was often nearly impossible to determine the visual change in oscillation that would denote the true diastolic pressure.

The instrument was found very compact, sturdy and relatively easy to use when determining oscillometric indexes. Visual arterial blood pressure determinations require somewhat more time than the auscultatory method and in general seem more likely to be liable to subjective sources of error, particularly the diastolic values.

In the opinion of the Council the Amsco Oscillometer is a sturdy, handy instrument the chief value of which lies in the determination of (1) oscillometric indexes, (2) the systolic and diastolic arterial blood pressures when used as a simple aneroid manometer with auscultation of the sounds and (3) the systolic pressure by the visual technic.

In the light of the foregoing report, the Council on Physical Therapy voted to accept the Amsco Oscillometer for the determination of (1) oscillometric indexes, (2) the systolic and diastolic arterial blood pressures when the instrument is used as a simple aneroid manometer with the auscultation of the sounds from the arteries and (3) the systolic pressure by the visual technic alone.

COOLEY COMPRESS ACCEPTABLE

Manufacturer: Hewitt Electric and Manufacturing Company, Somerville, Mass.

Distributor: R. K. Osborne, Rochester, N. Y.

The Cooley Compress is a heating pad intended to be used in applying hot wet compresses over limited areas of the body. A complete unit consists of electric heating pads of rubberized cloth (two 11 by 11 inches and one 7 by 7 inches), a control box to regulate current from any source of alternating or direct current to the wire coils in the pads, cloth compresses with thermometer sleeves (six 7 by 7 inches and twelve 11 by 11 inches) and special thermometers to be inserted between the pads (two of 12 inches and one of 6 inches).

Two pads may be attached to the control box at one time, and two switches are provided to regulate heat from "low" to

"high." Snaps are attached to the compresses and pads so that they may be fastened together, and eyelets are provided in the pads through which cloth tape may be passed to hold the pads around various parts of the body.

In tests of physical performance made under the auspices of the Council, it was found that each heating unit consumed 15 watts and that two units attached together raised the tem-

Cooley Compress.

perature between the wet compresses at the hottest point to 125 F. The control box operated satisfactorily.

The unit was submitted to a qualified physician, who reports that he tested it clinically in certain dermatologic and normal control cases. His observations were as follows:

Method: Three applications were made over the abdomen, three over the thigh and four over the arm. The flannel compresses were moistened in boric acid solution before application.

Thermometers were placed:

1. In the sleeve provided in the flannel compress.
2. Next to the skin under the compress with the bulb directly under the center of the involute coil.
3. Next to the skin, but about 2 inches from the center of the coil.

The temperature of the thermometer in the sleeve was kept as nearly as possible at 115 F.

Results: The temperature must be watched carefully, as it responds slowly to the rheostat adjustment.

The temperature of the thermometer next to the skin and under the coil ranged from 2 to 5 degrees F. below that of the thermometer in the compress.

The temperature of the thermometer next to the skin and 2 inches from the center of the coil ranged 15 degrees F. below that of the temperature in the compress; however, no "hot spots" were found in the periphery.

It was concluded that the pad might be used as a means of warming wet dressings. The heat can be regulated by means of the thermometer, since the bulb rests at the hottest point of the pad when inserted in the sleeve.

In view of the foregoing report, the Council on Physical Therapy voted to accept the Cooley Compress for inclusion in the Council's list of accepted devices.

BURDICK ULTRIPLEX UNIT SWD-70 ACCEPTABLE

Manufacturer: The Burdick Corporation, Milton, Wis.

The Burdick Ultriplex Short Wave and Ultra-Short Wave Diathermy Unit SWD-70 is recommended for medical and surgical use in the office or hospital. It is similar to the Council-accepted Triplex Short Wave Unit SWD-10 (*THE JOURNAL*, Dec. 12, 1936) except for the substitution of a shielded ultrashort wave 6 meter circuit in place of the 15 meter short wave circuit, and an 80 meter instead of a 70 meter long wave circuit, together with the necessary rearrangement of switches and wiring.

Two vacuum tubes and two rectifier tubes in a tuned-plate, tuned-grid, push-pull oscillator circuit generate high frequency energy at three different wavelengths. These include the 6 meter circuit for air-spaced electrodes, pads and cuffs, the 25 meter circuit for inductance cable and the 80 meter circuit for electrosurgery and conventional diathermy. There are five controls, one voltage control, one output control for the 6 meter circuit, one output control for the cable and surgery circuit, one dissection control for the surgery circuit and one filament voltage control. There are two meters, a voltmeter to register filament voltage and a milliammeter to indicate resonance.

Accessories include six air-spaced electrodes of varying shape and size, two 6 by 8 inch pad electrodes and one 12 foot inductance cable with spacers. The shipping weight of the cabinet is 340 pounds; the height 41 inches, the depth 19 inches and the width 24 inches. The arms are adjustable, with adjustable spacing guards for air-spaced electrodes.

Burdick Ultriplex Unit SWD-70.

Schematic diagram of circuit.

Regarding physical performance, the firm states that, when using three 200 watt lamps as a load, the maximum output at 6 meters is 500 watts, as measured by the photocell wattmeter method. Using two 200 watt lamps as a load, the maximum output on the 25 meter cable is said to be 475 watts, also measured by the photocell wattmeter method. There was no

calorimeter test. Under normal full load operation, using a lamp load of three 200 watt lamps, the input is recorded as 1,120 watts. After a two hour run at full load, the temperatures inside the transformer coils are stated as: plate transformer secondary, 76.5 C.; filament transformer primary, 57.5 C. The Council confirmed these measurements.

Average Temperatures (F.) of Six Observations

Technic	Deep Muscle		Oral	
	Initial	Final	Initial	Final
Cuff	99.3	107.9	98.2	98.6
Air-spaced electrode	99.9	107.6	98.5	99.1
Cable	99.6	106.6	98.8	99.6

The firm provided tests from a creditable laboratory concerning the capacity of the unit to produce heat deep in human tissues. In the cuff technic, double cuffs of $23\frac{1}{2}$ by $2\frac{1}{2}$ inches with $1\frac{1}{4}$ inch felt spacing were used. Current was applied up to the patient's skin tolerance to heat. In the air-spaced electrode technic, the air space averaged 2 inches and the centers of the electrodes were 10 inches apart. When the coil technic was used (25 meter circuit) the cable was given four turns and was wound round the thigh with six layers of bath towels for spacing, with each coil approximately 2 inches from its neighbor. Each application was given for twenty minutes.

The unit was operated clinically for the Council over a period of several months and found to render satisfactory service.

In view of the foregoing report, the Council on Physical Therapy voted to accept the Burdick Ultriplex Unit SWD-70 for inclusion in its list of accepted devices.

Council on Foods

ACCEPTED FOODS

THE FOLLOWING PRODUCTS HAVE BEEN ACCEPTED BY THE COUNCIL ON FOODS OF THE AMERICAN MEDICAL ASSOCIATION AND WILL BE LISTED IN THE BOOK OF ACCEPTED FOODS TO BE PUBLISHED.

FRANKLIN C. BING, Secretary.

- (1) NUTRADIET BRAND DELPHIA FIGS (WATER-PACKED)
- (2) NUTRADIET BRAND GRAPEFRUIT (JUICE-PACKED)
- (3) NUTRADIET BRAND PRUNES (WATER-PACKED)
- (4) NUTRADIET BRAND SPINACH (WATER-PACKED)

Manufacturer.—The Nutradiet Company, a subsidiary of S & W Fine Foods, Inc., San Francisco.

Description.—(1) Canned Kadota figs packed in water without added sugar, for use in carbohydrate-restricted diets.

(2) Canned Florida grapefruit segments packed in juice, without added sugar, for use in carbohydrate restricted diets.

(3) Canned stewed prunes packed in water without added sugar, for use in carbohydrate restricted diets.

(4) Canned spinach, packed in water without added salt, for use in salt restricted diets.

Manufacture.—(1) Tree-ripened California Kadota figs are graded, inspected, washed in hot water and filled into cans. Water is added. The cans are heated, automatically sealed and heat processed. Insecticide spray is used on the trees before the fruit appears.

(2) Tree-ripened grapefruit is scrubbed and washed under water sprays to remove any spray residue (the spray was applied when the fruit was very small), hand peeled and separated into segments, which are seeded and counted into cans. The cans are filled with grapefruit juice, sealed under vacuum, heat processed and cooled immediately.

(3) Sun-dried California prunes are washed, precooked in boiling water and steam, shaken over a screen to remove foreign matter, inspected and filled into cans. Water is added. The cans are preheated, sealed, heat processed and cooled.

(4) Fresh spinach is trimmed, cleaned, spray washed, blanched and filled into cans. Water is added and the containers are preheated, sealed and heat processed for the length of time and at the temperature prescribed and supervised by the State Department of Health of California.

Analyses (submitted by manufacturer).—

GERBER'S STRAINED LIVER SOUP WITH VEGETABLES, BARLEY, WHEAT GERM

Manufacturer.—Gerber Products Company, Fremont, Mich.

Description.—Canned strained soup mixture, containing beef liver, carrots, potatoes, lima beans, tomatoes, celery, onions, barley flour, wheat germ and salt.

Manufacture.—The vegetables are prepared and the product is packed essentially as described for Gerber's Strained Vegetable Soup (THE JOURNAL, July 22, 1933, p. 282). The beef liver is U. S. inspected and passed by the Department of Agriculture, and the product is packed under U. S. inspection.

Analysis (submitted by manufacturer).—Moisture 86.9%, total solids 13.1%, ash 0.8%, fat (ether extract) 0.4%, protein (N \times 6.25) 4.0%, crude fiber 0.3%, carbohydrates other than crude fiber (by difference) 7.7%, calcium (Ca) 0.0137%, phosphorus (P) 0.0674%, iron (Fe) 0.0028%.

Calories.—0.5 per gram; 14.2 per ounce.

Vitamins.—Vitamin A, 52.8 international units per gram, 1,500 per ounce; vitamin B₁ (thiamin), 0.22 international unit per gram, 6.3 per ounce; vitamin C (ascorbic acid), 0.02 mg. per gram, 0.7 per ounce (equivalent to 0.4 international unit per gram, 14 per ounce).

SIMS MALT-O-WHEAT

Manufacturer.—Sims, Division of Siems Bros., Inc., St. Paul.

Description.—Packaged, coarsely granular breakfast cereal; prepared from whole durum wheat with coarse bran and some fine flour removed. Toasted barley malt is added for flavor and the product is exposed to ultraviolet rays to destroy insect infestation.

Manufacture.—Durum wheat is cleaned by the usual milling methods, coarsely ground and bolted to remove fine flour and coarse bran; material of the desired granulation is mixed in definite proportions with toasted ground malted barley. The mixture is heated for a short period to destroy any insect infestation, passed under ultraviolet ray lamps for a similar purpose and automatically packed in cartons.

Analysis (submitted by manufacturer).—Moisture 11.7%, total solids 88.3%, ash 1.2%, fat (ether extract) 2.5%, protein (N \times 6.25) 17.1%, crude fiber 1.6%, carbohydrates other than crude fiber (by difference) 65.9%.

Calories.—3.6 per gram; 102 per ounce.

CHICAGO MEDICAL SOCIETY INSURANCE PLAN

The Chicago Medical Society has adopted a complete and unrestricted insurance plan for hospital and sanatorium care for its members. After two years of study, conducted by an employment insurance analyst, the society concluded that only cash indemnity plans should be considered.

The plan provides for private room service on a cash indemnity basis, allowing \$6 a day for either hospital or sanatorium confinement for a period of ninety-one days for each claim, plus an additional payment, up to \$30, for incidental expenses in connection therewith, such as operating room, anesthesia, laboratory, x-ray and ambulance charges. The number of claims in any one year for members under the age of 60 is not limited. Members of 60 years or older are provided ninety-one days at \$6 a day plus \$30 for incidental expenses in any one year. This is an unusual provision, since most plans limit the number of days of hospitalization in any one year to all members of the group. There are no restrictions as to diseases for which provision is made nor is there any physical examination required for the members of the original group. Later such an examination will be required. Any reputable hospital or sanatorium anywhere may be selected, and the insurance continues to the age of 70 for an annual premium of \$10. The plan is underwritten by an established life insurance company.

A supplemental plan, which will provide hospital and sanatorium benefits for the wives and children of the members of the Chicago Medical Society plan, is in preparation. Thus another of the leading medical organizations places its approval on the principle of insurance against the costs of illness, but at the same time affirms its conviction that voluntary action and cash indemnity are vital in plans that conform to the democratic concept.

DENTAL CARIES AND DOMESTIC WATER SUPPLIES

The occurrence of mottled dental enamel in persons who live in certain sections of the United States has been associated with the presence of fluorides in the supplies of drinking water. This observation, together with the knowledge that the ingestion of a few grams of sodium fluoride has proved fatal to human beings, would seem to show that the presence of appreciable amounts of fluorides in drinking water does not serve a useful purpose and is undesirable. As early as 1916, reports indicated that the teeth of children living in an area where mottled enamel was common compared favorably with those of children in other communities where endemic mottled enamel was unknown. More recently a report by Dean¹ covering a survey of a number of states points out that there was an inverse relationship between endemic dental fluorosis and dental caries, the severity of dental caries in general being lower in areas where mottled enamel occurs than in normal areas in the same states. Investigators in other countries have also noted that there is a lessened prevalence of dental caries among persons with mottled enamel or those who live in regions where endemic fluorosis exists.

Dean and his co-workers² have now carried out a new well planned investigation. It is known that factors such as age, sex and color may influence the amount of dental caries in a given group. The investigators attempted to take these factors into account. The study was limited to white children from 12 to 14 years of age in four cities in western Illinois. Although the communities were not greatly distant from one another, the water supplies of two of them differed in type and mineral composition from the domestic water of the others. There was notably a definite difference in the fluoride content. In two of the cities the water contained from 1.7 to 1.8 parts per million of fluorides, whereas the water of the other two communities was almost free of fluorides, containing only 0.2 part per million. The dental caries rate in the cities supplied with water almost free of fluorides was from two to three times greater than the rate observed in the other communities. An even greater difference was noted with respect to interproximal, or smooth surface, caries. When the approximal surfaces of the four superior incisors were chosen as a basis of measurement, it was found that there was sixteen times more interproximal caries in the groups studied in the cities where the water was extremely low in fluorides.

It seems reasonable to associate the lower rate of dental caries in two of the cities with the higher fluoride content of their communal water supplies; nevertheless the possibility is not excluded that the composition of the water in other respects may be the principal factor.

1. Dean, H. T.: Pub. Health Rep. 53:1443 (Aug. 19) 1938.

2. Dean, H. T.; Jay, Philip; Arnold, F. A., Jr.; McClure, F. J., and Elvove, Elias: Pub. Health Rep. 54:862 (May 26) 1939.

Consequently it seems highly desirable, as indicated by Dean and his collaborators, that studies of dental caries should be accompanied by complete chemical analyses of domestic waters including a search for comparatively rare elements. If this is done, any factor that is possibly being overlooked at present may be brought to light. In any case, considering the apparent similarity of the population groups studied by Dean and his co-workers and the results obtained, it would seem proper from an epidemiologic point of view to ascribe these differences to the composition of the water supplies. If this correlation proves correct, the possibility of partially controlling dental caries through the public water supply becomes of more than academic interest.

TWIN PREGNANCY

Single ovum twinning appears to be mainly a chance phenomenon. Double ovum twinning apparently is influenced by heredity, age and parity. In the first forty years of the obstetric department of Johns Hopkins Hospital, 521 cases of twinning occurred in the combined hospital and home delivery services, or about one set of twins in every eighty pregnancies, counting both viable pregnancies and the abortions. This ratio nearly agrees with that of the whole birth registration area of the United States. In a comprehensive study of this experience, Guttmacher¹ has published two papers and anticipates several others. Two methods are commonly employed to differentiate single from double ovum twins: first, the study of the twins themselves; second, the study of the placental relations. The diagnosis by the first method is best made when the twins are between 2 and 4 years of age. Numerous physical criteria must be satisfied. To diagnose a pair of twins derived from one egg, the two members of the pair must be of the same sex. Although their features, including ears and teeth, must be alike, this resemblance need not be absolute. Each member of the pair may be thought to represent but one half of a single zygote and therefore the twins need not resemble each other more closely than the two lateral halves of one individual. Their hair must be identical in color, texture, natural curl and distribution. They must have eyes of the same color and shade and have the same skin texture and color. They must have hands and feet of the same conformation and approximately the same size. Certain anthropometric values, cephalic index, forearm to upper arm length, and so on must show close agreement in the two members of the pair. They must have similar finger and sole prints.

In the second method of differentiation of single from double ovum twins, that of placental relations, it is assumed that if the embryos arise from two eggs they

have separate placentas or a fused single placenta with a four layer partition wall, the amnion and chorion of twin A in contact with the chorion and amnion of twin B. This can be determined by peeling apart the four separate layers. If the twins are derived from one egg, only two layers of amnion form the partition wall.

In the Johns Hopkins series of twins, and on the basis of placental relations, 25.7 per cent were derived from one egg. This figure is almost the same as Greulich's² 25.4 per cent, which was obtained by the other method of differentiation, the physical comparison of the twins themselves.

The most common age group for single ovum twinning in the Johns Hopkins series was between 20 and 25 years. Single ovum twinning occurred to the women of various parity with the same frequency that would be expected were it just a chance phenomenon; double ovum twinning, however, was infrequent in primiparas and secundiparas.

The antepartum diagnosis of twins frequently is difficult, having been missed in almost one third of a series of Johns Hopkins cases observed in a twelve year period. When both infants weighed less than 2,500 Gm., one half of the twin pregnancies remained undiagnosed, and when the larger twin weighed 2,500 Gm. or more, the correct antepartum diagnosis was made in about 70 per cent.

A difference in weight existed in the twins at birth of primiparas and multiparas. Among 127 primiparas, 36.2 per cent had twins of term weight; among 440 multiparas, 52.7 per cent had term fetuses. Considering any twin pregnancy a term pregnancy if either of the two infants weighs 2,500 Gm., 49 per cent of the series of twin pregnancies were delivered at term, 38.7 per cent were delivered prematurely and 12.3 per cent were aborted.

The twin pregnancies usually were more than two and a half weeks shorter than ordinary single pregnancies, the ratio having been 257.8 days versus 275.7 days, counting from the first day of the last menstrual period. The Negro women in this series of twin pregnancies had a shorter pregnancy by three and a half days than did the white women.

In smaller groups of twin pregnancies in which the hemoglobin was taken before iron therapy was given, the hemoglobin was below 70 in 40 per cent, while among the single pregnancies it was below 70 in only 11 per cent. Hypertensive toxemia was two and a half times as frequent in the twin pregnancies. Eclampsia occurred once in every thirty cases. The gravity of the association of toxemia with twin pregnancy was attested by the fact that 61 per cent of maternal twin deaths were associated with toxemias. Toxemic and functional vomiting were no more common, however, in twin than in single pregnancy.

Current Comment

RAPID DIAGNOSIS OF DIPHTHERIA

The contagious nature of diphtheria, as well as the prognostic significance of the time of administration of antitoxin, necessitates strenuous efforts at early diagnosis. A promising development in this direction was reported by Manzulla in 1938, who described a method for the diagnosis of diphtheria by which the diphtheria bacillus could be cultured in three hours and a macroscopic and microscopic diagnosis of the colonies made at the same time. He used a mixture prepared with 15 cc. of meat broth with peptone, 1.5 cc. of defibrinated ox blood and 1.5 cc. of a 2 per cent solution of potassium tellurite. The pharyngeal exudate was collected with a cotton swab and moistened with 2 cc. of the liquid mixture, placed in a test tube and left for three hours at a temperature of from 36 to 38 C. Small characteristic black colonies could be observed in the swab at the end of three hours, and these could be identified microscopically as diphtheria bacilli. A still more rapid method of diagnosis has been devised, consisting of moistening the pseudomembranes with a 2 per cent solution of sodium tellurite. When the throat is examined ten minutes later, the exudate, if diphtheric, has become black or gray. More recently the direct throat method has been investigated by Tomlin.¹ Tomlin applied the test to forty-six patients, forty-four of whom were admitted to the hospital for diphtheria or suspected diphtheria and two for scarlet fever. Of the forty-four cases, twenty-eight were proved to be diphtheria. Obvious darkening was obtained in twenty-seven of these, and in one darkening was suspected after ten minutes and was definite after thirty minutes. No case of diphtheria in this series would have been missed by placing reliance on the tellurite test. Fifteen of the forty-four cases were decided on bacteriologic and clinical grounds not to be diphtheria. Six of these failed to show darkening in the test. Nine of them did, however, and these represent therefore what might be called "false positives." A negative result, Tomlin concludes, is of value in that it supposes with great accuracy that the disease is not diphtheria. Such a high percentage of false positive results occur, however, that no positive diagnosis of diphtheria should be made on a positive result alone. The test, he believes, can in no way take the place of the clinical and bacteriologic methods of diagnosis already in use. Tombleson and Campbell² also have applied the direct method to a series of 200 unselected patients with pharyngeal exudate. After some experience with the test they found that some cases of diphtheria require more than one application of the tellurite solution before a positive result can be obtained. They obtained correspondence between this test and a bacteriologic diagnosis in 67.5 per cent and with a clinical

diagnosis in 77 per cent. Definite blackening of the membrane occurred in a high proportion (84.3 per cent) of the cases of diphtheria. However, similar blackening occurred in 46.8 per cent of faucial lesions due to other organisms. Further, no blackening at all occurred in a small number of cases of diphtheria even of a severe type. It appears, therefore, that with careful attention to technical details (including the undesirability of keeping a solution more than four weeks old) a negative observation affords presumptive evidence against diphtheria but a positive test does not establish the diagnosis. It is also agreed that the tellurite test cannot replace either clinical or cultural diagnosis. In spite of these shortcomings the test will probably prove extremely useful, especially in relation to epidemics or in cases in which the technical difficulties of isolating patients make it exceptionally important to procure an immediate presumptive diagnosis. Further investigation may indeed succeed in eliminating some of those who now react with a "false positive" test, which would, of course, enormously increase its usefulness.

U. S. DEPARTMENT OF JUSTICE SEEKS TO AVOID CIRCUIT COURT OF APPEALS IN APPEAL FROM JUSTICE PROCTOR'S DECISION DISMISSING INDICT- MENT OF A. M. A. AND OTHERS UNDER SHER- MAN ANTITRUST ACT

According to announcements appearing first in the press, the United States Department of Justice has filed in the United States Supreme Court a petition for a review of the decision of Justice Proctor of the United States District Court for the District of Columbia, dismissing the indictment of the American Medical Association and three other medical organizations and certain individual physicians under the Sherman Antitrust Act. The department seeks in this way to avoid a decision by the United States Circuit Court of Appeals for the District of Columbia, to which an appeal would ordinarily lie and to which the department had already appealed. The department seeks to justify this course on the ground that Justice Proctor's decision would ultimately reach the United States Supreme Court for review, no matter how the Circuit Court of Appeals might decide, and that the case would therefore be speeded and the public benefited by ignoring that court. This line of reasoning, if generally accepted, might relieve all United States circuit courts of appeal of a substantial part of their present work. Moreover, if the Supreme Court refuses to entertain jurisdiction, the actual settlement of the case may be retarded. A decision in the present stage of this case by either the Supreme Court of the United States or by the United States Circuit Court of Appeals must necessarily be limited to questions of law and will not determine in any degree the truth or falsity of the charges against the American Medical Association and others, formulated in the recently dismissed indictment.

ORGANIZATION SECTION

A NEW FEATURE IN INDIGENT MEDICAL CARE

ROLLEN W. WATERSON

Executive Secretary, Lake County Medical Society
WHITING, IND.

The history of medical relief for the indigent sick in Lake County, Ind., is a sordid tale of political intrigue, of investigations and indictments and public scandal . . . of all the abuses and inadequacies the profession has learned to expect when politics, now synonymous with government, gets control of the distribution of medical care. This year, however, certain local changes that are not important to this report have made possible the reorganization of the system, and the plan that has replaced it has reduced the cost of medical relief to approximately half last year's average and permits the indigent patient a free choice of physician.

Under the Lake County plan, a referral physician, a member of the Lake County Medical Society and preferably a general practitioner, is appointed to serve each month. He is responsible to the township trustee, who is overseer of the poor, for all medical opinions and decisions necessary to the proper administration of medical relief.

The indigent person in need of medical care applies for the attention of a physician at the office of the trustee. After the trustee has found that the applicant is entitled to medical care at public expense, the patient is given a purchase order on the physician of his choice for one call—an office call if the patient is ambulatory, a house call if he is not. (Except in the rare cases of actual emergency, the plan does not contemplate that any medical care shall be given without prior authorization: a written order from the trustee.) If the attending physician finds that the single office call is sufficient,

the case is closed. If, however, further medical care or hospitalization is necessary, the attending physician sends his written diagnosis and recommendations to the trustee, who in turn sends the patient to the referral physician. If the referral physician, after proper examination, agrees with the recommendations of the attending physician, the trustee issues another order, this one in the full amount for the services required according to an accepted reduced fee schedule. If, however, the referral physician disagrees with the attending physician, a second referral physician (who has been appointed for the month following) is called in, and the opinion of any two of the three physicians is accepted as final by the trustee.

Both for hospitalization and for medical care, the trustee may not be charged for more than the amount originally anticipated and written on the purchase order. If further care or extended hospitalization is considered necessary, a new order must be written by the trustee, again subject to the approval of the referral physician.

In practice the referral system, during its first four months of operation, has reduced both the cost of medical care and the cost of hospitalization to half the average for 1938 in the townships that include the industrial cities of Lake County: Gary, Hammond, Whiting, East Chicago and Indiana Harbor. Conditions peculiar to at least two of these cities, and not the fault of the referral system, still leave much to be desired; but, on the whole, the physicians, their indigent patients, the trustees and the taxpayers agree that the plan is the best yet conceived for the administration of medical relief.

A CONSULTATION SERVICE LIMITED TO PATIENTS OF LOW INCOME

REPORT AFTER SEVEN YEARS OF OPERATION

GEORGE BAEHR, M.D.

NEW YORK

In recent discussions concerning the medical care of people with small incomes, little attention has been devoted to the increasing need of general practitioners for the advice and guidance of experienced internists and specialists and for modern laboratory facilities. Because of the patient's inability to meet the additional cost of these specialized services, the general practitioner is confronted with the necessity of struggling on without the required assistance or with only a fraction of the special services which the problem demands. It is under these circumstances that medical care becomes inadequate for a large part of our employed population.

To meet this need, some hospitals have opened the doors of their outpatient clinics to a paying class of patients. These pay clinics are usually part of a public dispensary. The primary principle of sound medical practice, to encourage patients to remain in the hands of their family physicians, is in conflict with the function of the public dispensary which takes over the complete management of the patient. This conflict of purpose is in part responsible for the general unpopularity of the pay clinics and explains in part why they have largely failed to fulfil their purpose as the guide and

assistant of the general practitioner. Another reason is that the outpatient clinic of a hospital is manned largely by the younger and less experienced members of the medical staff so that the service rendered to the referring physician is usually not of consulting caliber.

In 1931 the medical staff of the Mount Sinai Hospital, New York, developed a plan designed to place all the experience and the facilities of a large general hospital at the disposal of the practitioners of the community and yet avoid the objectionable features of previous experiments of this nature. A Consultation Service for People of Moderate Means was established in November 1931 by the medical staff with the encouragement and cooperation of the trustees of the hospital. Details of the plan were published in *THE JOURNAL*.¹ The present report deals with the experience of the service over a period of more than seven years. Although the Consultation Service was established primarily as an experiment, the extent to which the physicians of the community have availed themselves of its facilities no longer leaves any doubt of the need for its continuation.

1. Baehr, George: A Consultation Service for Patients of Moderate Means, *J. A. M. A.* 98: 2159 (June 11) 1932; *ibid.* 102: 1305 (April 21) 1934.

During the seven years of operation, 3,527 physicians have referred 12,613 patients to the Consultation Service for diagnostic investigation. The continued growth of the service has been limited only by the fact that the available staff and facilities could no longer be expanded without loss of efficiency. For more than three years the service has functioned continuously at its maximum capacity. Throughout these years there has always been a waiting list of referred patients and many have been turned away.

The cordial relationship between the Consultation Service and the local medical profession has been due to strict adherence to the principles on which it was primarily established. No patients are accepted unless referred by their physician. The work is limited to diagnosis. The clinical investigation is carried out by internists, surgeons and specialists who are the members of the visiting staff of the hospital proper. At its conclusion, the patient is returned to the referring physician with as complete a diagnostic opinion as possible, together with detailed advice concerning appropriate therapy. Although no therapy is practiced, the physician who refers a patient is free to avail himself of the advice and guidance of the staff in carrying out the therapeutic procedures recommended.

Number of Patients Admitted Each Year

1932.....	996 (Nov. 1931 to Dec. 30, 1932)
1933.....	956
1934.....	1,242
1935.....	1,747
1936.....	2,226
1937.....	2,658
1938.....	2,788
Total.....	12,613

As the aim of the service is to cooperate with practitioners in the medical care of people of limited means, the economic level of eligibility is a maximum income of \$2,400 a year for unmarried persons and \$4,000 for total family income. For families of more than five members, an extra allowance of \$400 is added for each additional dependent. Physicians are requested to refer only patients who fall within this economic group and the patients must give satisfactory information concerning salaries and total family income before they are accepted.

A flat fee of \$35 is charged all patients regardless of the illness or the number of consultations and laboratory examinations that may be required. The advantage of the flat fee is that the patient knows the total cost in advance irrespective of the nature of the condition that may be found and the number or complexity of the diagnostic procedures that may prove necessary; the physicians of the consultation service do not find themselves restricted in the thoroughness and completeness of their diagnostic investigation by the patient's financial limitations.

To avoid interference with the practice of individual consultants, the fee was set at about double the average amount charged patients of this class by a specialist for an individual consultation or major laboratory examination. This has served automatically to exclude most patients with simple conditions which require only the services of a single specialist.

First appointments for new patients are made either for Monday, Wednesday or Friday afternoons, when they are interviewed by the associate director and

referred to an internist. On the intervening days of the week they return for special diagnostic procedures, for the specialist consultations and for confirmatory reexaminations of various kinds. The patients average five visits, or about seven to ten days for completion of the study. Unusually difficult or complicated cases require a longer period. Two or three additional days are necessary before all reports are received and

Geographic Distribution of Physicians Who Referred Patients

recorded and the case is summarized by the associate director of the service. If there is any doubt about the accuracy of the diagnosis or the completeness of the investigation, the patient is summoned for a reexamination by the director or associate director before the final report is made to the referring physician.

The referring physician actually receives a complete transcript of the entire record, which includes in its final form a correlation and interpretation of all observations by the director or associate director of the service. The director reviews and initials a first draft of every report before it is transcribed into its final form.

All members of the visiting staff of the hospital are available for service; full attending physicians and specialists are called whenever justified by the unusual nature of the case, and they respond as promptly as the junior members of the staff. Because the daily work of the service makes large demands on their time, internists, gynecologists and otolaryngologists are employed during periods when they are not on ward duty in the hospital.

Number of Patients Referred by Individual Physicians

1,473 physicians referred.....	1 patient
736 physicians referred.....	2 patients
787 physicians referred.....	From 3 to 5 patients
346 physicians referred.....	From 6 to 10 patients
147 physicians referred.....	From 11 to 25 patients
28 physicians referred.....	From 25 to 50 patients
5 physicians referred.....	From 50 to 100 patients
3 physicians referred.....	More than 100

All other specialists, who are required irregularly, are called when on ward duty, for they are then in the hospital and are more promptly available for consultations.

In about 15 per cent of the cases no significant organic disease can be discovered and the illness must be ascribed to a psychoneurosis. The diagnostic investigation of such patients usually requires an unusually large number of costly clinical and laboratory investigations because of the variety of somatic complaints and the need for convincingly eliminating the possibility of obscure organic disease. At the conclusion of the investigation these patients are always studied by a psychia-

trist. Because of his greater experience and skill he is usually able to elicit important information covering significant environmental and social factors and aberrations in personality or behavior of which the family physicians are unaware. Details of the conclusions and recommendations of the psychiatrist are recorded in a supplementary confidential report to the referring physicians.

Under the original arrangement with the hospital, which has proved to be mutually agreeable, the gross income is shared equally between the participating physicians and the hospital. Half the gross income per month is therefore available for payment of the medical staff. Consultants are credited with half a work unit for one consultation and with a full work unit for two or more consultations during the same afternoon. The internists receive credit for one work unit for seeing three new patients in a period of two hours. The director is credited with four work units a week and the associate director, who is on duty half of every day, is credited with six work units a week.

At the end of each month the value of the unit is determined by dividing the total number of earned units into half the gross income. The funds are then distributed monthly to those who rendered any medical

The surplus remaining from that half of the gross income used to reimburse the hospital for all operating expenditures other than payments to clinicians is now being applied toward repayment of the loan of about \$15,000 for the original equipment and furnishings. It is planned to use part of any future operating surplus to build up a small reserve fund for equipment replacements and the remainder will be applied to the benefit of the participating clinicians.

The need for a consultation service for people of moderate means is best demonstrated by the number and proportion of practicing physicians in the community who have used it for the investigation of patients with clinically obscure conditions which in their opinion required multiple consultations and laboratory examinations in order to establish a diagnosis.

The 3,527 physicians include 1,012 who practice in Manhattan, 1,542 who practice in the other boroughs of the city and 862 who live within a radius of 50 miles from the center of the city but outside of greater New York, a total of 3,416 metropolitan physicians. Patients were referred by 111 physicians living outside a radius of more than 50 miles from the center of New York city. If we can assume that there are 13,000 actively practicing physicians in the metropolitan area, the 3,416

Financial Statement

Accumulated deficit.....	11,511.79	14,368.59	13,963.86	9,650.47	4,736.98	1,290.51

service during the previous month. The value of the unit fluctuates monthly between \$13 and \$15. Specialist consultants therefore receive from \$6.50 to \$7.50 for each consultation. An internist who works three afternoons a week receives from \$150 to \$180 a month. Specialists doing the largest volume of work may earn up to \$400 in a month. In order to distribute the income equitably, the service is rotated among most of the members of the visiting staff during the course of the year.

Half the gross income remaining after payment of the medical staff is used by the hospital for the payment of the administrative, technical and secretarial staff of the Consultation Service, for light, heat and building maintenance, for cleaning and laundry services and for the actual cost of all services rendered by the various central laboratory departments. In arriving at estimates of the cost of services of this nature shared with other departments of the hospital, an equitable proportion of administrative and other general expenses is included. Nothing is charged for rent or for interest on a capital investment of about \$15,000 which is to be repaid out of future earnings.

As the service is designed for patients of very moderate means, the hospital has agreed to derive no profit from the operation of the Consultation Service either directly or indirectly. During the first three years there was an accumulated net operating deficit of \$14,368.59. This deficit in annual payments to the hospital for services rendered at cost was carried as a loan. Since 1935 an annual net operating surplus has permitted us gradually to liquidate this debt in full (1939).

metropolitan physicians who have patronized the consultation service constitute more than 26 per cent of the physicians in the area.

The increasing interest of practitioners is suggested by the fact that 632 new physicians referred patients for the first time during 1938, the seventh year of operation. Among the 1,473 physicians who have referred only one patient are most of the 632 who used the service for the first time in 1938. Two or more patients were referred by 2,052 physicians, of whom 529 referred more than five.

In the last few years a serious deterrent has been the fact that physicians have been obliged to wait two weeks or longer for an appointment unless the patient's condition was regarded as extremely urgent. Limitation of the maximum number of new appointments to sixty a week was considered necessary in order to maintain a proper standard of careful, thorough work.

Operation of the Consultation Service to the satisfaction of the physicians of the community and of the members of the hospital's medical staff is due in large part to the enthusiasm of those who have administered the service and, above all else, to the efficiency and tact of the nurses, secretaries and volunteer assistants who act as intermediaries between the patients, the referring physicians and the clinicians who participate in the investigations. If the volume of work were permitted to outgrow the physical facilities and the available medical staff, the service would inevitably become routinized and soon lose its personal character; detailed supervision would be more difficult.

The steady growth of the service can be visualized from the financial statement of the years 1932 to 1938. The total annual income of the clinicians is slightly less than half the gross income, owing to the fact that half of each fee to which they are entitled was remitted to physician patients and to the dependents of physicians. Both the gross income and the total annual income to clinicians increased more than three fold between 1932 and 1938.

This ambulatory consulting service represents a substantial expansion of the hospital's activities. The number of obscure diagnostic problems which are studied annually now equals or exceeds the total number of similar problems investigated by the entire medical division of 150 beds during the course of a year. The medical problems presented by the patients of the consultation service are as important as those encountered in the hospital; in fact, they are apt to be more important to the patients because they represent the beginnings of disease, when patients are still in the operable or otherwise curable stage of their illness.

In the light of this experience of seven years, the Consultation Service may be regarded as a successful experiment in placing the professional and physical facilities of a large, well equipped general hospital at the disposal of the practicing physician of the community for the benefit of patients of low income. It has given these people a type of complete service which they could not otherwise have secured and it has enabled them to conserve their slender resources for the subsequent treatment of their disease. It has undoubtedly enabled a large number of physicians to retain private patients whom they might have lost to the public wards and clinics. Through the Consultation Service the hospital is making and maintaining new contacts with hundreds of physicians and is steadily expanding its influence on the practice of medicine outside its walls.

110 East Eightieth Street.

LONGER LIFE FOR AMERICANS

"The health of the American people is getting better all the time, and their average length of life is increasing accordingly," is the conclusion of the Statistical Bulletin of the Metropolitan Life Insurance Company (20: 1 [Aug.] 1939):

"Since the turn of the century the average length of life of the white boy baby has increased by twelve and one-half years; in 1937 his expectation of life at birth was 60.75 years, whereas in 1901 it was only 48.23 years. For the white girl baby the gain in average length of life over the same period has been even greater and amounts to fourteen years, the improvement being from an expectation of life at birth of 51.08 years in 1901 to one of 65.08 years in 1937. Our women do better than our men by four years and four months.

"These gains have been accomplished despite the World War, an influenza pandemic which destroyed even more human lives than did the war, and the greatest economic upheaval of generations, with its health-menacing potentialities. . . .

"In 1901 less than nine out of every ten white male babies born alive survived to reach their first birthday. However, by 1937 health conditions had improved to such an extent that at least nine out of every ten newly born will attain age 24. Among white girl babies, too, less than nine out of every ten born in 1901 survived their first year of life; but in 1937 the conditions were such that nine out of every ten babies will reach age 32. According to the situation prevailing in 1901, almost half of the white male babies would have died before attaining age 57, while the half-way mark on the basis of health conditions in 1937 was at 67 years. For white females the corresponding ages were 61 years in 1901 and 72 years in 1937. With half our women-folk surviving beyond the 70 year mark, we can well understand why our population is rapidly growing older."

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

ILLINOIS

Strike for Safe Water at State Hospital.—Several hundred workmen, who went on strike at the state hospital for the insane near Manteno because of the epidemic of typhoid there, returned to work September 6 after they were promised a satisfactory water supply, according to the *Chicago Tribune*. Laborers and skilled workmen, who have been constructing new buildings at the hospital, quit work several days prior to this after a futile demand that contractors be responsible for all expenses if they contracted typhoid while at work, it was stated. The men agreed to resume work when the contractors arranged to haul drinking water from the village of Manteno. The *Tribune* stated that polluted water from artesian wells at the hospital is believed to be responsible for the epidemic which has taken thirteen lives and made hundreds ill.

Chicago

Joint Meeting on Tuberculosis.—Dr. Erik Hedvall, director of the University Tuberculosis Clinic and assistant professor of tuberculous diseases, University of Lund, Sweden, will address a joint meeting of the Institute of Medicine of Chicago and the Chicago Tuberculosis Society at the Palmer House September 22. His subject will be "How Does Pulmonary Tuberculosis Begin in Adults?"

IOWA

Upper Des Moines Society Meeting.—The summer meeting of the Upper Des Moines Medical Society was held at The Inn on Lake Okoboji August 17. Included among the speakers were Drs. Claude F. Dixon, Rochester, Minn., on "Malignancy in the Large Bowel"; Rollin Russell Best, Omaha, "Practical Management of Biliary Tract Diseases," and Samuel E. Sweitzer, Minneapolis, "The More Common Skin Diseases, Their Diagnosis and Treatment." Dr. Felix A. Hennessy, Calmar, president of the state medical society, spoke on medical economics.

Personal.—Dr. Max L. Durfee of the staff of the health service of the University of Michigan, Ann Arbor, has been appointed director of the health service at Iowa State Teachers College, Cedar Falls, it is reported.—Dr. Forrest J. Austin, formerly of Houghton, Mich., has been appointed director of a district health unit for Webster, Calhoun and Boone counties.—Dr. Ellis K. Vaubel, Indianapolis, has been appointed assistant director of the division of preventable diseases of the state department of health, succeeding Dr. Paul Stephen, who resigned to enter private practice at Manchester.

KENTUCKY

Changes in Health Officers.—Dr. Neale M. Atkins, Greenville, health officer of Muhlenberg County, has been transferred to Graves County to take charge of a new unit with headquarters at Mayfield.—Dr. Don V. Hatton, Leitchfield, has resigned as health officer of Grayson County to take a similar position in Virginia.—Dr. James O. Nall, Clay, has been appointed health officer of Lawrence County, with headquarters at Louisa.

Society News.—Drs. Joseph Garland Sherrill and Archibald M. McKeithen will address the Jefferson County Medical Society, Louisville, September 18 on "Surgery of the Gallbladder and Biliary Passages" and "Preoperative and Postoperative Care in Diseases of the Gallbladder and Common Duct," respectively.—Dr. Chauncey W. Dowden will address the Louisville Medico-Chirurgical Society September 22 on "Differentiation of Myocardial Disease and Gallbladder Disease."

LOUISIANA

Ban on Ethyl Glycerin.—The state board of health issued an order August 25 forbidding the use of ethyl glycerin in flavoring extracts or drugs marketed in Louisiana until the board has had an opportunity to test and approve it. The new chemical compound takes the place of alcohol in flavoring extracts and has been recommended for use in a similar manner for drugs. It is not subject to tax and is therefore cheaper than alcohol, the health department commented.

MARYLAND

Pneumonia Campaign.—The state department of health will begin a fall campaign against pneumonia with an institute for county health officers, public health nurses and laboratory workers in Baltimore September 22. The morning session will be devoted to discussions of pneumonia control and the afternoon to instruction in laboratory procedure. Instruction in the most recent methods of treatment will be given by Drs. Perrin H. Long and Horace L. Hodes. Funds were appropriated by the last session of the legislature for pneumonia control and treatment. The health department will now be able to provide the necessary laboratory aid for physicians and to furnish the drugs for residents of the counties unable to buy them.

MASSACHUSETTS

Fundamentals of Health Education.—A survey course in fundamentals of health education will begin at Boston University School of Education September 25 to continue weekly until January 22. The speakers will include:

Dr. Harold C. Stuart, Boston, Maternal and Infant Care.
Elmer V. McCollum, D.Sc., Baltimore, Nutrition.
Dr. Karl A. Menninger, Topeka, Kan., Family Relationships.
Dr. George H. Ramsey, White Plains, N. Y., Communicable Diseases.
Dr. Shailer U. Lawton, New York City, Mental Hygiene.
Dr. Edmund Jacobson, Chicago, Relaxation.
Dr. Esmond R. Long, Philadelphia, Tuberculosis.
Frederick R. Rogers, Ph.D., Boston, The Measurement of Physical Fitness.
Austin H. MacCormick, commissioner of correction, New York, Governmental Relationships.
Dr. Henry D. Chadwick, Boston, State and Local Public Health Department Educational Functions.
Dr. Walter S. Cornell, Philadelphia, Local School Health Department Organization and Services.
Alexander J. Stoddard, Philadelphia, Functions of School Administrators and Boards of Education in Conserving Community and National Health.
Irving Fisher, LL.D., New Haven, Economics of Health Education.
Frank P. Graves, LL.D., New York, A Tentative Prognosis: The Future of Health Education.

MICHIGAN

Poliomyelitis Declines in Detroit.—Schools will open in Detroit September 18. The recent outbreak of poliomyelitis, newspapers reported, caused the Detroit Board of Education to delay the opening of schools on the advice of the city board of health, although suburban schools and Wayne University were to have opened on schedule. With three new cases of poliomyelitis and one death September 5, the number of active cases in Detroit was given as seventy-seven with fifteen deaths. There were 260 cases reported in August.

MINNESOTA

Fraternal Order Must Give Members Choice of Physician.—Attorney General J. A. A. Burnquist recently ruled that a fraternal order may not legally furnish medical services if it designates and controls the physician in attendance on the patient. The ruling was made at the request of the state board of medical examiners, which reported that one order is furnishing service to 1,200 members and their families through such an arrangement. The fraternal order is jeopardizing its corporate charter in lending itself to this practice, which constitutes practice of medicine by a corporation, the attorney general said. "For a doctor to aid a corporation or a layman to practice medicine unlawfully is a violation of the statute," Burnquist said. "A licensed physician should not aid or abet any one to practice medicine unlawfully, and it follows that if he does so he is guilty of immoral, dishonorable and unprofessional conduct within the meaning of the law." The attorney general pointed out that the right of a fraternal order to furnish sick benefits is not otherwise impaired if it complies with the other laws of the state; it is designation and control of the physician in attendance on the patient that is objectionable.

MISSISSIPPI

New Program on Venereal Diseases.—Dr. Paul T. Erickson, U. S. Public Health Service, arrived in Jackson recently to launch a year's program in the control of venereal diseases in cooperation with the state department of health. He will maintain headquarters in Jackson and work throughout the state. Dr. Erickson recently completed a course on venereal diseases at Johns Hopkins University.

Society News.—Dr. Luther L. McDougal Jr., Paris, Texas, addressed the Northeast Mississippi Thirteenth Counties Medical Society in Aberdeen September 12 on "The Feeding of the Normal Child."—Dr. Leon H. Brevard, Deeson,

addressed the Coahoma County Medical Society at a meeting with the Clarksdale Hospital medical staff August 9 on amebic dysentery.—At a meeting of the Issaquena-Sharkey-Warren Counties Medical Society August 8 Drs. Alfred J. Messina and Guy P. Sanderson, Vicksburg, spoke on "Some Uses of Sulfapyridine" and "Endometriosis" respectively.—Dr. John H. Musser, New Orleans, discussed pneumonia before a meeting of the Coast Counties Medical Society in Biloxi August 2.

Changes in Health Officers.—Dr. William D. Smith, Senatobia, has been appointed health officer of Tate County, succeeding Dr. John Sidney Eason, Coldwater.—Dr. John E. Tate, Ripley, has been appointed health officer of Tippah County for a two year term.—Dr. Ransom J. Jones, Poplarville, formerly director of the Pearl River County health department, has been named to a similar position in the southeastern district, it is reported. This district, composed of George, Greene, Perry and Stone counties, was organized in March; Dr. John W. Dugger, Jackson, has been acting head.—Dr. Richard B. Austin, Forest, has been named part time health officer in Scott County, filling the unexpired term of Dr. William E. Anderson, who has moved to Dyersburg.

NEW JERSEY

Infantile Paralysis Delays Opening of Schools.—Opening of public and parochial schools in Camden and several suburbs has been delayed until September 18 because of infantile paralysis. Newspapers report that sixty cases have occurred in this area since July 1 with eight deaths.

Laboratory for Study of Viruses.—A new laboratory for the study of filtrable viruses has been established at New Brunswick by the Squibb Biological Laboratories and Raymond C. Parker, Ph.D., a member of the staff of the Rockefeller Institute for Medical Research, has been appointed director, it was announced August 29. A special building has been equipped for the research. Dr. Parker is a native of Nova Scotia and took his doctorate at Yale University, New Haven, Conn., in 1927.

NEW YORK

Epidemic of Sore Throat.—Eighty cases of septic sore throat recently occurred in a boys' camp at Deer Park, Orange County, the state health department reports. Investigation was being continued to determine whether an infected food handler had been the source of infection.

Society News.—Dr. Paul Reznikoff, New York, will address the Medical Society of Westchester County, White Plains, September 19 on "Disorders of the Blood in General Practice."—Dr. Frederick W. Bancroft, New York, addressed the Dutchess County Medical Society September 13 on "Technic of Appendectomy."

Typhoid Carriers Supervised.—The state department of health reported July 31 that 412 typhoid carriers were under supervision at the end of 1938. Forty-five new carriers were added to the list and thirty-one removed. Of the new carriers, twenty-seven were discovered as a result of an investigation of sporadic cases of typhoid, ten through release cultures and the remainder through other circumstances. Of those removed sixteen died, several were released after tests had shown they were no longer carriers and others moved to other health jurisdictions. Two typhoid outbreaks during the year were traced to carriers, *Health News* reports. One was caused by a carrier who supplied raw milk and the other by a carrier who prepared picnic food.

New York City

Hospital Commissioner Proposes Ten New Hospitals.—Dr. Sigismund S. Goldwater, commissioner of hospitals, proposed ten new city hospitals to be erected in the next six years in a budget presented to the city planning commission August 14. The hospitals, which would cost about \$56,000,000, would be located as follows:

Brownsville, Brooklyn, general hospital and dispensary, 600 beds.
Harlem-Bronx district, tuberculosis, 500 beds.
Harlem district, Manhattan, general hospital and dispensary, 500 beds.
Queens, general hospital and dispensary, 500 beds.
Bay Ridge, Brooklyn, general hospital and dispensary, 300 beds.
Bronx, general hospital and dispensary, 500 beds.
Coney Island, Brooklyn, general hospital and dispensary, 300 beds.
Welfare Island, Manhattan, cancer hospital, 400 beds.
Manhattan, West Side, new city hospital to replace present City Hospital on Welfare Island.
Brooklyn, near Kings County Hospital, venereal disease hospital, 400 beds.

Examination for Psychiatrist.—The National Committee for Mental Hygiene announces that an examination will be held in the near future for the position of school psychiatrist

for the public schools of New York. Applicants must be between 30 and 45 years old, graduates from approved medical schools and must hold licenses to practice in New York. They must have had twelve semester hours in approved courses in psychiatry and psychology and six semester hours in education. They must also have had five years of practice in psychiatry, including 800 hours of experience in approved institutions for treatment of mental disease and mental defects and 1,200 hours in clinics for personality and behavior disorders of children. Information may be obtained from Joseph K. Van Denburg, Board of Examiners, 500 Park Avenue, New York.

FCC Denies Automobile Paging Service.—The Federal Communications Commission recently denied an application by the Doctors' Telephone Service for a permit to construct a special emergency radio station to page physicians in their automobiles. The commission maintained that the need for such service was not established in the application. It was estimated that about seventy-five occasions would arise each day when the radio paging service would be desirable, but the commission said that the fact that a subscriber was wanted on the telephone did not prove that an emergency existed. The report noted that no representatives of the medical profession appeared in support of the application. Frequencies of the type requested for this service have a limited range of effectiveness, with interference from automobile ignition and other electrical sources at distances beyond 10 miles from the transmitter. For this reason such a station would not render complete service in the New York area.

NORTH CAROLINA

Institute for Hospital Administrators.—The first southern institute for hospital administrators was held at Duke University, Durham, the first two weeks in August with seventy-two hospital officials present from sixteen states. Lectures were presented at morning sessions and the administrators visited hospitals in various towns each afternoon for demonstrations. The sponsoring agencies included the American College of Hospital Administrators, the Southeastern Hospital Conference, the Carolinas-Virginia Hospital Conference, the University of North Carolina and Duke University.

Personal.—The Guilford County Medical Society honored Dr. Merle D. Bonner, superintendent of the Guilford County Tuberculosis Sanatorium, Jamestown, with a silver plaque for outstanding medical work during the year, presented at a dinner meeting August 3. Dr. William de B. MacNider, dean, University of North Carolina School of Medicine, Chapel Hill, was the principal speaker.—Dr. Fletcher R. Adams, Monroe, health officer of Union County, has been appointed health officer of Catawba County, to succeed Dr. Clarence H. White, formerly of Newton and now of Philadelphia.—Dr. Johanna Christine Thelen, Madison, Wis., has been appointed college physician at Greensboro College for Women.

OHIO

Lectures for Practitioners.—A course of free lectures on recent advances in medicine and surgery will be presented at the Cleveland City Hospital on Mondays, Wednesdays and Fridays during October. Western Reserve University School of Medicine is offering the course through the staff of the hospital. Lectures will last an hour and will be followed by a question period of an hour.

Dr. Sabin Goes to Cincinnati.—Dr. Albert B. Sabin of the Rockefeller Institute for Medical Research, New York, has been appointed associate professor of pediatrics at the University of Cincinnati College of Medicine, Cincinnati. He will also hold a research fellowship with the Children's Hospital Research Foundation. Dr. Sabin graduated from New York University College of Medicine in 1931.

Annual Northwestern Ohio Meeting.—The ninety-fifth annual meeting of the Northwestern Ohio Medical Association will be held at Van Wert October 3. The scientific program includes:

Dr. Carl E. Badgley, Ann Arbor, Mich., Fracture of the Femur.
James T. Bradbury, Sc.D., Ann Arbor, Therapeutic Endocrinology;
Laboratory Aspects of the Sex Hormone Preparations.
Dr. Harry A. Towsley, Ann Arbor, Contagious Diseases.
Dr. Albert C. Furstenberg, Ann Arbor, Acute Infections of the Mouth, Throat and Neck.
Dr. Walter M. Simpson, Dayton, Undulant Fever.
Dr. Frederick A. Collier, Ann Arbor, Treatment and Closure of Wounds.

Dr. Edward J. McCormick, Toledo, councilor of the fourth district of the Ohio State Medical Association, will deliver an address at a luncheon on "The Socialization Problem Confronting Present Day Medicine." A golf tournament will be held Monday afternoon October 2 at the Willow Bend Country Club.

PENNSYLVANIA

State Medical Meeting at Pittsburgh.—The eighty-ninth annual meeting of the Medical Society of the State of Pennsylvania will be held in Pittsburgh October 2-5. In addition to an opening general meeting Tuesday evening October 3 there will be general scientific sessions Wednesday and Thursday mornings. Guest speakers announced for general and section meetings are:

Dr. Walter L. Winkenwerder, Baltimore, Relationship of Urticaria and Angioneurotic Edema.
Dr. Charles H. Peckham Jr., Baltimore, The Toxemias of Pregnancy.
Dr. Armand J. Quick, Milwaukee, Clinical Significance of Prothrombin as a Factor in Hemorrhage.
Dr. Walter G. Maddock, Ann Arbor, Mich., Research and Its Application to the Water and Salt Balance Problem (in a symposium on salt and water balance and acid-base equilibrium).
Dr. Stuart W. Harrington, Rochester, Minn., Diagnosis and Surgical Treatment of Carcinoma of the Breast with Five, Ten, Fifteen and Twenty Year Results and Factors Which Influence Prognosis.
Dr. Algernon B. Reese, New York, Determination of the Cause and Surgical Treatment of Unilateral Exophthalmos.
Dr. Ferris Smith, Grand Rapids, Mich., Correlation of Chronic Infection of the Upper and Lower Respiratory Tracts.
Dr. Bronson Crothers, Boston, Appraisal of Children After Birth Injury.
Dr. John A. Toomey, Cleveland, Management of Scarlet Fever and Its Complications.
Dr. George C. Andrews, New York, Nutritional Disturbance in Relation to Skin Diseases.
Dr. Reed M. Nesbit, Ann Arbor, The Neurogenic Bladder.
Dr. Joseph L. Baer, Chicago, Treatment of Prolapse of the Uterus.

The program of the general sessions has been arranged around specific subjects, with addresses followed by round table discussions. Subjects for Wednesday morning are syphilis, allergy and maternal welfare; for Thursday morning they are appendicitis, chemotherapy in pneumonia and mental health. The annual golf tournament will be played Monday October 2 at the Edgewood Country Club.

Philadelphia

Society News.—The First Councilor District, which is confined to Philadelphia County, will hold its annual meeting Wednesday afternoon September 20 at the headquarters of the Philadelphia County Medical Society. Drs. David W. Thomas, Lock Haven, president of the Medical Society of the State of Pennsylvania, and Rufus S. Reeves, president of the county society, will make addresses and speakers on the scientific program will be: Drs. Harry L. Bockus, on "Medical Treatment of Peptic Ulcer" and Jacob H. Vastine, "The X-Ray in Peptic Ulcer." Charles E. Kenworthy, an attorney, will speak on "What Is Malpractice?" In the evening the county society will hold its inaugural meeting of the season. Dr. Thomas will speak on "The Value of Medical Organization." Dr. Reeves will be installed as president to succeed Dr. Francis F. Borzell and Dr. Frank H. Lahey, Boston, will address the society on "Surgical Treatment of Peptic Ulcer." In addition to these meetings the woman's auxiliary of the first district will meet in the afternoon with the following speakers, among others: Drs. Stanley P. Reimann, on "Advance Treatment and Control of Cancer"; Elmer Paul Reiff, "Importance of Immunization"; Burgess Lee Gordon, "New Methods of Control of Pneumonia and Tuberculosis" and Leonard F. Bender, "Child Welfare."

TENNESSEE

Personal.—Dr. William C. Sanford, Cleveland, who has been director of the Bradley County health department for nine years, has been appointed health commissioner of Chattanooga. He succeeds Dr. John W. L. Cooper, who resigned to devote full time to private practice.—Dr. Enoch W. Tip-ton, Kingsport, has been elected mayor of the town.

Changes at State University.—Oren W. Hyman, Ph.D., administrative officer of the University of Tennessee College of Medicine, Memphis, has been appointed dean of administration, it was reported August 1. Dr. Conley H. Sanford, associate professor of medicine, has been made professor and head of the department of medicine to succeed Dr. James B. McElroy, who resigned because of ill health. Dr. McElroy will continue as professor, however, according to the report. Among other changes, Dr. Robert H. Miller, associate professor of anatomy, has been made assistant dean; Dr. Lathan A. Crandall Jr., Chicago, professor of physiology, and Dr. Lucius C. Sanders, Memphis, assistant professor of medicine.

State Aid for the Tuberculous.—With funds appropriated by the 1939 legislature, the state department of health has begun a tuberculosis hospitalization service for indigent patients for whom collapse therapy is suitable. The new service is a statewide application of the short hospitalization and outpatient follow-up plan that has been used in many cities, the health department reports. Tennessee has no state-owned tuberculosis

hospitals, but a number of approved general hospitals distributed through the state are available. Hospitalization costs are met by funds supplied jointly by local communities and the state and treatment will be given by local physicians. The function of the new service is to correlate services and agencies already functioning and to furnish consultation when indicated. It is believed that the program will aid in health education, promote the use of established hospitals, provide some care that has hitherto not been available and provide data for further approach to the tuberculosis problem. Dr. Wilder W. Hubbard, Nashville, is in charge of the tuberculosis service, which is a unit of the division of preventable diseases in the state department of health. To assist in formulating policies an advisory council has been appointed with the following members: Drs. James L. Hamilton, Chattanooga; William S. Rude, Ridgely; Charles M. Oberschmidt, Memphis; William J. Cameron, Sweetwater, and Dr. David Mendenhall, Bristol.

TEXAS

Millions Bequeathed to Advance Mental Hygiene.—University of Texas has received a bequest valued at \$1,000,000 from the estate of the late Will C. Hogg, Houston, Texas. The major objective of the university's board of regents. The major objective of the fund is the establishment of a statewide mental hygiene program under university supervision. Homer P. Rainey, Ph.D., president of the university, announced that the program would include establishment of mental hygiene clinics, promotion of mental health lectures at the university and in various parts of the state, provision of mental hygiene instruction in Texas teacher training courses and provision of facilities for research at the medical school in Galveston. It will go into operation as soon as funds are available.

District Meetings.—The Central Texas (Twelfth) District Medical Society met in Cleburne recently. The scientific program included addresses by Drs. Truman C. Terrell, Fort Worth, on "Chemotherapy in the Treatment of Pneumonia"; Arthur C. Scott Jr., Temple, "Total Thyroidectomy," and Eugene V. Powell, Fort Worth, "Advantages of Prooperative Radiation of Breast Malignancies." Drs. Leopold H. Reeves and Holman Taylor, Fort Worth, president and secretary respectively of the Texas State Medical Association, discussed organization activities. Among speakers at a meeting of the Southwest Texas (Fifth and Sixth) District Medical Society, Corpus Christi, recently were Drs. William W. Bondurant Jr., San Antonio, on "Epidemic Myalgia"; Walter G. Reddick, Dallas, "Sulfapyridine in Pneumococcal Infections"; John Harold Turner, Houston, "Evaluation of Operative Procedure for Prostatism," and James D. Casey, San Benito, "Acute Infectious Pancreatitis and Its Etiologic Relationship to Diabetes Mellitus." The program also included a symposium on anesthesia by Drs. Gustav A. Pagenstecher, Walter Herbert Hill and George H. Paschal, all of San Antonio.

VIRGINIA

Appointments to State Health Staff.—Dr. William Grossmann, epidemiologist of the state health department, Richmond, has been appointed director of the bureau of communicable diseases to succeed Dr. Goldsborough Foard McGinnes, who resigned to take charge of a special venereal disease control project in Tennessee. Dr. Jack B. Porterfield, Williamsburg, health officer of the Peninsula district, has been made epidemiologist. Dr. Edward M. Holmes Jr., formerly health officer of Fairfax County, has been appointed director of the division of venereal disease control.

Faculty Changes at Medical College.—New appointments at the Medical College of Virginia, Richmond, include Dr. Richard W. Fowlkes, Richmond, as associate professor of dermatology and syphilology, and Patrick H. Drewry Jr., Petersburg, as assistant professor of neuropsychiatry. The following promotions have also been announced: Dr. Carrington Williams, Arthur S. Brinkley and Frank S. Johns to be professors of clinical surgery. Dr. Oscar B. Darden, associate professor of neuropsychiatry. Dr. John S. Horsley Jr., associate professor of surgery. Dr. Howard R. Masters, associate professor of surgery. Dr. Henry S. Stern, associate professor of pediatrics. Dr. Harry Walker, associate professor of pediatrics. Dr. Louise F. Galvin and Samuel A. Anderson Jr., assistant professors of pediatrics. Dr. Harry J. Warthen Jr., associate professor of surgery and history of medicine. Dr. George Z. Williams, associate professor of pathology. Dr. Harvie DeJ. Coghill, assistant professor of pediatrics and neuropsychiatry. Dr. Charles L. Outland, assistant professor of preventive medicine.

CANAL ZONE

Society News.—Dr. Oswald S. Lowsley, New York, addressed the Medical Association of the Isthmian Canal Zone August 31 at the Gorgas Institute, Panama City, on "New Developments in Operative Urology." Dr. Lowsley also addressed the Medical Association of Panama September 1 on "Further Experiences with a Plastic Operation for the Cure of a Certain Type of Impotence."

GENERAL

International Meeting on Rheumatism.—The Seventh International Congress on Rheumatism will be held in New York, Boston and Philadelphia June 1-10, 1940. Subjects for discussion will be infection, nutrition and treatment. Information may be obtained from the International Bureau, Keizersgracht 489, Amsterdam.

National Hearing Week.—The American Society for the Hard of Hearing has designated the week October 22-29 as the twelfth annual National Hearing Week. The society and its 170 local organizations will conduct an intensive campaign of public education, emphasizing the prevalence of hearing loss, the need of discovering incipient cases of deafness and the social and economic needs of those who already have a loss of hearing. President Roosevelt recently endorsed the work of the society in a letter to its president, Dr. Austin A. Hayden, Chicago.

Society News.—Dr. William P. Shepard, San Francisco, was made president-elect of the Western Branch of the American Public Health Association at the annual meeting in Oakland in July. Dr. Frederick D. Stricker, Portland, Ore., was installed as president. Dr. Martin S. Kleckner, Allentown, Pa., was elected president of the American Proctologic Society at its recent annual meeting and Dr. A. W. Martin Marino, Brooklyn, vice president. Dr. Curtice Rosser, Dallas, Texas, was reelected secretary. The 1940 meeting will be held in Richmond, Va., June 9-11.

Second Pharmacopeia Supplement.—The Second U. S. Pharmacopeia XI Supplement containing new monographs for many substances and a revision of eighty-five monographs of the original U. S. P. XI is now available. A feature of the new supplement is a cumulative index that lists all U. S. P. titles and indicates where the present official monograph now in force may be found. Orders should be sent, accompanied by a check or money order, to the General Agent, Mack Printing Company, Easton, Pa. The price of the First U. S. P. XI Supplement is \$1 and of the Second U. S. P. XI Supplement, which is considerably larger, is \$1.50.

Conference on Nursery Education.—The biennial conference of the National Association for Nursery Education will have a special health session at its meeting in New York October 25-28 at the Hotel Pennsylvania. Speakers at the health session will be Mary Swartz Rose, Ph.D., Columbia University, New York, a member of the Council on Foods of the American Medical Association, on "Recent Trends in Nutrition Related to Child Development" and Dr. Harold C. Stuart, Harvard Medical School, Boston, "Significant Factors in the Appraisal of the Health of the Young Child." At other sessions Mrs. Jean MacFarlane, University of California, Berkeley, will report on "Implications of a Growth Study of 200 Children" and Dr. Mabel C. Hushka, New York, on "Recent Findings on the Physical Development of Young Children."

American Hospital Association.—The annual meeting of the American Hospital Association will be held in Toronto, Canada, September 25-29. Among the speakers will be: Dr. Alfred K. Haywood, Vancouver, B. C., "Should the Social Service Department Interview All Hospital Patients?" Dr. Frederick F. Tisdall, Toronto, "Nutritive Requirements of the Patient During Disease and Convalescence." Dr. Edwin L. Harmon, Valhalla, N. Y., "The Use and Abuse of the Hospital Pharmacy." Rev. Alphonse M. Schwitalla, St. Louis, "The Place of the General Hospital in the Hospital Field." Dr. Claude W. Munger, New York, "Hospitals and Government in the United States." Michael M. Davis, Ph.D., New York, "Trends in Payment for the Patient Care in Voluntary Hospitals." Dr. Alan Brown, Toronto, "How the Children's Hospital Can Best Meet Community Needs." Dr. David E. Robertson, Toronto, "Surgical Treatment of Infantile Paralysis." Dr. Samuel Proger, Boston, "Helping Hospitals and Practitioners in the Tuberculosis section there will be symposiums on 'Tuberculosis as an Occupational and Compensable Disease,' 'Safeguarding Hospital Personnel from Tuberculosis' and 'Adequate Institutional Care for the Tuberculous.'"

Bequests and Donations.—The following bequests and donations have recently been announced:

The Cincinnati Antituberculosis League, \$2,000 from the estate of the late Mrs. George B. Cox to finance a program of postgraduate work in tuberculosis for Negro physicians and nurses.

Hahnemann Hospital, \$3,000, and St. Luke's and Children's Hospital, \$2,000 from the will of Miss Emily Blackburne as gifts to Dr. John W. Frank, Philadelphia; also \$1,000 to Children's Hospital.

Woman's Medical College of Pennsylvania, Philadelphia, \$3,000 for a chair of anesthesia by the will of Elizabeth S. Hague.

Delaware County Hospital, Drexel Hill, Pa., about \$6,000 by the will of Mrs. Mary E. Kirkpatrick.

Oneida City Hospital, Oneida, N. Y., \$10,000; Children's Hospital Home of Utica, \$10,000; St. Elizabeth Hospital, Utica, \$5,000, and Faxton Hospital, Utica, \$5,000 by the will of the late Mrs. Elizabeth R. Fitch.

Lenox Hill and Presbyterian hospitals, New York, \$5,000 each by the will of the late August E. Vihlein.

Good Samaritan Hospital, Portland, Ore., \$50,000 by the will of Nellie Stevens Wilcox.

St. Luke's Hospital, New York, about \$145,000 from the estate of Mrs. Annabella Curtis, widow of the late Dr. B. Farquhar Curtis.

Hahnemann Medical College and Hospital, Philadelphia, won a \$30,000 claim against the estate of Miss Laura Allen in settlement of a pledge said to have been made by her in 1927. She also left \$30,000 in trust to the Broad Street Hospital.

Sanatorium Association of Philadelphia, \$100,000 and a share in the residuary estate by the will of the late Mrs. Mary A. Combs.

Children's Hospital of Philadelphia will receive about \$6,300 as residuary legatee under the will of Mrs. Caroline M. Bond.

St. Luke's and Children's Hospital, \$3,000, and Methodist Hospital, the income from a \$5,000 trust bequest, by the will of Miss Mary Zehnder. Both hospitals are in Philadelphia.

Philadelphia Shriners Hospital for Crippled Children, \$25,000 by the will of Henry Dolfinger, Norristown.

Methodist Hospital and Hospital of the Protestant Episcopal Church, Philadelphia, and Children's Seashore House, Atlantic City, \$5,000 each by the will of Mrs. Ida M. Vare.

Shriners Hospital for Crippled Children, Chicago, about \$60,000 from the estate of the late U. J. Herrmann.

American Academy of Ophthalmology and Otolaryngology.—The forty-fourth annual convention of the American Academy of Ophthalmology and Otolaryngology will be held at the Palmer House, Chicago, October 8-13 under the presidency of Dr. George M. Coates, Philadelphia. There will be one general session Monday morning and succeeding mornings will be devoted to instructional courses. Section meetings will be held in the afternoons. At the general session Dr. Coates will deliver his official address and Dr. Burt R. Shurly, Detroit, will be introduced as the guest of honor and will make an address. There will be a symposium on "Essential Hypertension," presented by Drs. Albert C. Furstenberg, Ann Arbor, Mich., speaking from the standpoint of otolaryngology; Henry P. Wagener, Rochester, Minn., ophthalmology, and Roy W. Scott, Cleveland, the internist. Among speakers scheduled for the section meetings are:

Prof. Joseph Igersheimer, Istanbul, Turkey, The Optic Nerve and Diseases of Hypertension.

Dr. Arthur DeSa, Pernambuco, Brazil, Ethmoiditis.

Drs. Bennett Y. Alvis and Meyer Wiener, St. Louis, A New Technic for Corneal Transplantation by Means of a Uniform, Mechanically Obtained, Beveled Graft.

Dr. William M. Muncy, Providence, R. I., Relationship of Vitamin Deficiency to Trypsinamide Reaction.

Dr. Otto Jason Dixon, Kansas City, Mo., A New Plastic Operation for the Relief of Conductive Deafness.

Dr. Frank J. Novak Jr., Chicago, Innocuous Oils Useful in Rhinologic Practice in Contrast to the Use of Hydrocarbon Oils.

Dr. Arthur W. Proetz, St. Louis, The Effects of Tobacco (Smoking) on the Respiratory Tract.

There will also be a program of motion pictures each afternoon alternating for the two specialties. The annual banquet will be Wednesday evening and alumni dinners Tuesday evening.

CANADA

Dr. Best Receives Baly Medal.—Dr. Charles H. Best, professor of physiology, University of Toronto Faculty of Medicine, has been chosen to receive the Baly Medal of the Royal College of Physicians of England, *Science* reports. This medal is awarded in alternate years to the person considered to have distinguished himself most in the field of physiology in the preceding two years. Dr. Best's work has dealt with insulin, carbohydrate metabolism, histamine, choline and recently heparin.

Personal.—Dr. Morley S. Loughheed has been appointed health officer of Winnipeg, Man., to succeed Dr. Alexander J. Douglas, who is retiring after nearly forty years of service. Dr. Loughheed has been city bacteriologist for several years. —Dr. Herbert C. George, Regina, Sask., has been appointed medical director of cancer services for the Saskatchewan Cancer Commission and director of the Regina Cancer Clinic, and Dr. Allan W. Blair, Toronto, has been made supervisor of radiotherapy for the commission and radiotherapist of the clinic.

Deaths in Other Countries

Dr. Heinrich William Poll, for many years professor of anatomy at the University of Berlin and the University of Hamburg, died of coronary thrombosis June 12 in Lund, Sweden, aged 61. Mrs. Poll, also a physician, remained in Germany, and it is reported that she died by suicide August 5. Dr. Poll delivered the Flexner Lectures at Vanderbilt University, Nashville, Tenn., and lectured at other universities in the United States during the winter of 1928-1929. His studies were principally in physical anthropology, the endocrine glands and genetics.

CORRECTIONS

Dr. Rector Presided at Wisconsin Meeting.—In a notice of the annual meeting of the State Medical Society of Wisconsin September 13-15 in *THE JOURNAL*, September 2, page 951, it was said that the meeting would be "under the presidency of Dr. Raymond G. Arveson, Frederic." Dr. Albert E. Rector, Appleton, was the president for this meeting and Dr. Arveson was to be installed September 13 as president for the coming year.

Review of Clinical Gastroenterology by Dr. Horace W. Soper.—In the review of this book published in *THE JOURNAL*, September 2, the statement is made that some of the pictures represent reproductions of films of the late R. Walter Mills, and it is further stated that the author does not so designate. The author, Dr. Horace W. Soper, calls attention to the fact that credit is given to Mills on pages 60, 126, 150, 240 and 274.

Government Services

Changes in the U. S. Public Health Service

Dr. Joseph W. Mountin, senior surgeon, U. S. Public Health Service, has been relieved from his assignment in charge of public health methods at the National Institute of Health, Bethesda, Md., and detailed as assistant surgeon general in charge of the division of domestic quarantine. He succeeds Assistant Surgeon General Clifford E. Waller, who has been assigned to duty in the surgeon general's office in charge of the general inspection office. Drs. Walter L. Treadway and Joseph Bolten have been promoted from the grade of senior surgeon to that of medical director.

The Wellcome Medal

The Association of Military Surgeons of the United States announces the annual competition for the Wellcome Gold Medal and cash prize of \$500, awarded "for researches, discoveries, inventions, designs, improvements, essays, or any other acts or deeds which the executive council of the association may consider desirable and helpful to the objects of the association, and relating to any phase of medico-military affairs and disease control associated with the army, navy, militia and public health and marine hospital service in times of peace or war at home or abroad." The competition is open to any member of or person eligible for membership in the Association of Military Surgeons of the United States. Additional information may be obtained from the secretary of the association, Army Medical Center, Washington, D. C.

Examination for the Regular Army Medical Corps

The War Department announces an examination December 4-8 for candidates for appointment as first lieutenants in the Medical Corps, Regular Army, to fill vacancies during the next fiscal year. The examination is open to all male graduates of acceptable medical schools who have completed one year's internship in an approved hospital and who will not be over 32 years of age at the time it will be possible to tender a commission. Boards of medical officers convened throughout the United States will conduct the examination, which will consist of a physical examination in professional subjects and a determination of the candidate's adaptability for military service. Full information and application blanks may be obtained from the Adjutant General, War Department, Washington, D. C. Applications will not be considered after November 18.

Foreign Letters

LONDON

(From Our Regular Correspondent)

Aug. 19, 1939.

The War on Nerves

In an address to the National Council for Mental Hygiene entitled "Some Emotions and a Moral," Sir Walter Langdon-Brown said that if we were not at war we were not at peace. The production of nervous attrition was being followed deliberately as an aggressive policy in certain countries, and therefore new methods of defense were necessary. To insist, as some communities did, on utter obedience to the force of authority apparently simplified the task of coordinating units into a coherent whole, but at what ultimate cost to the nation and to the individual? Undue repression in the individual life, whether autonomous or imposed by parental or scholastic authority, made for psychosis and perversion, and a parallel could be drawn between the psychoneuroses of individuals and nations.

The motive force of fear was originally a defensive mechanism, but when fear became unreasoning it was a perversion of this mechanism. The sympathetic nervous system, which superintended many of the functions of organic life, retained some of the primitive features of the nervous system of the lower animals. The condition of continued fear, whether recognized or not as such by the sufferers, was capable of producing the symptoms of which they complained. Why did the neurotic individual refer so many of his symptoms to disorders of various organs? Emotional disturbance led to widespread preparation for imminent activity. The activity never found its occasion, but the disturbance persisted. In the international situation we now saw a deliberate attempt to exploit mass psychology by manifold suggestions calculated to excite fear and evoke a defeatist attitude. Fear was closely associated with the same nervous mechanisms as prepared the body for action and was intensified if action did not result. If fear could be mobilized into defensive action, to a large extent it would cease to be felt as fear. The best antidote for this long drawn out war on the nerves was active cooperation in some form of national service.

Nutrition in the British Colonial Empire

The great attention being given to nutrition in Great Britain is not confined to the home country. A report on nutrition in the colonial empire, prepared by a committee of the Economic Advisory Council, has just been published. The committee has no doubt that improved nutrition could bring great benefit, not so much by eradication of disease as by general improvement in the standard of well being. The colonial dietaries are predominantly vegetarian, only small quantities of animal food being consumed in most parts and milk rarely. The diets are low in first class proteins, fats, green leafy vegetables and fruits. Calcium and phosphorus and all the vitamins except vitamin D are widely deficient. The low standard of life, ignorance and prejudice are the causes of prevalent malnutrition.

The remedy is largely one of economic development, which means improvements in agriculture, by which the people predominantly live. Family production of food to meet family needs would be a safeguard against the effects of fluctuations of income from money crops. A combination of cereals and legumes would be valuable and the soya bean is especially recommended for cultivation, as also are groundnuts, red palm oil, fruits and green leafy vegetables. An increase of animal husbandry is desirable. Milk in anything comparable to its use in Western dietaries is not possible. Improvement of fishery might be more important than any other reform. The evil of removing vitamin B in the milling of rice is now an old story, but the report states that even the most highly milled rice may

contain nearly adequate quantities of the vitamin if it is properly stored and cooked. The infant mortality is high in many parts of the colonial empire and one of the main causes is unsuitable feeding. This may be connected with social habits, as in the case of Jamaica, where 71 per cent of the births are illegitimate. The government has now for the first time material for framing a policy which is fundamental to the welfare of the colonial peoples. It has arranged that the local surveys shall be coordinated by staff work under the Medical Research Council.

Government Plans for Food in War Time

War time plans for controlling the nation's food supplies in war by a minister of food, which would work through nineteen regional offices, are complete. They are based on the government becoming the sole purchaser of all imports. Already large purchases of storable food, such as wheat and whale oil, have been made. This action would eliminate speculation, and all food prices, except those of luxuries, will be controlled. Wholesalers would purchase from the government and would operate according to orders. Retailers would be registered and licensed by one of the 1,400 local committees already appointed. They would purchase from wholesalers at prescribed prices regular weekly supplies and sell to the public at prices fixed by order, which would leave a fair margin of profit. Immediately on the outbreak of war, five staple classes of commodities would be rationed. They are (1) butcher's meat, (2) butter and margarine, (3) bacon and ham, (4) lard dripping and other cooking fats and (5) sugar. In case of emergency 19 million household application forms and 60 million ration cards are already printed. A more detailed scheme is being worked out providing for additional rations for certain classes of workers. Food committees controlling the local arrangements could be established at a few hours notice. It is reckoned that ten days would be required to transfer private trading to the government controlled system. Afterward shipment and buying would be entirely in the hands of the government. Existing importers would continue to handle imports, but as agents for the government. Factories would also operate under direction. Two of London's biggest markets—Smithfield (meat) and Billingsgate (fish)—would be closed immediately on the outbreak of war and their functions transferred to railheads on the outskirts of London. Special arrangements are being made for the feeding of the population to be evacuated from the cities and towns to safer areas. Already forty-eight hours' free supply is ready, which would give traders time to make the necessary adjustments in reception areas. This supply consists of canned beef, condensed milk, biscuits and chocolate. The huge reserves now stored include sufficient wheat until the next harvest.

Spontaneous Rupture of the Gallbladder

Perforation of the gallbladder from inflammatory changes associated with gallstones is relatively common, but massive hemorrhage is so rare in such cases that, since the first case reported to the Pathological Society of London in 1858 by Leared, only four similar cases have been recorded. The last was reported by the Bartletts of St. Louis in *THE JOURNAL* Feb. 22, 1936. A sixth case has just been reported by Mr. Robert Mailer of Glasgow (*Brit. J. Surg.* 27:91 [July] 1939). A retired policeman, aged 65, was admitted to the Victoria Infirmary with the diagnosis of intestinal obstruction. Up to a week before he had been in excellent health. He then began to suffer from vague abdominal pain, which did not prevent him from going about as usual. On the day before admission, pain in the lower part of the abdomen became more severe and he vomited brownish material. He suffered from constipation, no flatus was passed, and some abdominal distention was present. There was slight cyanosis round the lips. The tongue was furred and the abdomen slightly distended and tender in the lower half, and there was diffuse resistance to palpation.

Rectal examination was negative. As there was no response to two enemas the abdomen was opened. It contained from 3 to 4 pints of partly clotted blood. The intestinal loops were moderately distended but there was no obstruction. The source of hemorrhage was found to be a 1 inch rent in the fundus of the gallbladder. There was a large gallstone. As the patient's condition was precarious, a tube was passed through the rent and the gallbladder was packed round with gauze and the abdomen hurriedly closed with sutures. The patient died three hours later. At the necropsy the wall of the gallbladder was found thickened and hemorrhagic, and near the perforation it was necrotic. The pathologic picture was one of hemorrhagic infarct of the gallbladder wall due to interference with the venous return by the pressure of a large gallstone.

The Journal of Endocrinology

The large and rapidly increasing publicity work on endocrinology by British investigators has made it desirable to bring together in a single British journal papers now scattered over many different periodicals. A new publication, the *Journal of Endocrinology*, has therefore been founded under a Council of British endocrinologists (P. M. F. Bishop; Prof. F. A. E. Crew, F.R.S.; Sir Henry Dale, F.R.S.; Prof. E. C. Dodds; Prof. C. R. Harrington, F.R.S.; Prof. G. E. Marrian; Dr. F. H. A. Marshall, F.R.S.; A. S. Parkes, F.R.S.; Dr. F. G. Young, and Dr. Solly Zuckerman). Professor Dodds is the editor and Dr. R. L. Noble the assistant editor. The *Journal* will be published quarterly by the Oxford University Press, Amen House, Warwick Square, London, E. C. 4. The address of the American branch is 114 Fifth Avenue, New York. The annual subscription is \$30. The first number runs to 116 quarto pages and is well illustrated. The titles of the articles show that the intensely active subject of endocrinology is being well covered.

Bureau of Hygiene of the League of Nations

If the League of Nations is dissolved for political reasons, means ought to be found to retain several functions of this organization, among them the International Bureau of Labor and the Bureau of Hygiene. If the Bureau of Hygiene did not exist, to adopt Voltaire's words, one ought to invent it, for it centralizes not only all that concerns the science and teaching of hygiene but all the practical applications as well. For this reason four great nations that have severed their connection with the league have nevertheless asked to be allowed to continue their participation in the health services which it directs. Parisot of Nancy, chairman of the committee on hygiene, recently emphasized the fact that, far from being discouraged by the resignations from the league, induced by national rivalries, the committee on hygiene ought to redouble its efforts, because the peoples of these nations need the close cooperation between science and sociology that transcends political ideologies and national conflicts. Professor Turumi, following Japan's resignation from the League of Nations, had to relinquish his functions as chairman. Dr. Rajchmann, who had rendered eminent services since his nomination in 1921, withdrew on reaching the retirement age.

Among the topics discussed at this meeting the fight on cancer was first. A special committee was created for this purpose. The Bureau of Hygiene will also participate in the Pan-African Conference on Sanitation to be held next year at Nairobi. At the request of nineteen countries, it will also call an intergovernmental conference on antimalarial therapies to meet next year. In consequence of Professor Madsen's discussion of the incidence of tuberculosis among medical students, the need of studying the health of university students was stressed.

Alcoholic Coma in Children

Alcoholic coma in children is not so infrequent as one would suppose. Debré reported two cases to the Society of Pediatrics. The first concerned a child aged 4 years who rapidly swallowed more than a pint of red wine. He fell into a heavy torpor with dyspnea, edematous rales and stertor. Diagnosis indicated postepileptic coma and hypoglycemia, until the empty bottle was found. Gastric lavage was resorted to, followed by symptomatic treatment. The intoxication passed off on the third day without effects. The other child was 9 years old and had swallowed two large glasses of wine. Analogous symptoms occurred except that the coma was preceded by violent agitation. The child recovered in response to similar treatment. A peculiarity of these intoxications was that the breath of the children did not smell of alcohol or wine, which made the detection of the cause more difficult.

Prognosis, however, is far from being always favorable. Gênévri and Fèvre at the same meeting cited two cases in which the cure was uncertain. A child aged 3 years had drained all bottles left over from a banquet and even smoked ends of cigarettes scattered on the table. Besides coma he manifested vomiting, loose and sanguineous stools and intussusception. An operation was followed by icterus, vomiting and violent agitations. The child, however, completely recovered. The other child had become intoxicated through excessive doses of rum therapeutically given. Recovery was slow. A fatal dose would contain 7 cc. of pure alcohol per kilogram. In the cases mentioned the alcohol content did not exceed 2 cc. Intubation is the treatment of urgency and is confirmatory, at the same time, of the diagnosis.

University News

The following appointments are announced at the Faculty of Medicine of Paris: Dr. Aubertin, professor of therapeutics; Dr. Henri Bénard, professor of experimental pathology; Dr. Lévi Valensi, professor of the history of medicine, and Dr. Velter to the chair of ophthalmology.

Prof. André Hovelacque, head of the department of anatomy at the Faculty of Medicine of Paris and son of the anthropologist, has just died.

Prof. René Frölich, who has taught pediatric surgery at Nancy for forty years, has retired.

Aug. 3, 1939.

Alcohol, Tobacco and Coffee

A report was made in the Berlin letter of April 10 (THE JOURNAL June 3, p. 2339) regarding a nationwide meeting on public health and stimulants. Here are a few interesting additional items. Professor Reiter, president of Germany's department of public health, read a voluminous paper on stimulants and efficiency. His definition of "addiction" was so vague that it scarcely commends itself. He said "One may speak of 'addiction' whenever the inhibitions against the use of a stimulant fail. Such inhibitions concern the individual, his family and the public; their failure harm all." He said "Alcoholism affects mostly the age level of 35-54, especially the 35th to the 44th year. In individual diseases accompanied with inability to work alcoholic persons show excess in relation to the normal rate (100) in the following proportions: nervous diseases, 400; organs of movement, 286; organs of digestion, 285; organs of circulation, 273; accident, 258. General incidence of disease among alcoholic persons (normal rate 100) is indicated by the following figures: 15-24 years, 180; 25-34 years, 264; 35-44 years, 283; 45-54 years, 261; 55-64 years, 266; 65-74 years, 293. Abuse of alcohol leads to increased occupational accidents. For example, 171.4 accidents were reported per thousand insured workers employed in breweries. This represents the highest

accident rate for industries. According to the most recent reports of the central traffic department of the government for 1938, of all automobile drivers' licenses withdrawn, 9,069 in number, 4,307 were withdrawn on account of intoxication. He further stated that of late years degenerative and histologic modifications were observed in the scrotal tissues of habitual drinkers, observations that the government was planning to follow up. Reiter then inveighed against the use of tobacco. Injury to health and lessening of efficiency have become of late more manifest. Use of tobacco clearly affects and lowers the mental ability of youthful persons. Physical achievement is also disturbed; tobacco at first heightens it and then induces an abrupt descent. Examinations for military service of adolescents of 19 to 20 years of age revealed physical defects in a large number. Reiter also called attention to the close connection between cigaret smoking and physical and mental susceptibility to disease and the disturbances of the normal sexual life. Abuses of this kind, he said, would be vigorously combated by the government, as well as "the increasingly shameless methods of advertising."

The first effective measure in this direction was taken by Goering, commander-in-chief of aviation, with the publication of a decree affecting military fliers. Without seeking to condemn all use of alcohol and tobacco, he announced the following prohibitions: the opening of "bars" for the consumption of liquor within the limits; standing or sitting around tables where alcoholic beverages are dispensed; selling whisky to soldiers already intoxicated; consumption of alcohol immediately before and during duty, especially duty on airplanes and automobile service; sales of foreign wines within the precincts; smoking on village streets, on marches and in brief periods off duty; the sale of foreign tobacco merchandise; keeping casinos and canteens open beyond locally permitted hours (prohibitive also for officers); company festivities in rooms and homes. Similar orders have been issued to the army and navy. They are mandatory also when the soldier is in civilian clothes.

As to coffee, Goebbels wrote an article in the *Völkischer Beobachter* in which he stigmatizes the use of coffee as an unpatriotic act. He clearly appeals to economic, not to hygienic, considerations. As a matter of fact, the per capita consumption of coffee in Germany is already lower than that of other countries. That all these restrictions are primarily concerned with questions of money and not with public welfare is evidenced by the quotation from Goering's decree: "Moreover, in restricting the use of alcohol and nicotine, we make economies in foreign exchange which we need more imperatively for other new materials." Utterances like these revive the memory of the governmental propaganda, conducted a few years ago when the new régime first came into power, against lemons as a "wanton fruit of the south" and of the recommendations of indigenous fruits.

The Nicotine Content of Tobacco Products

New regulations have been published defining the presence or absence of nicotine in tobacco. Only such cigarets, cigaret tobacco and pipe tobacco may be designated as possessing a low nicotine content which do not have more than 0.6 per cent of nicotine (in its dry state); likewise cigars and cigar tobacco with no more than 0.8 per cent nicotine content. The term "free from nicotine" may be applied to tobacco and cigars with no more than 0.1 per cent and to cigarets with no more than 0.2 per cent of nicotine (in its dry state). Tobacco and tobacco products may be designated as "naturally of low nicotine content" or "naturally free from nicotine" if they are indebted for the low nicotine content required by law solely to the use of tobacco leaves so cured as to present these characteristics. If, in consequence of special additions or measures, less nicotine finds its way into the smoke, the following designations may be permitted: tobacco "free from nicotine in the smoke" if the nicotine content of the smoke does not exceed 0.3 per cent; cigarets and pipe tobacco "with low nicotine smoke content" if they do not possess more than 0.17 per cent of nicotine; cigars, if they contain no more than 0.1 per cent (interpreted as applying to the amount of tobacco consumed having a water content of from 8 to 10 per cent). Only such preparations may be advertised or put into circulation as means to reduce the nicotine content in the smoke as are effective in removing at least 50 per cent of the nicotine that appears in the smoke in normal average tobacco. The following terms are especially to be regarded as "misleading": statements like "weak in nicotine," "nicotine neutral," "free from poison," "poison removed"; likewise (apart from the instances mentioned) all designations and statements calling attention to a low nicotine content; likewise all numerical references relating to the nicotine content so far as they are not expressly permitted; finally, expressions calling attention to the use of tobacco in promoting health or as containing nothing in any way hygienically objectionable.

According to investigations undertaken last year by Germany's department of health, no brand of cigaret showed a nicotine content under 7 per cent. It would seem that the new regulations sound the knell of cigarets advertised as "low in nicotine." Some firms have been able to reduce the nicotine content by blending specially selected tobaccos. Within the last years not more than about twenty brands really or allegedly low in nicotine appeared on the German market, but only about three of them are likely to possess a nicotine content of less than 8 per cent. The extent to which cigarets low in nicotine are sold is often overestimated and may not rise above 4 per cent of the total tobacco consumption. It is questionable in view of the more rigorous regulations whether brands "low in nicotine content" will appear at all in trade. Tobacco manufacturers may not advertise their products as health promoting nor represent the use of tobacco as a sign of manliness nor ridicule opponents of tobacco. They may not make advertising appeals to women and those interested in sports nor picture smokers at the wheel of the automobile.

Beta Carotene and Vitamin A in Whales

K. H. Wagner presented a report before the Biological Society in Leipzig of his exploratory trip to the Danish Faroe Islands (situated between Norway and Iceland), which he undertook in behalf of Professor Scheunert, nutritional physiologist of Leipzig, for the purpose of vitamin research on whales. Investigations of all organs of freshly killed whales (blue whales, fin whales and sperm whales) to determine vitamin A and beta carotene content, were conducted at the whaling station of Lopra by means of chemical and physical methods. The organs of the same species were found to possess an almost constant vitamin content; between the different species certain variations occurred. Difference of sex played no part in vitamin content. On the other hand, the vitamin content of the animals' organs increased with age. Vitamin A was regularly found in the liver, heart, kidney, muscles, flesh and blubber but not always in the lung and spleen. Its content in the blood, milk and urine was nearly regular. The following observations in blue and fin whales may be of interest: The vitamin A content of the muscle, indicating 300 international units, was no higher on the average even in the musculature of the heart. In the case of the spleen and lung, the values fluctuated between 0 and 250 international units. To explain these great differences, Wagner referred to the difference in blood content of the organs. The high vitamin A content of the blubber was noteworthy, on an average 17,000 international units per hundred grams. Most richly supplied with vitamin A, amounting to 10,000 international units per gram, was the liver. In two pregnant fin whales the thickness

of the blubber was surprisingly below normal (far over half) and the vitamin A content of the blubber was also less by more than one half. The vitamin content in the other organs corresponded to those of nonpregnant animals. Attention was specially directed to the vitamin A content of the thyroid gland. The normal average of 300 international units rose in pregnancy fivefold and more (from 1,470 to 1,720 international units in a thyroid gland of 100 Gm.). The thyroid gland, therefore, plays a significant part during pregnancy in vitamin A metabolism; on the other hand, the vitamin A content of the liver of pregnant whales fell. Also in the case of suckling females the content of the thyroid gland was 300 per cent higher (860 international units) than the normal average. The sperm whales possessed a much greater vitamin A content than the other two species. The values found in lung, spleen, kidney and pancreas of 100 Gm. ranged from 1,100 to 2,000 international units. Even in the heart, average values of 1,700 international units could be discovered. Likewise the average content of the blubber in sperm whales, amounting to 20,000 international units per hundred grams, exceeded that of the blue and fin whale. The highest content of vitamin A was found in the liver of the sperm whale (28,000 international units to a gram). At present the vitamin A content of whales is not being utilized therapeutically.

STOCKHOLM

(From a Special Correspondent)

Aug. 15, 1939.

Poliomyelitis Research

Prof. C. A. Kling, director of the state bacteriologic laboratory in Stockholm, is engaged in collecting and sifting the records of some 8,000 cases of infantile paralysis which occurred in Sweden in the period 1933-1938. With information on the geographic and chronologic distribution of these cases, it is hoped that valuable light may be thrown on the association, if any, of the disease with certain waterways. Information may also be forthcoming with regard to regional immunity, endemic foci, the part played by healthy carriers, and the reservoirs of the disease at periods when it seems to have died out. These investigations will require the aid of well qualified statisticians. The use and the misuse of statistics have lately been warmly debated in connection with poliomyelitis research. Dr. Jönsson's statistical study of the incidence of poliomyelitis in Sweden led him to challenge the accepted opinion that poliomyelitis is essentially a disease of rural communities in thinly populated areas. His conclusion that the disease is in reality just as frequent in cities has raised a hue and cry against him. Dr. Wernstedt, an authority on the epidemiology of poliomyelitis and one of the founders of the doctrine which classes poliomyelitis as an essentially rural disease, pounced on Dr. Jönsson at a meeting of the Swedish Medical Society and in the medical press. Dr. Jönsson, it would seem, has combined an inadequate clinical and epidemiologic knowledge of poliomyelitis with a faulty interpretation of statistical technic. So much for Dr. Wernstedt's opinion of Dr. Jönsson's work. In the opinion of Professor Kling and many other Swedish authorities there can be no doubt as to the comparative liability of rural communities to suffer from poliomyelitis.

Better Wells for Rural Communities

Prince Carl, brother of the king of Sweden and president of the Swedish Red Cross Society, announced at the annual meeting of this body that it is about to engage on a campaign for better wells and drinking water in rural areas. Surveys in this field have shown a great need for reform. Dr. A. Bergstrand has inspected some 400 wells in the rural district to which he is attached, and in between 20 and 30 per cent he found that the well curbs were of poor quality, rotten

wood. In only 12 per cent of all the wells did they communicate by a pipe with the kitchen of the house. Another survey, conducted by Dr. C. A. Yllner, has dealt with the whole country, questionnaires being sent to the public health authorities of urban and rural communities. A surprising outcome of this investigation is that even in certain large cities the drinking water was not provided under absolutely reliable public health conditions. As for the municipal communities, mainly rural, it was the exception rather than the rule to find adequate provision made for the purification of the surface water. It would seem, therefore, that the contemplated educational campaign should be directed not only to the farmer but also to certain engineers and other public health officials responsible for the supply of water to cities.

The Late Professor Josephson

The death, May 10, of Prof. Carl David Josephson marked the passing of a great personality in the Swedish medical world. Born in 1858 in Stockholm, here he passed the last years of his life after having spent many of them in Uppsala. His family, which migrated into Sweden from Brandenburg more than a century ago, has been prolific in men who have made their mark in the history of Sweden. He was not yet 30 when he published a mature study of ureterogenital fistulas in women. This was the forerunner of a series of important gynecologic and obstetric studies the publication of which was continued throughout his long professional career. He was quick to realize that an obstetrician and gynecologist is apt to be left handed, metaphorically speaking, if he does not master the manipulative side of surgery. So he perfected operative technic. He also explored the field of pediatrics, in which he came to be recognized as an authority. Thus equipped he acquired an extensive and remunerative practice in Stockholm, where he would doubtless have remained if the amassing of a fortune had been his chief aim in life. But in 1909 he was invited by the University of Uppsala to succeed Professor Lindfors, and in duty bound he did not refuse. Here he continued to develop his gynecologic and obstetric interests and to publish at home and abroad one communication after another on these subjects. The treatment of cystitis with silver nitrate irrigation, conservative renal surgery, the radiologic diagnosis of renal tuberculosis, the treatment of prolapse of the uterus, cesarean section and the treatment of lesions of the peritoneum were among the subjects to which he devoted special attention.

Marriages

FRANCIS PATTERSON WELLS, first lieutenant, M. C., U. S. Army, to Miss Alice Hobson Haynes of Washington, D. C., July 1.

HAROLD SAMUEL WRIGHT, Norwood, N. Y., to Miss Ruth Elvira Barclay at South Orange, N. J., June 8.

ANDREW J. TOMAN, Chicago, to Miss Emily Marianne Serhant of Berwyn, Ill., in Oak Park, Ill., in June.

DENSMORE THOMAS, Niles, Ohio, to Miss Dorothy Yarbrough of Winston-Salem, N. C., in July.

CARL GIFFORD WHITBECK, Hudson, N. Y., to Miss Virginia Loftin of Washington, D. C., July 1.

WILLIAM S. WALDRON, Yonkers, N. Y., to Miss Betty Gabriel of Savannah, Ga., July 11.

JOHN MILES KRUPKA, Berwyn, Ill., to Miss Evelyn Phyllis Kotrba in Chicago, August 2.

HOMER D. UNDERWOOD, Cleveland, to Miss Irene E. Merten of Lorain, Ohio, in July.

LEWIS K. TESTER, San Angelo, Texas, to Miss Ophelia Hurd of Bowie, June 1.

JOSEPH E. WALTON, Homer, Ill., to Miss Wanda Lee Lorton of Shumway, June 12.

MARY RUTH JACKSON to Mr. Dan McClung, both of Dallas, Texas, July 1.

Deaths

Louis Henry Fligman, Helena, Mont.; University of Minnesota College of Medicine and Surgery, Minneapolis, 1901; vice president and past president of the state board of health; member and past president of the Medical Association of Montana; governor and fellow of the American College of Physicians; consulting internist to the Veterans Administration Facility; past president and secretary of the Lewis and Clark County Medical Society; lieutenant commander, Medical Reserve Corps of the United States Navy; aged 60; internist to St. John's Hospital and St. Peter's Hospital, where he died, July 14, of complications following an operation for appendicitis.

Howard McIlvain Morton, Vincentown, N. J.; University of Pennsylvania Department of Medicine, Philadelphia, 1891; fellow of the American College of Surgeons; past president of the Minnesota Academy of Ophthalmology and Otolaryngology; professor of diseases of the ear and eye, Hamline University, 1893-1895; served during the World War; at various times on the staffs of the Minneapolis General, St. Barnabas, Fairview and Swedish hospitals, Minneapolis; aged 71; died, July 19, of Hodgkin's disease.

John Andrew Murphy, Philadelphia; University of Pennsylvania Department of Medicine, Philadelphia, 1903; member of the Medical Society of the State of Pennsylvania; assistant professor of clinical immunology at the Medico-Chirurgical College, Graduate School of Medicine, University of Pennsylvania; served during the World War; on the staffs of the Presbyterian and the Germantown hospitals, Philadelphia, and the Abington (Pa.) Memorial Hospital; aged 59; died, June 13.

Walter Stuart Galbraith, Lethbridge, Alta., Canada; McGill University Faculty of Medicine, Montreal, Que., 1899; past president of the Council of the College of Physicians and Surgeons of the Province of Alberta, and the Alberta Medical Association; formerly mayor and member of the school board; fellow of the American College of Surgeons; attending surgeon to the Galt Hospital and St. Michael's General Hospital; aged 72; died, July 16.

William Lane Wilbur Ⓢ Hightstown, N. J.; University of Pennsylvania Department of Medicine, Philadelphia, 1888; president of the state board of medical examiners; health officer and school physician; at one time county sheriff; past president of the Mercer County Medical Society; at one time member of the state legislature; aged 74; died, June 11, in the University of Pennsylvania Hospital, Philadelphia.

Eugene Silas Strout Ⓢ Minneapolis; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1891; an Affiliate Fellow of the American Medical Association; member of the American Academy of Ophthalmology and Otolaryngology; fellow of the American College of Surgeons; on the staffs of the Hillcrest and Northwestern hospitals; aged 76; died, June 25, of coronary occlusion.

John Cook Baldwin Ⓢ Baltimore; Johns Hopkins University School of Medicine, Baltimore, 1915; member of the American Academy of Pediatrics; served during the World War; on the visiting staffs of the Hospital for Women, Johns Hopkins Hospital, Union Memorial Hospital and the Church Home and Infirmary; aged 52; died, July 3, of coronary thrombosis.

Maude A. Bowyer, Philadelphia; Woman's Medical College of Pennsylvania, Philadelphia, 1898; member of the Medical Society of the State of Pennsylvania; for many years physician to the Juvenile Municipal Court and examining physician at the House of Detention; aged 75; died, June 2, in the Misericordia Hospital of carcinoma of the larynx.

William W. Whittington, Snow Hill, N. C.; Louisville (Ky.) Medical College, 1895; member of the Medical Society of the State of North Carolina; past president of the Greene County Medical Society; county physician; veteran of the Spanish-American War; prison camp physician; aged 69; died, June 12, of coronary thrombosis.

Ellis Harvey Andrews Ⓢ Peru, Ind.; Kentucky School of Medicine, Louisville, 1901; past president and secretary of the Miami County Medical Society; for many years member of the county school board; on the staff of the Dukes-Miami County Memorial Hospital; aged 68; was killed, July 17, in an automobile accident.

Arthur Everett Crow Ⓢ Uniontown, Pa.; Jefferson Medical College of Philadelphia, 1903; member of the House of Delegates of the American Medical Association from 1925 to

1927; fellow of the American College of Surgeons; on the staff of the Uniontown Hospital; aged 61; died, June 3, of cerebral hemorrhage.

Frank Staples Bachelder, Pontiac, Mich.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1905; member of the Michigan State Medical Society; formerly secretary of the Oakland County Medical Society; served during the World War; aged 61; died, July 17, of coronary thrombosis.

R. Cloyd Smith, Wichita Falls, Texas; University of Louisville (Ky.) Medical Department, 1893; member of the State Medical Association of Texas; past president of the Wichita County Medical Society; on the staff of the Wichita General Hospital; aged 76; died, June 3, of cerebral hemorrhage.

Gustav Seeligmann Ⓢ New York; Albert-Ludwigs-Universität Medizinische Fakultät, Freiburg, Baden, Germany, 1887; fellow of the American College of Surgeons; consulting gynecologist to the Lenox Hill Hospital and Dispensary and the Lebanon Hospital; aged 78; died, June 21, of leukemia.

Arthur Edward Ardagh, Orillia, Ont., Canada; Trinity Medical College, Toronto, 1888; coroner; at one time president and for many years a councillor of the Ontario College of Physicians and Surgeons; past president of the Orillia Hospital Board; aged 73; died, July 25, of heart disease.

Emerson Ward Hitchcock, Auburn, N. Y.; New York Homeopathic Medical College and Hospital, 1890; member of the Medical Society of the State of New York; on the staff of the Auburn City Hospital; aged 76; died, June 26, of angina pectoris, nephritis and chronic myocarditis.

William H. Rankin, Garden City, N. Y.; Queen's University Faculty of Medicine, Kingston, Ont., Canada, 1889; fellow of the American College of Surgeons; formerly on the staff of St. John's Hospital, Brooklyn; aged 74; died, June 2, at his summer home near Kingston, Ont.

Donald Barton McHenry Ⓢ Danville, Pa.; Jefferson Medical College of Philadelphia, 1915; past president of the Montour County Medical Society; served during the World War; on the staff of the Bloomsburg Hospital; aged 48; died, June 4, of cardiovascular disease.

John Thomas Butler, Brookhaven, Miss.; Bellevue Hospital Medical College, New York, 1880; member of the Mississippi State Medical Association; physician to the Whitworth College for many years; aged 85; died, June 19, in the King's Daughters' Hospital.

Arthur James Ross, Perry, Iowa; College of Physicians and Surgeons, Keokuk, Iowa, 1880; Bellevue Hospital Medical College, New York, 1884; member of the Iowa State Medical Society; aged 82; died, June 19, of injuries received in an automobile accident.

Benjamin Harrison Holmes Ⓢ Racine, Wis.; Marquette University School of Medicine, Milwaukee, 1913; member of the American Academy of Ophthalmology and Otolaryngology; served during the World War; aged 51; died, June 29, of coronary occlusion.

Walter Harry Grimwood, Fort Madison, Iowa; Keokuk Medical College, 1898; served during the World War; for many years a member of the board of education; aged 76; died, June 20, in Rochester, Minn., of chronic cholecystitis with stones.

George McGrath, Hamilton, Mont.; Queen's University Faculty of Medicine, Kingston, Ont., Canada, 1893; member of the Medical Association of Montana; aged 73; on the staff of the Marcus Daly Memorial Hospital, where he died, June 20.

Archibald Stephen Knight, Rochester, N. Y.; Queen's University Faculty of Medicine, Kingston, Ont., Canada, 1897; member of the Medical Society of the State of New York; aged 69; died, June 29, of coronary thrombosis and arteriosclerosis.

John Worth Gray, Oklahoma City; Washington University School of Medicine, St. Louis, 1906; member of the Oklahoma State Medical Association; aged 66; died, June 18, at the Mayo Clinic, Rochester, Minn., of carcinoma of the stomach.

George Michael Flanagan Ⓢ New Britain, Conn.; College of Physicians and Surgeons, Boston, 1911; aged 62; died, June 13, in the New Britain General Hospital of cerebral hemorrhage, hypertensive heart disease and arteriosclerosis.

William Christian Heisey Ⓢ McKeesport, Pa.; Jefferson Medical College of Philadelphia, 1905; served during the World War; on the staff of the McKeesport Hospital; aged 58; died suddenly, June 21, of coronary occlusion.

Henry Jonas Wickert, Milford Square, Pa.; Jefferson Medical College of Philadelphia, 1888; member of the Medical Society of the State of Pennsylvania; aged 76; died, June 8, in the Quakertown (Pa.) Hospital.

John Albert Gillespie, Kingsburg, Calif.; Drake University Medical Department, Des Moines, Iowa, 1888; College of Physicians and Surgeons, Chicago, 1895; aged 77; died, June 14, of intra-abdominal carcinomatosis.

Marshall B. West Ⓢ Catonsville, Md.; University of Maryland School of Medicine, Baltimore, 1901; on the staff of St. Agnes' Hospital, Baltimore; aged 62; died, June 9, of hypertensive cardiovascular disease.

Abram Meyer Zucker, Sharon, Pa.; University of Pennsylvania School of Medicine, Philadelphia, 1923; member of the Medical Society of the State of Pennsylvania; aged 42; died suddenly in June.

Wilburn Jackson Winter, Chattanooga, Tenn.; University of Tennessee Medical Department, Nashville, 1903; member of the Tennessee State Medical Association; aged 66; died, June 5, of coronary occlusion.

Ferdinand Alonzo Wenger, St. Paul; Minneapolis College of Physicians and Surgeons, 1904; formerly on the staff of the West Side General Hospital; aged 63; died, June 6, of coronary sclerosis.

Adele L. Palmitier, Brooklyn; Eclectic Medical College of the City of New York, 1889; member of the American Society of Anesthetists; aged 81; died, June 12, of heart disease and arteriosclerosis.

Leonard Arthur Turner, Shelbyville, Ky.; Kentucky University Medical Department, Louisville, 1906; member of the Kentucky State Medical Association; aged 56; died, June 30, of carcinoma.

Carl Edwin Allison, Wakefield, Mass.; Tufts College Medical School, Boston, 1914; member of the Massachusetts Medical Society; aged 50; died, June 9, in Chelsea of hypertensive heart disease.

Milton Preston James, Brooklyn; Birmingham Medical College, 1911; for many years member of the state tax division of the U. S. Department of Internal Revenue; aged 54; died, June 21.

Charles Trangath Noecker, Waterloo, Ont., Canada; University of Toronto Faculty of Medicine, 1886; medical director of the Dominion Life Insurance Company; aged 74; died, June 16.

Emma Julia Wagner, Somerville, Mass.; Tufts College Medical School, Boston, 1905; member of the Massachusetts Medical Society; aged 76; died, June 12, of arteriosclerosis.

Durwood Leigh Dodd, Aspermont, Texas; Baylor University College of Medicine, Dallas, 1922; formerly health officer of Austin; aged 41; was shot and killed, June 30.

Charles Thomas Price, Point, Texas; Gate City Medical College, Dallas, Texas, 1906; St. Louis College of Physicians and Surgeons, 1912; aged 67; died, June 30, of pneumonia.

Clement E. Ryan Ⓢ Appleton, Wis.; Louisville (Ky.) Medical College, 1902; aged 69; on the staff of St. Elizabeth Hospital, where he died, June 3, of coronary occlusion.

John Andrew Meldrum, Guelph, Ont., Canada; University of Toronto Faculty of Medicine, 1883; at one time medical health officer of Weston; aged 81; died, June 24.

Kenneth Brown Rothey, Elizabeth, Pa.; Duke University School of Medicine, Durham, N. C., 1933; aged 30; died, June 17, in St. Francis Hospital, Pittsburgh.

Fairbairn McLennon Liverpool, Raleigh, N. C.; Howard University College of Medicine, Washington, D. C., 1937; aged 35; died, June 4, of pulmonary tuberculosis.

Joseph Francis Foley, Wilton, N. H.; School of Medicine and Surgery of Montreal, Que., Canada, 1904; aged 57; died, June 25, in St. Joseph Hospital, Nashua.

Frank Edwin Snider, Cincinnati; Medical College of Ohio, Cincinnati, 1897; aged 67; died, June 4, of chronic myocarditis, arteriosclerosis and cerebral hemorrhage.

Herbert F. Shaw, Mount Vernon, Maine; College of Physicians and Surgeons, Boston, 1883; aged 83; died, June 19, of chronic myocarditis and arteriosclerosis.

Benjamin Franklin Brubaker, North East, Pa.; Medico-Chirurgical College of Philadelphia, 1893; aged 80; died, June 7, of acute bronchitis and nephritis.

William P. Ross, Madisonville, Ky.; University of Louisville Medical Department, 1885; formerly mayor; aged 75; died, June 8, of carcinoma of the rectum.

Joseph Franklin Gill, Dallas, Texas; Memphis (Tenn.) Hospital Medical College, 1902; formerly member of the state legislature; aged 67; died, June 18.

Isidor Besness Goodman Ⓢ New York; Medico-Chirurgical College of Philadelphia, 1914; on the staff of the Morrisania Hospital; aged 50; died, June 21.

Howard F. Craig, Protection, Kan.; Eclectic Medical University, Kansas City, Mo., 1911; member of the Kansas Medical Society; aged 55; died, June 11.

Adolph Bernard Lindquest Ⓢ Omaha; Omaha Medical College, 1901; served during the World War; aged 64; died, June 4, of coronary thrombosis.

Henry Clinton Stream, Des Moines, Iowa; Kentucky School of Medicine, Louisville, 1897; aged 64; died, June 23, of carcinoma of the esophagus.

David Kenneth Fenwick Mundell, Niagara Falls, Ont., Canada; Queen's University Faculty of Medicine, Kingston, 1916; aged 48; died, June 14.

Robert Herman Rowe, Abingdon, Va.; University of Louisville (Ky.) Medical Department, 1912; aged 51; died, June 14, of angina pectoris.

Jacob Hoover Deardorff, Mechanicsburg, Pa.; Hahnemann Medical College of Philadelphia, 1876; formerly county coroner; aged 93; died, June 29.

Enoch C. Haile, Rogersville, Mo.; University Medical College of Kansas City, Mo., 1907; aged 54; died, June 9, of accidental gunshot wounds.

George C. Taylor, Pasadena, Calif.; University of Louisville (Ky.) Medical Department, 1875; aged 87; died, June 10, of cerebral hemorrhage.

Guy Daniel Tibbetts Ⓢ Antrim, N. H.; Tufts College Medical School, Boston, 1911; served during the World War; aged 51; died, June 2.

Thomas H. Wilkins, Portsmouth, Va.; University College of Medicine, Richmond, 1900; aged 61; died, June 29, of carcinoma of the pancreas.

Felix G. Smith, Bethany, Mo.; Ensworth Medical College, St. Joseph, 1888; aged 90; died, June 23, in Cherryvale, Kan., of chronic myocarditis.

De Witt Clinton Buck, Eldorado, Okla.; University of Louisville (Ky.) Medical Department, 1893; aged 70; died, July 5, of myocarditis.

Johanna Mena Droppers, Milwaukee; Northwestern University Woman's Medical School, Chicago, 1893; aged 75; died, June 12, of influenza.

Byron L. Perlee, Uehling, Neb.; Omaha Medical College, 1901; aged 78; died, June 2, of carcinoma of the upper part of the abdomen.

Cass A. Bennett, Withamsville, Ohio; Medical College of Ohio, Cincinnati, 1878; aged 91; died, July 8, in a hospital at Middletown.

John David Moulder, Lebanon, Mo.; University Medical College of Kansas City, Mo., 1901; aged 58; died, June 1, of gastro-enteritis.

William H. McDonald, Newsome, Texas; Missouri Medical College, St. Louis, 1899; aged 64; died, June 5, of uremia and pneumonia.

Paul E. Outerbridge, New York; University of Vermont College of Medicine, Burlington, 1884; aged 79; died, June 16, of pneumonia.

Oscar Fleich, Brooklyn; Baltimore Medical College, 1897; member of the Medical Society of the State of New York; died, June 4.

Lee McAdams, Gibsonia, Pa.; Kentucky School of Medicine, Louisville, 1881; aged 88; died, June 9, of cerebral hemorrhage.

Robert Eugene Wilson, Cartersville, Ga.; Atlanta School of Medicine, 1906; aged 72; died, June 2, of cardiovascular renal disease.

Edward Kisel Ⓢ Ambridge, Pa.; University of Pittsburgh School of Medicine, 1927; aged 36; died, June 4, of coronary occlusion.

Charles Merrill Rose Ⓢ Los Angeles; Syracuse University College of Medicine, 1909; aged 54; died, June 9, of arteriosclerosis.

Enos P. McCormick, Artesia, N. M.; Hospital College of Medicine, Louisville, Ky., 1889; aged 75; died, June 12, of pellagra.

John Stuart Timpany, Digby, N. S., Canada; Detroit College of Medicine, 1893; aged 70; died, June 15, of heart disease.

Lucian E. Maples, Morgan, Texas; Louisville (Ky.) Medical College, 1890; aged 78; died, June 5, of coronary occlusion.

Adam George White Ⓢ Lynchburg, Va.; College of Physicians and Surgeons of Chicago, 1890; aged 81; died, June 3.

Bennett Graff, Tulsa, Okla.; Western Pennsylvania Medical College, Pittsburgh, 1901; aged 72; died, June 29.

Bureau of Investigation

TWO FOREIGN MAIL-ORDER FRAUDS

A "Bust Developer" from Paris

For a good many years "Madame Helene Duroy" has advertised an "Exuber Bust Developer" and an "Exuber Bust Raffermer," the last named to strengthen the bust and make it firm. But the astute Helene played both ends of the game and to those who thought they needed it she also sold a treatment for reducing the bust.

In some of her circulars sent out in recent years she modestly styled herself a "celebrated Parisian specialist" and confided:

"My own coquetry induced me to study this double problem: a good medical education and a sound knowledge of physiology have shown me the way. Long efforts and researches have brought me success

"Only when, after a short period of treatment, you will have admired in the mirror your bust as it becomes rounder and firmer, only when envy and chagrin will have disappeared, when you see your beautiful bust so much admired, then you will understand the influence that harmonious curves exert on your environment, and you will be glad to have consulted me. . . . I not only specialize in the treatment of beauty, but I am also your counsellor and friend."

The Post Office Department twice found it necessary to debar "Mme. Duroy's" products from the United States mails by means of fraud orders. The first of these was issued July 29, 1937, and covered both the "Developer" and the "Raffermer." It was then brought out that not only were these devices worthless for the purposes for which they were sold but that they might injure the delicate tissues of the breasts, with serious subsequent possibilities.

In December 1938 the Post Office learned that Helene Duroy was evading the fraud order by using the name M. G. Duhamel. It was found that she had solicited prospective customers in this country by means of a circular in lame English reading as follows:

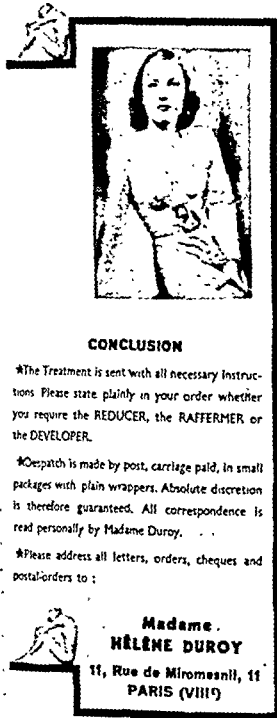

"Owing to the big success my methods are obtaining in U. S. A., I just created a special Department for my American Clients and beg you to send your enquiries, orders and payments only to the following address: Shipping Dept. M. G. Duhamel, 15 rue de Teheran, PARIS 8 (FRANCE).

"As to your information I beg to add that the most simply and quickest way to forward the remittance would be to send the amount in bank-notes (or cheque) by REGISTERED mail. I would highly advise this kind of remittance as the usually in U. S. A. employed Money Orders take sometimes many weeks before coming to hand in Paris.

"Will you please follow strictly these recommendations as all enquiries, correspondences and ORDERS FROM U. S. A. CAN ONLY BE EXECUTED by my new American Department, viz:

"M. G. DUHAMEL, 15 RUE DE TEHERAN, PARIS 8eme. (FRANCE)."

Hon. W. E. Kelly, Acting Solicitor for the Post Office, naturally decreed that "this is a scheme for obtaining money through the United States mails by means of false and fraudulent pretences, representations and promises and is an evasion of the fraud order of July 29, 1937," and a new fraud order was issued Dec. 14, 1938, to cover the name of M. G. Duhamel of Paris.

CONCLUSION

*The Treatment is sent with all necessary instructions. Please state plainly in your order whether you require the REDUCER, the RAFFERMER or the DEVELOPER.

*Despatch is made by post, carriage paid, in small packages with plain wrappers. Absolute discretion is therefore guaranteed. All correspondence is read personally by Madame Duroy.

*Please address all letters, orders, cheques and postal-orders to:

**Madame
HELENE DUROY**
11, Rue de Miromesnil, 11
PARIS (VIII)

Part of the Duroy advertising.

A Contraceptive from Berlin

From Berlin, Germany, an individual advertising as Dr. Richard Weiss has for some years been putting out various nostrums for tuberculosis, obesity, diabetes, gout, asthma, catarrh, vaginal infections, urethritis and some other things. His "Pancreasal Tablets" for diabetes was declared by the Council on Pharmacy and Chemistry to be unacceptable for New and Nonofficial Remedies in THE JOURNAL, March 27, 1933.

Chiefly, Weiss seems to have played up certain products for sexual weakness and presenility in both sexes. Finally, his advertising of "Amural" for contraceptive use came to the attention of the Post Office Department because the importation of such contraceptive matter is forbidden by statute and its seizure and destruction are authorized at points of entry. Hence, persons remitting money to the promoters of this business would receive nothing in return.

In his memorandum recommending the issuance of a fraud order against the Weiss scheme, Hon. W. E. Kelly, Acting Solicitor for the Post Office Department, pointed out that it is practically impossible to treat effectively by mail patients who suffer from any of the various disorders for which the Weiss nostrums are advertised, and the patients relying on the preparations in question would only grow worse, chiefly through neglect to obtain scientific treatment for their troubles.

Mr. Kelly brought out also that one of Weiss's treatments was for "lost manhood" and he presented scientific evidence that no combination of vitamins or hormones would constitute a proper and effective treatment for all of the many causative factors involved in the condition named. He therefore found the representations for this and other Weiss products to be false and recommended the issuance of a fraud order. It was issued on Oct. 3, 1938.

VARIOUS "SEX" FRAUDS

During 1938 the Post Office Department closed the mails to various frauds of the sexual type. These frauds make their appeal to a class of individuals lacking in ordinary intelligence. Some of them, such as the mechanical-masturbator type of fraud, appeal only to the feeble-minded or at least completely unintelligent individuals, while others, including impotence "cures," have a wider, but only slightly higher class, clientele.

For these reasons the Bureau of Investigation is publishing only the briefest outline of Post Office fraud orders of this type which have appeared in the last year or so.

These are named in the following list with the number designation of the fraud order, the date of issuance, the name of the product and its promoters, with its description, and a list of ingredients, if known:

No. 11539, April 5, 1938, "V. V. V."; Eclipse Specialties Co., Glen Rock, N. J.; male sex organ "developer"; cottonseed oil with minute amount of volatile aromatic oil added. A supplemental fraud order (No. 12063) was issued on Aug. 31, 1938, to cover the new names adopted by the same concern, "Honest Home Products Co." and "Eureka Lubricating Cream."

No. 12356, Dec. 8, 1938, "Jay's Kapsuls"; Jay Medicine Co., Brooklyn; "sex rejuvenator"; yohimbine hydrochloride, mutrapuama and nux vomica extract, with various glandular substances.

No. 12359, Dec. 8, 1938, "Vita-Mon"; Marine Products Co., Los Angeles; "sex rejuvenator," and the like; tablets containing iodine, calcium and magnesium compounds, and starchy materials.

No. 12360, Dec. 8, 1938, "Juvenator"; Barton Sales Agency, Chicago; mechanical masturbator.

Fit to Train Practitioners.—The man who is fit to train the practitioner to begin his lifework must be thoroughly familiar with everything that makes for successful practice, must not only understand disease and its management in its detail, but must be familiar with the science, skilful and precise in the craft, and versatile and diplomatic in the art. But these varied accomplishments will not fit him for the professional chair.—Lewis, Sir Thomas: Research in Medicine and Other Addresses, London, H. K. Lewis & Co., Ltd., 1939.

CHANGE IN MEDIUM FOR SCARLET FEVER TOXIN

To the Editor:—Some persons who have received injections of diphtheria toxoid, especially the alum precipitated toxoid, may be sensitized to proteins contained in veal broth and consequently develop urticaria following injection of other veal broth preparations.

To avoid the development of urticaria in such persons during the course of immunization against scarlet fever, the medium in which scarlet fever toxin is produced has been changed to one which contains no meat infusion. Use of this medium results in a toxin containing considerably less protein and a marked reduction in the incidence of urticaria.

GLADYS H. DICK, M.D., Chicago.

THE ELECTRIC BONE SAW

To the Editor:—A few months ago one of the popular monthly magazines carried an article telling about recent inventions that had been of benefit to humanity and referred to the electric saw as an instrument of present day development.

While there have been some modifications in design by different men during the past thirty years, the electric osteotome was invented and in use in the eighties.

The following description of an electric bone cutter is taken from the *Provincial Medical Journal* of 1889 and is a quotation from the *Electrical Engineer* (London) of Aug. 3, 1888:

Removal of sections of bone in surgical operations has heretofore been a long, tedious process, effected with a mallet, chisel, gouges, etc. It is, perhaps, the most brutal and unscientific method which could be adopted, and sounds like the operative butchery which existed in the last century. According to the *Electrical Engineer*, August 3rd, 1888, this has all been reformed by an invention called the electric osteotome, which is an instrument holding a circular saw at its extremity, revolved with lightning speed by an electric motor. This, when held against a bone, makes a clean cut through it in a few seconds; in fact, its action is instantaneous. By holding the osteotome in a slanting position, wedge-shaped pieces can be cut out with equal promptitude. There is no danger of the saw cutting the soft parts, as they are protected by a retractor, an instrument which is passed down and under the bone.

The illustration accompanying the article in the *Provincial Medical Journal* showed a small circular saw on a shaft about 6 inches long, in direct line with the small motor.

D. C. PATTERSON, M.D., Bridgeport, Conn.

"THE CHALLENGE OF APPENDICITIS"

To the Editor:—In your editorial "The Challenge of Appendicitis" (THE JOURNAL, May 20), education of the public is stressed as one of the means by which the mortality of acute appendicitis might be reduced. "Education of the public about appendicitis applies to the most important two factors responsible for the increasing mortality, i. e. the increasing use of cathartics for abdominal pain and the delay in the diagnosis and treatment."

Efforts in this direction have been made over a considerable period of time, yet how common it is to find that they have failed of their purpose of warning the patient who falls ill of acute appendicitis. One serious misconception regarding the pain of appendicitis is remarkably prevalent among the public, namely that it is "a pain in the right side." Strangely, the press and the other avenues of public information have never stressed the fact that the pain of acute appendicitis is in the middle of the abdomen. This location of the first (and therefore the therapeutically important) pain is so constant that despite the few exceptions, a pain developing first in any lateral part of the abdomen counts against the diagnosis of acute appendicitis.

How frequently the history includes such statements as "Right away I thought of appendicitis but the pain wasn't on my right side so I knew it couldn't be that"; "I made sure he didn't have any pain on the right side before I gave him the magnesia." Statements such as these are made by persons in all walks of life, including intelligent and well educated individuals. Let any select group, for example engineers, school teachers, business executives or even members of physicians' families, be asked "How would you know if you were stricken with acute appendicitis?" There is great likelihood that the most favored answer would be "I would have a pain in the right side." This simple question merits trial on radio quiz programs.

In contrast to the general complacency toward pain in the middle of the abdomen, so often a symptom of grave import, is the serious concern excited by any right-sided pain. What physician has not had occasion to calm a panicky patient who is terrified with the conviction that he has acute appendicitis and faces operation because he has a pain on the right side of the abdomen, when as a matter of fact the pain is due to some relatively trifling condition readily relieved by simple measures? This common experience is further proof of the firmly fixed popular mistake regarding the predominant symptom of acute appendicitis.

Cases in which life has been needlessly jeopardized as a result of this misconception have often prompted me to state "It should be printed in every newspaper in the United States that the pain in acute appendicitis is in the middle of the abdomen." Such publication, together with widespread dissemination of the same fact by every other possible means, should be confidently expected to effect a greater reduction in the mortality of acute appendicitis than any other single new measure now available.

JOSEPH NASH, M.D., New York.

"PSYCHOSOMATIC MEDICINE"

To the Editor:—If the editorial on psychosomatic medicine (THE JOURNAL, August 5) is indicative of what is to be expected of the journal with that name, the periodical will offer little by way of elucidating the problems involved in correlating the psychic with the physical. This arises out of an incomprehension of the problem at issue and the purpose of restricting the manner by which this correlation is to be effected to the "scientific method." It intends to ignore or disregard the "metaphysical approach." If this is so, then the *Journal of Psychoanalysis* already meets its needs.

Too often concepts are "new" because their authors have not adequately exercised the faculties of retrospection or critical observation. Nor have they perused sufficiently broadly the wealth of learning that is piled on library shelves. "Psychosomatic" indicates mind-body with the implied distinction of "mind" as something other than "body" which is all that is implied by the prefix "meta." Consequently there is no need for newness. It only engenders greater confusion by reason of the arbitrary meaning that must be ascribed to it apart from the connotation it will continue to bear by reason of its association with other words whose meaning is quite clear. There is reason to fear that this revulsion against the old terminology is an expression of escape from all that it connotes. No physician divorced from the paraphernalia of the laboratory or office will deny that there is something involved in human illness which is beyond the physical to explain, which is not mensurable by physical instruments and which is therefore not to be encompassed by the "scientific method."

Far from there being a need of additional journals bearing new titles for older and more comprehensive ideas, there is an imperative need for a reduction in their number. Analytic science has so fragmented the physical aspects of medicine that it is almost impossible to reconstruct an intelligible design from them. Through psychoanalysis not only has this been

attempted with the mind but it has also attempted the translation of psychic or metaphysical activity into physical phenomena. Psychic or mental activity is nonphysical and therefore spiritual. There is no consideration of the spiritual respecting man that does not involve the inclusion of morals or ethics. That is conduct. Whatever need there may be for a journal devoted to correlating metaphysical or psychic activity with biologic phenomena, its purpose would be encompassed by what is understood as pastoral medicine.

JOHN F. QUINLAN, M.D., San Francisco.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

THE VASOMOTOR MECHANISM

To the Editor:—In two articles (Myerson, Abraham: Human Autonomic Pharmacology, *The Journal*, Jan. 8, 1938, p. 101. McNally, W. J.; Stuart, E. A.; Reid, T. F., and McConnell, L. H.: An Experimental Investigation of Tinnitus, *J. Laryng. & Otol.* 51: 363 [June] 1936) there has been a tabulation of drugs affecting the vasomotor mechanism. Will you kindly tabulate all the well known drugs including the newer ones that have been shown to cause vasoconstriction and vasodilatation? That is, those drugs which stimulate and depress the sympathetics and also those which stimulate and depress the parasympathetics. Is ergotamine rightly classified as a depressor of the sympathetics. I have been especially interested in this study from the effect on raising or lowering the blood pressure. What is the mechanism of the action of amyl nitrite, phenobarbital, theophylline with ethylenediamine (aminophyllin) and theobromine on blood pressure?

Willard F. Goff, M.D., Washington.

ANSWER.—The caliber of the blood vessels is passively affected by shifts in the distribution of blood and actively controlled by the contractile tissues of the vessel walls. Direct effects on the contractile mechanisms result from chemical agents: metabolic, endocrine and pharmacologic. Mediated effects involve the (autonomic) nervous system. Although the primary object of the blood flow is to provide for local tissue needs, the regional distribution is determined by the capacity of the body to meet and coordinate all circulatory requirements. The nervous and endocrine regulators of the anatomic units operate under guidance of the controlling mechanisms of the central nervous system. It is not practicable, therefore, to classify, say, a vasoconstrictor drug such as epinephrine without specifying on which vessels and under what circumstances it acts. Typically, this drug causes vasoconstriction by stimulating those elements in the contractile mechanism of the vascular bed which normally respond to nervous impulses, reaching them by way of the thoracolumbar sympathetic system. There are, however, some sympathetic vasodilator fibers whose effects may preponderate, both in particular vessels such as the coronary arteries and in sites such as the kidney, which are normally vasopressor but which show the well known "reversal" after paralyzing doses of ergotoxin. The general rise in blood pressure after an injection of epinephrine is accompanied by a redistribution of the blood, which passively dilates many vessels (especially in the heart, brain and lungs) that have little, if any, vasoconstrictor innervation. The cardiac effects of epinephrine are typically accelerator and augmentor and contribute to the rise in blood pressure and alterations of the distribution of the blood. Frequently there is a (vagal) cardiac slowing during the hypertensive period. This is due to aortic and carotid sinus stimulation of "pressoreceptive" mechanisms (Heymans, C.: *New England J. Med.* 219:147 [Aug. 4] 1938) and the associated controlling reflexes. Sometimes cardiac irregularity ensues and may greatly modify the general and regional picture. The action of the drug may be changed considerably if several drugs are acting simultaneously. It is also often a question of the particular physiologic balance, that is heart rate and blood pressure level, obtaining at the time of administration. An adequate classification should take all these points into consideration.

The active vasodilator mechanisms are partly direct and partly mediated by vasodilator nerves. The anatomy of the latter is ill understood. The minority are parasympathetic in origin. Many run in the true sympathetic. Others, usually described as

"antidromic" vasodilators, are associated with somatic afferent nerves; they are the type usually involved in axon reflexes and the action of counterirritant drugs. Nerve-controlled vascular changes in the cutaneous areas are important in the regulation of heat loss, which assists in the control of the body temperature. Passive vasodilatation is secondary to general and remote circulatory changes.

The older terms sympathomimetic and parasympathomimetic as a basis for classification of autonomic drugs are falling into disuse. This is largely because of the recognition of at least four levels at which the autonomic nervous system is subject to pharmacologic action. Traced from the effector organ, these are (1) terminal, at the neuro-effector junction, (2) internuncial, especially at the outlying ganglions, (3) central, in the controlling "centers" of the central nervous system, (4) reflex, by way of afferent systems, including the specialized "pressoreceptive" (e. g. carotid sinus) and similar mechanisms.

The terms adrenergic and cholinergic (Dale, Henry: *Harvey Lectures*, 1936-1937, p. 229) are based on the modern view that the transmission of autonomic nerve impulses is mediated by (1) epinephrine-like substances ("sympathins") (Rosenbluth, Arturo: *Physiol. Rev.* 17:514 [Oct.] 1937) in the terminal sympathetic, and (2) acetylcholine-like intermediaries (Loewi, Otto: *Harvey Lectures*, 1932-1933, p. 218) not only in the terminal parasympathetic (muscarine-like action) but also in the ganglionic transmission (nicotine-like action) of both sympathetic and parasympathetic. A large number of drugs acting at the four functional levels of the autonomic nervous system are reviewed by D. E. Jackson (*THE JOURNAL*, Feb. 1, 1936, p. 357). A detailed review of parasympathomimetic drugs is given by V. E. Henderson and M. H. Roepke (*Physiol. Rev.* 17:373 [July] 1937). The literature on the sympathomimetic drugs is scattered.

An attempt to classify vasoconstrictor and vasodilator drugs may be made in tabular form under the following heads: I, stimulant (+) or depressant (—); II, active (A) or passive (P); III, direct (D) or mediate (M), the latter at the four levels (1) terminal, (2) ganglionic, (3) central, (4) afferent (reflex); IV, adrenergic (A) or cholinergic (C), whether "muscarine-like" (C₁) or "nicotine-like" (C₂); V, sympathomimetic (S) or parasympathomimetic (P); VI, regional peculiarities, with regard to active vasoconstriction (C), vasodilatation (D) or relative inactivity (I). A number of examples may be cited:

A. VASOCONSTRICTOR DRUGS

Epinephrine: I +; II A; III M₁, ?₂ (?D); IV A; V S; VI C—mucosae, skin, splanchnic area; D—coronaries, ?muscles; I—brain, lungs.

Similar (not fully studied): *Nephrine*.

Tyramine: I +; II A; III M₁ (?D); IV A; V S; VI C—usual.

Ephedrine: I +; II A; III D (?M); IV ?A; V ?S; VI C—usual; effective orally.

Similar (pharmacologically): *Neosynephrine*; *Amphetamine*; *Propadrine*.

Ergot (ergotoxine; ergotamine; ergonovine): I ±; II A; III M₁ (?D); IV A±; V S±; VI C—usual; secondary sympatheticallycolytic (epinephrine-reversal) action slight with ergonovine.

Cocaine (not procaine): I +; II A; III M_{1,2}; IV A; V S; VI C—important in local anesthesia.

Nicotine (tobacco smoking): I ±; II A; III M_{2,3}; IV C±; V S, P; VI C—tends to preponderate but effects vary according to (a) site of action, (b) sympathetic vs. parasympathetic antagonism, (c) whether stimulating or paralyzing dose.

Similar: *Lobeline*: central actions predominate, hence uncertainty as to resultant effect on circulation.

Pituitary Gland (pitressin): I +; II A; III D; IV 0; V 0; VI C—capillaries as well as arterioles, including coronaries.

Digitalis: Therapeutically, circulatory changes are secondary to cardiac effects; experimentally, direct vasoconstrictor effects are demonstrable.

B. VASODILATOR DRUGS

"*Nitrites*" (sodium nitrite; amyl nitrite; spirit of ethyl nitrite; glyceryl trinitrate; erythrol tetranitrate; mannitol hexanitrate): I —; II A; III D; IV 0; V 0; VI D—most vessels, including coronaries, ?excluding pulmonaries.

Histamine: I ±; II A (capillaries); P (arteries); III D; IV 0; V 0; VI D—capillaries, overshadows C—arteries.

"*Cholines*" (acetylcholine; mecholyl and the like): I ±; II A; III M_{1,2}; IV C₂; V P; VI D—if cholinergic.

Physostigmine, *Prostigmine*, *Pilocarpine*: stimulate parasympathomimetic vasodilators terminally and cause circulatory shifts through their vagal action on the heart. *Atropine* antagonizes terminally.

"Methyl Xanthines" (caffeine; theobromine; theophylline; aminophylline): I — (?+); II A; III D (?M₂); IV 0; V 0; VI D—direct vasodilator action (including coronaries), aided by cardiac stimulation, usually overcomes central vasomotor stimulation.

Alcohol and Volatile Anesthetics: Peripheral vasodilation in cutaneous areas is largely direct; vasomotor center is first stimulated (hence splanchnic vasoconstriction), later depressed; cardiac effects share in the blood shifts and blood pressure changes.

Soporifics (including *Barbiturates*): similar, but larger doses required; some idiosyncrasy of cutaneous vessels in certain individuals.

Blood Pressure: Vascular changes, if sufficiently widespread, modify the blood pressure by determining the peripheral resistance to the blood flow. These changes, however, must be evaluated in relation to (1) the pumping action of the heart, (2) the "effective" volume and physical characters (e. g. viscosity) of the blood, and (3) factors affecting the elasticity of the vessel walls.

MOLES AND THEIR EXCISION

To the Editor:—Six months ago a patient noticed a slight inflammation in a mole located on his left shoulder. He came to me at once and I excised the mole down to the fascia, using local anesthesia and a scalpel. The sutured wound broke open after several days and healing took place by second intention. Silver nitrate was applied several times to exuberant granulations. The specimen was sectioned by a competent pathologist, who pronounced it an entirely benign mole. All went well then until about two weeks ago, when the patient chanced to read something on malignant melanoma. He at once became a cancerphobe and feeds his fear by reading everything he can find on melanomas. He now complains of vague pains in the left side of the chest and the axilla. Physical examination and roentgenogram of the chest are negative. What can I tell this man? He quotes me textbooks: "Moles in this region (the shoulder) if incompletely removed, especially by cautery, are prone to recur in a malignant fashion" and "Metastases may show up as late as three years after removal of the primary growth." Finally, "Local recurrence is unusual, tumor cells spreading from the local lymphatics into the systemic stream." He gives himself up to three years to live and has even made his will. This outlook is ruining his life. What are the actual statistics, if any, on malignant changes in partially excised benign moles? Should moles be excised at all and, if so, how? Finally, is there any specific test for the presence of melanotic metastases in the body?

M.D., Minnesota.

ANSWER.—The fundamental question in this case is the precise nature of the mole that was removed. If microscopic study of the mole by competent pathologists resulted in the diagnosis of a benign lesion and there is neither clinical evidence of local recurrence nor distant metastases, one can assure the patient that his disease is cured and that he has no melanoma.

When a benign mole is excised completely, the question of melanoma does not arise. The best procedure to adopt regarding treatment of moles is to perform careful and complete excision of moles which are so placed as to be subject to irritation and also moles which are showing certain changes, especially growth or increase in pigmentation. There is no specific test for the presence of metastatic foci of melanoma in the body.

LEVULOSURIA

To the Editor:—Is levulosuria treated the same way as ordinary diabetes mellitus? Is it influenced by insulin and does it require a particular diet? My patient is a woman of 21 who eliminates about 12 Gm. of levulose in twenty-four hours.

Judah Minkin, M.D., Bronx, New York.

ANSWER.—In the case mentioned, one assumes that the diagnosis of levulosuria has been definitely established. This is done by demonstrating in the urine the presence of sugar which reduces alkaline copper solutions, is fermentable, gives a positive Selivanoff's test and, with methylphenylhydrazine, yields osazone crystals with a characteristic microscopic appearance and melting point. To prove the absence of diabetes, a formal dextrose tolerance test should be carried out.

Levulose, like pentose, reduces Benedict's solution within ten minutes at temperatures of from 50 to 60 C., although not quite as rapidly or at quite as low a temperature as does pentose.

In contrast to diabetes mellitus, levulosuria is a harmless condition. There is no need for dietary restriction, insulin or other treatment except reassurance.

Levulosuria represents an error of metabolism, probably inborn, in which the rate of removal of levulose from the blood stream is retarded, presumably because of hepatic dysfunction. As judged by other tests, however, the liver function in reported cases has been normal.

LIVE RED ANTS AND ARTHRITIS

To the Editor:—I am enclosing a folder entitled "The Medicinal Value of the Live Red Ant," presented as an address by Dr. William P. Mowry. This was brought to me by a patient with chronic arthritis. Will you please comment on this treatment. E. T. Morris, M.D., Nashville, Mich.

ANSWER.—The enclosure was titled "Reprint of Address Delivered to the Batavia Grange No. 95, January 1, 1938, by William P. Mowry, M.D., on The Medicinal Value of the Live Red Ant." The reprint is not from a medical journal but is in reality an advertisement. Therein was mentioned the supposed value of "Rufa, the new scientific treatment for rheumatism, arthritis and kindred diseases, the principal ingredient of which is the secretion of the live red ant." Having himself had "arthritis" for several years, which was unrelieved by other measures, Dr. Mowry claims that he "got relief within five hours from the first treatment and never took over five doses." Three other patients then tried the remedy with results which were "astounding" and "miraculous." Presumably similar results were later noted in "case after case." The proponent of this remedy believes that arthritis is due to intestinal toxins, intestinal stasis and impure blood. "Therefore to get results we must change the consistency of the blood stream and at the same time inhibit the growth of bacteria." One is allowed to believe that "Rufa" does just that.

It seems hardly necessary to comment on this. The "remedy" appears to be just one more rheumatism "cure." No shred of scientific evidence is offered to support the claims made. Nothing on the subject has appeared in medical literature. Rheumatism remedies of the past have included horse chestnuts, snake oil, animals' urine and other excreta, and bee venom. To this group can now be added the secretion of the live red ant. There can be no great objection to a trial, on empirical grounds, of such substances. Animal extracts of all sorts have had a perennial fascination for human beings seeking cures. But before such extracts are exploited as effective they must be subjected to the ordinary rules of scientific evidence. Most forms of chronic rheumatism are notoriously variable in their course; they are characterized by frequent remissions and exacerbations and eventually they usually stop spontaneously. The reason so many nostrums can gain a reputation for efficacy is, of course, that they have a psychic effect or that they are used during a natural remission of the disease.

PRESENILE PSYCHOSIS

To the Editor:—Has there been any recent work or publication on vitamin B₁ therapy in presenile psychosis? Since the early symptoms of a presenile psychosis, namely the retrograde amnesia, are also a dominant early feature of pellagra psychosis is it not possible that the former may be related to a condition of avitaminosis? Any references or information extended will be greatly appreciated. What is the nature of the psychosis that may accompany Addison's disease?

M.D., Illinois.

ANSWER.—There has been no recent publication on vitamin B₁ therapy in presenile psychosis (Alzheimer's disease). The following are some recent references on the clinical and physiologic effects of vitamin B₁ deficiency in man:

- Peters, R. A.: Physiology and Biochemistry of Vitamin B₁, *Tr. Roy. Soc. Trop. Med. & Hyg.* 31: 483-492 (March) 1938.
- Schretzenmayr, A.: Clinical Aspects of B₁ Avitaminosis, *Klin. Wchschr.* 16: 1737 (Dec. 11) 1937.
- Goodhart, Robert, and Jolliffe, Norman: Effects of Vitamin B₁ Therapy on Polyneuritis of Alcohol Addicts, *THE JOURNAL*, Feb. 5, 1938, p. 414.
- Cowgill, G. R.: Human Requirements of Vitamin B₁, *ibid.*, Sept. 10, 1938, p. 1009.
- Steven, H.: Avitaminosis B₁, Maze Performance and Certain Aspects of Brain Chemistry, *J. Comp. Psychol.* 24: 441-458 (Dec.) 1937.
- Wortis, S. B.: Metabolism of Brain Tissue: Enzymes and Vitamins in Brain, *Bull. Neurol. Inst. New York* 4: 588-596 (April) 1936.

Presenile psychosis (Alzheimer's disease) is a progressive cerebral degeneration with the pathologic picture of senility occurring in middle life. The essential neuropathologic lesion is a diffuse degeneration of the cerebral cortex involving all the layers but most marked in the frontal lobes. There is degeneration of the ganglion cells of the cortex, and often one finds a profusion of senile plaques throughout the cortex. The illness develops between the ages of 35 and 55 and the symptoms are essentially those of a progressive dementia with speech disturbance and apraxia. The onset is insidious, and subsequently the patient suffers from loss of memory, habit deterioration, epileptiform seizures, slurring of speech and finally complete disorientation.

Pellagra is characterized by a combination of cutaneous, digestive, nervous and mental symptoms. Neuropathologic studies

show thickening of the meninges, and the brain may be atrophic or edematous. Chromatolysis and pigmentation are found in the ganglion cells of the brain and in the autonomic ganglions. The spinal cord often shows degeneration of the posterior columns. Outside the nervous system one finds cutaneous erythema and atrophic changes in the stomach and intestine. Pellagra usually starts with gastrointestinal symptoms (aggravating the avitaminosis) associated with cutaneous lesions. Nervous and mental changes develop later and are usually in the nature of a depressive state, a delirium or an "organic reaction" with loss of memory, disorientation, confusion and finally dementia.

The presenile psychosis develops in persons who are receiving adequate food and vitamin intake.

The mental symptoms accompanying Addison's disease (adrenal disease) are fatigability, asthenia, headache, insomnia, vertigo, tinnitus, syncope, depression and irritability. In later stages, when the physiologic disturbances are severe, one finds delirium, convulsions, stupor and coma. This condition is best treated by substitution therapy with cortical extract and sodium therapy to replace the loss of sodium from the body.

INTERMITTENT WATERY DISCHARGE FROM UTERUS

To the Editor:—Kindly advise me as to treatment in a case of copious watery discharge from the uterus. The woman, aged 37, is in perfect health otherwise. She was operated on for chronic appendicitis ten years ago. The surgeon told her after the operation that the tubes had been taken out and that she never would be able to have a baby. She actually never has been pregnant. The discharge started a year and a half ago and is growing worse. It is a clear, watery, slightly mucous discharge coming intermittently in big gushes, so that her underwear and bedding are actually wet. The origin of the discharge is the uterus; there is no urinary fistula. The menstruation is normal; bimanual examination is negative and the cervix is normal. An experienced gynecologist examined the patient. He is thinking of an intermittent hydrosalpinx (which he himself has never seen) but apparently the tubes have been taken out! He has also thought of a carcinoma of the tube, but the discharge never has been blood tinged. Thus he also cannot account for the unusual condition.

M.D., New York.

ANSWER:—Since bimanual examination has failed to reveal any abnormality, it is advisable to resort to hysterosalpingography. The injection of iodized oil into the uterine cavity will not only reveal the size and shape of the uterine cavity but, if one or both tubes or only parts of them are present and they are patent, will also demonstrate their lumens. Of course, if the tubes are present but closed at the uterine end there will be no evidence of this in the hysterosalpingogram.

If the injection of iodized oil fails to give any information, a dilation and curettement may be performed. If there is a stricture of the cervix, the dilation will overcome it, as may also the dilation of the cervix at the time of the hysterosalpingogram. A stricture of the cervix may be responsible for the intermittent watery discharge, especially if there is a small fibroid in the cervix which acts as a ball valve.

A curettement will reveal whether or not a carcinoma of the corpus is present, because this condition often is the cause of a watery discharge. However, after a year and a half the discharge from cancer would almost certainly be bloody and the patient would not be in good health.

Furthermore, a curettement will demonstrate the possible presence of tuberculosis of the endometrium. No mention is made of the reason for the bilateral salpingectomy, but the patient may have had tuberculous salpingitis. Even if no gross abnormality is revealed by the curettage, this operation might produce a cessation of the discharge. If the hysterosalpingogram and the curettement fail to bring about a cure, an exploratory laparotomy with a hysterectomy may be necessary.

DIATHERMY AND CATARACTS

To the Editor:—A man aged 62 has incipient cataracts. He has purchased a General Electric short wave diathermy apparatus, which he uses for treatment of his sinuses with considerable symptomatic relief. He has asked me whether treatment to the nasal areas will tend to increase the cataract formation. As I have no reference on this, I would appreciate your opinion.

M.D., New York.

ANSWER:—As far as is known, the use of short wave diathermy about the head has no influence on the development or progress of opacities of the lens. It is perfectly conceivable that excessive heating of the ocular structures, particularly by deep penetrating heat, could hasten opacification of the lens, but the patient would protest violently against the amount of heat because of the superficial tissue discomfort.

POSITIVE WASSERMANN REACTION IN MAID

To the Editor:—A Negro maid working for a patient of mine submitted to a routine serologic examination. The result was a 4 plus Wassermann reaction (titer 10 plus). She refused to give a history and also refused to submit to a physical examination. She denied knowing of any date of origin (this condition is not hereditary, since the reaction in her family is negative) but admits many sexual contacts. There has been no treatment. I advised the patients to rid themselves of the maid (there is one child in the home) at least until she has received a minimum of treatment. Here is the situation: Several reputable physicians have told my patient that she can keep the maid (not having examined the girl) on the ground that, having a positive Wassermann reaction, she is less dangerous than one whose blood reaction is negative. This seemed stupid to me. However, I would appreciate an answer adequately explaining the possible infectiousness of the maid. Repeated serologic tests have given similar results. A prompt reply would be appreciated, as there has arisen quite a controversy over the question. The real question to answer is Can a maid with definite untreated syphilis be permitted to work in a home without any danger to her contacts, no matter how little?

M.D., New York.

ANSWER:—The fact that the patient's Wassermann reaction is positive, that she is in the active years of life and that she does not have hereditary syphilis would make one suspicious that she is probably in the active stage of the disease. That may be one reason why she has refused a general physical examination. Moreover, she admits many sexual contacts. Of course the advice that a maid who has a routine positive serologic blood reaction is less dangerous than one whose blood reaction is negative is nonsense. Certainly a person with untreated syphilis cannot be permitted to work in a home where there is danger of contacts with other members of the family in various ways, particularly with linen and dishes. The physician should insist on a general physical examination at once.

NEOPRONTOSIL AND CARCINOMA

To the Editor:—I have been using neoprontosil extensively since it appeared on the market in tablet form. Some time ago I heard a pathologist mention the fact that the red dye contained in this drug resembled a dye which he had been experimenting with a year or so ago. The research that he conducted was to find out whether the dye would do any harm to the workers handling it. The results of the research showed that the dye produced cancer of the bladder in practically all dogs to which it was given within a period of from three months to one and a half years. I would be interested in knowing whether any experiments have been conducted with the red dye contained in neoprontosil to exclude the possibility of its being carcinogenic.

W. A. H. Scheffler, M.D., Camden, N. J.

ANSWER:—There are no recorded data regarding the possible carcinogenic effects of neoprontosil. However, certain unpublished information indicates that this compound is not carcinogenic in strains of mice which ordinarily are susceptible to chemical agents that produce cancer.

PHOSPHATASE TEST FOR RAW MILK

To the Editor:—It is suspected that bottles of raw milk are being sold in this community as pasteurized milk. Is there any way of determining whether this milk has been pasteurized as labeled? M.D., New York.

ANSWER:—In the laboratories of many large cities a test known as the phosphatase test is used for the purpose of differentiating raw from pasteurized milk. This test is based on the fact that phosphatase, an enzyme, is present in fresh, normal, unpasteurized milk but is completely inactivated by pasteurization.

An article (The Practical Value of the Phosphatase Test in Determining the Efficiency of Pasteurization) by F. W. Gilcreas and W. S. Davis of the New York State Department of Health was published in the thirtieth annual *Proceedings of the International Association of Milk Dealers*, laboratory sections 34-56, 1937.

VARICOSITY ON DORSUM OF PENIS

To the Editor:—A healthy 15 year old boy has a varicose vein on the dorsum of the penis. Is this amenable to injection of a sclerosing solution? If so, please outline the technic and the contraindications, if any. If not, what treatment do you advise? Isadore Shechner, M.D., Newark, N. J.

ANSWER:—A dilated dorsal vein of the penis is not uncommon and need not be treated unless it causes discomfort. Injections are not advisable, as they might produce painful lumps and cause ascending thrombosis. Resection of a small segment with union of the two stumps would produce the most satisfactory collapse and shortening of the varicosity.

Medical Examinations and Licensure

COMING EXAMINATIONS

NATIONAL BOARD OF MEDICAL EXAMINERS SPECIAL BOARDS

Examinations of the National Board of Medical Examiners and Special Boards were published in THE JOURNAL, September 9, page 1056.

STATE AND TERRITORIAL BOARDS

ALABAMA: Montgomery, June 18-20. Sec., Dr. J. N. Baker, 519 Dexter Ave., Montgomery.

ARIZONA: Phoenix, Oct. 3-4. Sec., Dr. J. H. Patterson, 826 Security Bldg., Phoenix.

ARKANSAS: *Basic Science*. Little Rock, Oct. 23. Sec., Mr. Louis E. Gebauer, 701 Main St., Little Rock. *Medical (Regular)*. Little Rock, Nov. 9-10. Sec., Dr. D. L. Owens, Harrison. *Medical (Eclectic)*. Little Rock, Nov. 9-10. Sec., Dr. Clarence H. Young, 1415 Main St., Little Rock.

CALIFORNIA: *Written examination*. Sacramento, Oct. 16-19. *Oral examination* (required when reciprocity application is based on a state certificate or license issued ten or more years before filing application in California). San Francisco, Nov. 15. Sec., Dr. Charles B. Pinkham, 420 State Office Bldg., Sacramento.

COLORADO: *Endorsement*. Denver, Oct. 3. *Examination*. Denver, Oct. 4-6. Sec., Dr. Harvey W. Snyder, 831 Republic Bldg., Denver.

CONNECTICUT: *Basic Science*. New Haven, Oct. 14. *Prerequisite to license examination*. Address State Board of Healing Arts, 1895 Yale Station, New Haven. *Medical (Regular)*. Examination. Hartford, Nov. 14-15. *Endorsement*. Hartford, Nov. 28. Sec., Dr. Thomas P. Murdock, 147 W. Main St., Meriden. *Medical (Homeopathic)*. Derby, Nov. 14-15. Sec., Dr. Joseph H. Evans, 1488 Chapel St., New Haven.

DELAWARE: *Examination*. Dover, July 9-11. *Reciprocity*. Dover, July 16. Sec., Medical Council of Delaware, Dr. Joseph S. McDaniel, 229 S. State St., Dover.

DISTRICT OF COLUMBIA: *Basic Science*. Washington, Oct. 23-24. *Medical*. Washington, Nov. 13-14. *Formal application and supporting data must be received before Oct. 1*. Sec., Commission on Licensure, Dr. George C. Ruhland, 203 District Bldg., Washington.

FLORIDA: Jacksonville, Nov. 13-14. Sec., Dr. William M. Rowlett, Box 786, Tampa.

GEORGIA: Atlanta, Oct. 10-11. Joint-Sec., State Examining Boards, Mr. R. C. Coleman, 111 State Capitol, Atlanta.

HAWAII: Honolulu, Oct. 9-12. Sec., Dr. James A. Morgan, 48 Young Bldg., Honolulu.

IDaho: Boise, Oct. 3-4. Dir., Bureau of Occupational License, Mr. H. B. Whittlesy, State Capitol Bldg., Boise.

ILLINOIS: Chicago, Oct. 17-19. Superintendent of Registration, Department of Registration and Education, Mr. Homer J. Byrd, Springfield.

INDIANA: Indianapolis, June 18-20. Sec., Board of Medical Registration and Examination, Dr. J. W. Bowers, 301 State House, Indianapolis.

IOWA: *Basic Science*. Des Moines, Oct. 10. Dir., Division of Licensure and Registration, Mr. H. W. Grefe, State Department of Health, Capitol Bldg., Des Moines.

KANSAS: Topeka, Dec. 12-13. Sec., Board of Medical Registration and Examination, Dr. J. F. Hassig, 905 N. 7th St., Kansas City.

KENTUCKY: Louisville, Dec. 5-7. Sec., State Board of Health, Dr. A. T. McCormack, 620 S. Third St., Louisville.

MAINE: Portland, Nov. 14-15. Sec., Board of Registration of Medicine, Dr. Adam P. Leighton, 192 State St., Portland.

MARYLAND: *Regular*. Baltimore, Dec. 12-15. Sec., Dr. John T. O'Mara, 1215 Cathedral St., Baltimore. *Homeopathic*. Baltimore, Dec. 12-13. Sec., Dr. John A. Evans, 612 W. 40th St., Baltimore.

MASSACHUSETTS: Boston, Nov. 14-16. Sec., Board of Registration in Medicine, Dr. Stephen Rushmore, 413-F State House, Boston.

MICHIGAN: Lansing, Oct. 11-13. Sec., Board of Registration in Medicine, Dr. J. Earl McIntyre, 100 W. Allegan St., Lansing.

MINNESOTA: *Basic Science*. Minneapolis, Oct. 3-4. Sec., Dr. J. Charnley McKinley, 126 Millard Hall, University of Minnesota, Minneapolis. *Medical*. Minneapolis, Oct. 17-19. Sec., Dr. Julian F. Du Bois, 350 St. Peter St., St. Paul.

MISSISSIPPI: *Reciprocity*. Jackson, December. Asst. Sec., State Board of Health, Dr. R. N. Whitfield, Jackson.

MONTANA: *Reciprocity*. Helena, Oct. 2. *Examination*. Helena, Oct. 3-4. Sec., Dr. S. A. Cooney, 216 Power Block, Helena.

NEBRASKA: *Basic Science*. Lincoln, Oct. 3-4. Dir., Bureau of Examining Boards, Mrs. Clark Perkins, 1009 State Capitol Bldg., Lincoln.

NEVADA: *Written examination and reciprocity with oral examination*. Carson City, Nov. 6. Sec., Dr. John E. Worden, 311 W. Robinson St., Carson City.

NEW JERSEY: Trenton, Oct. 17-18. Sec., Dr. Earl S. Hallinger, 28 W. State St., Trenton.

NEW MEXICO: Santa Fe, Oct. 9-10. Sec., Dr. Le Grand Ward, 135 Sena Plaza, Santa Fe.

NEW YORK: Albany, Buffalo, New York and Syracuse, Sept. 18-21. Chief, Bureau of Professional Examinations, Mr. Herbert J. Hamilton, 315 Education Bldg., Albany.

NORTH CAROLINA: *Reciprocity and Endorsement*. Raleigh, Dec. 11. Sec., Dr. W. D. James, Hamlet.

NORTH DAKOTA: Grand Forks, Jan. 2-5. Sec., Dr. G. M. Williamson, 4½ S. Third St., Grand Forks.

OKLAHOMA: *Basic Science*. Oklahoma City, Nov. 6. Sec. of State, Hon. C. C. Childress, State Capitol, Oklahoma City. *Medical*. Oklahoma City, Dec. 13. Sec., Dr. James D. Osborn, Jr., Frederick.

OREGON: *Basic Science*. Portland, Oct. 28. Sec., State Board of Higher Education, Mr. Charles D. Byrne, University of Oregon, Eugene.

PENNSYLVANIA: Philadelphia, January. Dir., Bureau of Professional Licensing, Dr. James A. Newpher, Department of Public Instruction, 358 Education Bldg., Harrisburg.

RHODE ISLAND: Providence, Oct. 5-6. Sec., Board of Examiners in Medicine, Dr. Robert M. Lord, 122 Waterman Ave., Providence.

SOUTH CAROLINA: Columbia, Nov. 14. Sec., Dr. A. Earle Boozer, 505 Saluda Ave., Columbia.

SOUTH DAKOTA: Pierre, Jan. 16-17. Dir., Medical Licensure, Dr. G. J. Van Heuvelen, State Board of Health, Pierre.

TENNESSEE: Memphis, Sept. 27-28. Sec., Dr. H. W. Qualls, 130 Madison Ave., Memphis.

TEXAS: Austin, Nov. 20-22. Sec., Dr. T. J. Crowe, 918-19-20 Mercantile Bldg., Dallas.

VERMONT: Burlington, Feb. 13-15. Sec., Board of Medical Registration, Dr. W. Scott Nay, Underhill.

VIRGINIA: Richmond, Dec. 13. Sec., Dr. J. W. Preston, 30½ Franklin Road, Roanoke.

WEST VIRGINIA: Fairmont, Nov. 6-8. Sec., Public Health Council, Dr. Arthur E. McClue, State Capitol, Charleston.

WISCONSIN: *Basic Science*. Madison, Sept. 23. Sec., Professor Robert N. Bauer, 3414 W. Wisconsin Ave., Milwaukee. *Medical*. Madison, Jan. 9-11. Sec., Dr. Henry J. Gramling, 507 Mariner Tower, Milwaukee.

WYOMING: Cheyenne, October. Sec., Dr. M. C. Keith, Capitol Bldg., Cheyenne.

Rhode Island July Examination

Dr. Robert M. Lord, secretary, Board of Examiners in Medicine, reports the oral, written and practical examination held at Providence, July 6-7, 1939. The examination covered fourteen subjects and included fifty questions. An average of 80 per cent was required to pass. Five candidates were examined, all of whom passed. Four physicians were licensed by endorsement after an oral examination. The following schools were represented:

School	PASSED	Year Grad.	Per Cent
Tufts College Medical School.....	(1938)	89.2	
University of Buffalo School of Medicine.....	(1934)	81	
Hahnemann Med. College and Hospital of Philadelphia.....	(1938)	82.4, 82.9	
Jefferson Medical College of Philadelphia.....	(1938)	88.5	

School	LICENSED BY ENDORSEMENT	Year Grad.	Per Cent
Yale University School of Medicine.....	(1937)	N. B. M. Ex.	
School of Medicine of the Division of the Biological Sciences.....	(1933)	N. B. M. Ex.	
Tufts College Medical School.....	(1935)	N. B. M. Ex.	
Marquette University School of Medicine.....	(1938)	N. B. M. Ex.	

West Virginia July Report

Dr. Arthur E. McClue, secretary, West Virginia Public Health Council, reports the oral and written examination held at Bluefield, July 5-7, 1939. The examination covered eleven subjects and included 110 questions. An average of 80 per cent was required to pass. Twenty-two candidates were examined, all of whom passed. Twenty-five physicians were licensed by reciprocity and one physician was licensed by endorsement. The following schools were represented:

School	PASSED	Year Grad.	Per Cent
Emory University School of Medicine.....	(1938)	89.6	
Northwestern University Medical School.....	(1939)	83.9, 85.1	
Rush Medical College.....	(1938)	86.2, 87.7	
Washington University School of Medicine.....	(1934)	88.4	
Duke University School of Medicine.....	(1933)	82.4, (1937)	84.6
Hahnemann Medical College and Hospital of Philadelphia.....	(1938)	83.1, 83.8	
Jefferson Medical College of Philadelphia.....	(1938)	90.5	
Medical College of the State of South Carolina.....	(1938)	86.3, 85.1	
Medical College of Virginia.....	(1938)	84.3	
University of Virginia Department of Medicine.....	(1936)	86.4	
University of Wisconsin Medical School.....	(1938)	87.8	

School	LICENSED BY RECIPROCITY	Year Grad.	Reciprocity with
University of Arkansas School of Medicine.....	(1917)	Tennessee

Book Notices

The Patient and the Weather: Volume I, Part 1. The Footprint of Asclepius. By William F. Petersen, M.D. Cloth. Price, \$3.75. Pp. 127, with 94 illustrations. Ann Arbor: Edwards Brothers, Inc., 1935.

With the appearance of this relatively slim printed volume, Petersen's monographic work on the relationship of the weather to disease is both commenced and completed. Reviews of volumes I, III and IV, the latter divided into three parts, and the second half of volume I, have already appeared in these pages, and Petersen's thesis relative to the changes in the capillary bed due to the weather has been summarized so that those who are interested in this phenomenon already have an idea of what he has been driving at. This introductory volume, the only one which is printed—the others were lithoprinted—gives a background of Petersen's extensive study. It discusses to some extent Greek medicine and to a great extent the attitude of Hippocrates toward weather changes with a regard to disease, which can be summed up in the words "All diseases are fundamentally due to interference with oxidation." The remainder of the volume is devoted primarily to a discussion of disease distribution throughout the nation derived chiefly from the reports of physical defects found in drafted men during the war. While the specific correlation of cyclonic changes in this country as related to individual diseases is left to the later volumes, a briefly explanatory presentation is included in this volume I, part I, called "The Changing Restlessness of Winds in America." There is some discussion of what the author calls "racial differentiation," but the matter of race is not highly differentiated and is neglected to some extent in this chapter. Since this is the last volume to appear, it might be well to call attention to the fact that Petersen has now presented a vast amount of material, some of which is highly impressive, and other evidence which seems to be bizarre, to show that changes in cyclonic front and weather conditions and weather zones and other atmospheric changes have a marked influence on illness in this country. The work has been painstakingly done. A great deal of anatomic and pathologic material has been presented, including excellent illustrations. Each disease has been carefully analyzed and specific cases, described in great detail, have been utilized to illustrate the facts presented. While it may be still considered doubtful whether Petersen is justified in the conclusions which he draws relative to the effect of weather on changes of oxidation in the relatively self-contained and automatically biochemically balanced human body, those who are interested in the effect of weather on a specific disease or in this problem as a whole would do well to bear in mind his study if they desire to gain a thorough understanding of any or all of the pathologic processes of mind or body.

The American Criminal: An Anthropological Study. By Earnest Albert Hooton, with the collaboration of the Statistical Laboratory of the Division of Anthropology, Harvard University. Volume I: The Native White Criminal of Native Parentage. Cloth. Price, \$10. Pp. 309, with an appendix of 480 pages of tables. Cambridge, Massachusetts: Harvard University Press; London: Oxford University Press, 1939.

For some years Professor Hooton and his students have been making an anthropologic study of criminals. They have been visiting penal institutions in a number of states and have been surveying the inmates from the standpoint of their anthropologic backgrounds with relationship to the specific crimes they have committed. In his earlier semipopular summary "Crime and the Man," Hooton brought out the fact that there are differences between the old American stock, the immigrant of various stocks and the Negro offenders with regard to their criminal behavior. Some of their conclusions agreed with what criminologists have always believed, others have been confictual. The present report, on the native white criminal of native parentage, is an expansion of part of "Crime and the Man" intended apparently for serious students of the subject having a highly technical anthropologic background. About half of the volume is devoted to discussing general principles and the observations of criminology as the author and others see them, while the other half consists of tables dealing with occupation, size, age and physical characteristics of a particular criminal group, going into such details as

thickness of lip integument, hair color and lombrosian characteristics. The general conclusion reached by Hooton with regard to this group of Old Americans is that crime is the result of the impact of environment impinging on an inferior constitution. It is his belief that Lombroso late in the last century brought forth this idea, that Hooton's own observations substantiate him, although Lombroso fallaciously emphasized his stigmas of degeneration, a collection of traits not verified in the present project. He makes a multiplicity of comparisons with regard to age, size and other physical features, and he includes rather superficial sociological factors differentiating, for instance, criminals in various states. He also differentiates criminals in various crime groups although he admits that the grouping of violations according to the type of offense resulting in conviction is erroneous. By implication Hooton admits that his results are probably not of any value in detecting criminals and that there is little in the book to indicate that it will be of much value in correcting criminal tendencies. His idea of inferior individuals is largely on an anthropologic basis: he leaves out of account almost entirely the psychologic factors which are involved in crime. The volume has no direct bearing on psychologic medicine, and while it involves a great deal of painstaking work it is questionable in its practical application. Hooton's theoretical implications must be taken into consideration bit by bit and no general conclusion can be drawn relative to the scientific value of the vast mass of unrelated and related data which form this volume, although one may well question whether the energy expended on this work might not have been more socially profitable if turned into other channels.

Sex and Internal Secretions: A Survey of Recent Research. Editor: Edgar Allen, Associate Editors: Charles H. Danforth and Edward A. Dolsey. With forewords by Robert M. Yerkes. Second edition. Cloth. Price, \$12. Pp. 1,346, with illustrations. Baltimore: Williams & Wilkins Company, 1939.

It has been generally considered that the first edition of this book served as an invaluable guide for the student and investigator of the biology and physiology of the sex organs. The various chapters reviewing the progress in these subjects to 1933 were composed by men who were leaders in developing these fields. It was natural therefore that these reviews were ably presented and the numerous experimental facts soundly evaluated.

Since 1933 the rapidity with which data have been reported has led to considerable confusion in the minds of all except those intimately associated with the literature. Many students and physicians have in the past neglected the adequate study of these important subjects because of the uncertain state of the physiologic and endocrine aspects of sex and the belief that current concepts were only temporary and apt to change from day to day. Recently, however, there has been appreciable abatement in the furor of publication, with the more or less conclusive establishment of many of the relatively elementary principles. Unless revolutionary discoveries are uncovered, it appears likely that further developments will be more orderly than those of a few years ago. At the present time much of the chaff has already been separated from the grain. Questionable results have been exposed and considerable early overenthusiasm has been dissipated. Sufficient advance has been made to give our present knowledge a greater stability and future progress a more dependable character. Under these circumstances, physicians should no longer hesitate to undertake an appropriate study of the functions of reproductive organs and their relation to other bodily activities.

The appearance of the second edition is therefore timely. It is needless to say that investigators in the field have been anxiously awaiting its publication. Physicians and students who are not sufficiently acquainted with the literature are fortunate to have available this monumental review, where there can be found the essence of our knowledge presented with much discrimination. The book is naturally an academic presentation, but the physician who is treating functional disturbances of the reproductive organs is urged to search here for the principles on which to base his therapy. It is only in this way that satisfactory progress in the clinic will be accomplished. The modern gynecologist should find this volume indispensable. Much of the material may appear complicated and unnecessary for prac-

tical purposes, but a satisfactory understanding of the subject necessitates a thorough study of the actual experimental facts from which conclusions have been drawn.

The plan of the book is, in general, quite similar to that of the first edition. There are five sections: (1) biologic basis of sex, (2) physiology of the sex glands, germ cells and accessory organs, (3) biochemistry and assay of gonadal hormones, (4) the hypophysis and gonadotropic hormones of blood and urine in relation to the reproductive system and (5) additional factors in sex functions and endocrine application in man. Many of the chapters, such as those on the biochemistry of sex hormones, have been extensively revised and expanded. Several entirely new chapters have also been added. The authors are mainly those who were responsible for the first edition and were uniformly well selected for their tasks. The Committee for Research in the Problems of Sex, National Research Council, sponsored the publication of this remarkably fine survey.

Encefalitis postneumonica en el niño. Por José Bonaba, Director, y Carlos M. Barberousse, jefe de clínica. Facultad de medicina de Montevideo (Uruguay), Instituto de clínica pediátrica y puericultura "Dr. Luis Morquio," Colección de monografías. Monografía N.º 3. Paper. Pp. 45, with 9 illustrations. Montevideo: Imprenta "Rosgal," de Hilario Rosillo, 1939.

This is monograph 3 from the pediatric clinic of Dr. Luis Marquío in Montevideo. Abstracts and tables are given of twenty-eight cases in children ranging in age from 14 months to 12 years. Most of them have previously been published in South American, French and Italian journals. No publications in English or German are mentioned. Of the twenty-eight cases, six terminated fatally. The gross and microscopic lesions in the brain in one case are described and illustrated. On the sixth day of lobar pneumonia a violent convulsion set in followed by coma. The bilateral Babinski sign was present, the knee reflexes were normal and there was no rigidity. The spinal fluid showed no increase in cells or globulin. Death was twenty-seven hours after the onset of brain symptoms. Infiltrative and degenerative changes were found in the striatum and thalamus (while the substantia nigra escaped). The cortex showed only congestion. In the only other case examined microscopically of which the authors are aware, studied by Lhermitte, the lesions were purely degenerative.

The Startle Pattern. By Carney Landis, Ph.D., Research Associate in Psychology, Psychiatric Institute, New York, and William A. Hunt, Ph.D. With a chapter by Hans Strauss, M.D., Assistant in Psychiatry, Columbia University, New York. Cloth. Price, \$2.50. Pp. 168, with 4 illustrations. New York: Farrar & Rinehart, Inc., 1939.

This is a rather extensive report of a simple series of experiments of a type only too seldom seen in this country. The writers begin with the simple startle pattern which has been described so often but primarily studied by Strauss, who contributes two chapters to the volume. The startle pattern is the reaction of an individual to a sudden sound, whereby he blinks his eyes and goes through various contortions. Since contortions have been described in different ways by various reporters, it was thought that careful study of the simple phenomenon would be revealing, as it proved to be. The technic used was to take extremely rapid moving pictures, sometimes reaching two or three thousand exposures per second, and to do this a number of technical details had to be overcome. While the authors did not go into the detailed solution of these problems, it is possible, by reading between the lines, to note the fact that these solutions were achieved. Hundreds of patients were studied. Infants, psychotic individuals, epileptic patients, animals and neurologic cases, as well as the normal, were given a thorough investigation. It is interesting to note that the catatonic schizophrenic, who would be least apt to be expected to act in a startled fashion, were hyperreactive, while other presumably more reactive types of psychoses were slowed down. The hard of hearing patients might again be thought to have a modified startle pattern, but there was only one case in this particular group in which modification was noted. The whole study reveals leads to the psychologist, psychiatrist and neurologist that a simple diagnostic procedure may be devised which would aid in further differentiating pathologic problem cases. The authors did not point out just how this is to be done, although there are some implications. An excellent bibliography is appended.

The Postnatal Development of the Human Cerebral Cortex. By J. LeRoy Conel. Volume 1: The Cortex of the Newborn. Cloth. Price, \$8. Pp. 114, with 98 plates. Cambridge, Massachusetts: Harvard University Press; London: Oxford University Press, 1939.

This book, which is clearly printed and beautifully illustrated, is a masterpiece of work. The study is being carried out in the Department of Anatomy of the Boston University School of Medicine and the Department of Pathology of the Harvard Medical School in the Children's Hospital and the Infants' Hospital. In the introduction Conel states that the investigation is intended to be a general survey of the postnatal development of the nerve cells in the normal human cerebral cortex. This volume describes the state of development of the neurons in the cerebral cortex of the nine month fetus immediately after birth. All the brains used were obtained from necropsies done within twenty-four hours after death. Great care was used in accepting brains for the study. Six brains were used, four from white male and two from white female infants. Ten per cent formaldehyde was used as a fixing agent. Celloidin and paraffin were employed as embedding material. The methods utilized were staining with cresyl violet, Cajal silver impregnation and the Golgi-Cox and Weigert methods. The average weight of the brains was 335 Gm. The contents of the book consist of chapters on the histology of the lobus frontalis, parietalis, occipitalis, temporalis, insulae and rhinencephalon, as well as a general summary, tables, literature and illustrations. These are unusually well done. There is a surprisingly small bibliography in this special field. The book is highly recommended to all neurologists, neurosurgeons, pediatricians, anatomists and histologists. This contribution will be utilized and referred to frequently.

Biographies of Child Development: The Mental Growth Careers of Eighty-Four Infants and Children. A Ten-Year Study from the Clinic of Child Development at Yale University. Part One. By Arnold Gesell, Ph.D., M.D. Part Two. By Catherine S. Amatruda, M.D., Burton M. Castner, Ph.D., and Helen Thompson, Ph.D. Cloth. Price, \$3.75. Pp. 328. New York & London: Paul B. Hoeber, Inc., 1939.

The prediction of growth in childhood, both mental and physical, has been a matter of much conjecture, and many claims have been offered by so-called students of the subject tending to credit or discredit the intelligence quotient as a predictive means and also the value of growth tables. The present volume clarifies the matter to some extent and is highly enlightening as to the fact that there are many elements responsible for normal and atypical growth in both these spheres. Gesell and his colleagues in the Clinic of Child Development at Yale University have been studying these cases for ten years, and the book consists largely of eighty-four short or longer case reports, each designed especially to bring out some feature of development which would be of interest. Some of the cases show clearly how definitely predictive the growth curve or the intelligence test is. Other cases show that, knowing atypical factors such as hypothyroidism, birth injury or some other diagnosable disorder which might interfere with growth, one can partly make a prediction on a basis of the usual normal growth curve. More interesting than this principle, however, are the examples of a large number of cases in which the early development was retarded but, as the result of treatment or for some other reason, the child either assumed the predicted rate or quickly advanced beyond it because of capacity for superior growth, particularly in the mental sphere. Many features such as the influence of physical disease are considered, and parts of the book devote some space to special disabilities such as reading defects and language problems. Immaturity, twinship and foster care are taken up and cases are cited in all the spheres considered, running the gamut from retardation due to some factor which is pointed out to marked natural advancement. While it might be difficult for one who is not fully acquainted with the literature and procedures of child study and child guidance to gain much from a case-study volume of this sort, the whole book presents an excellent argument in favor of careful child study from the standpoint of the pediatrician and psychiatrist and implies that predictions as to spontaneous cure or even the continuation of normal development must be made with some care. On the other hand, hope is given to those who have to deal with problem children in that many are shown not only

to recover and to reach the normal curve but to advance far beyond the average into the superior range. This book would be valuable for the child psychologist and the physician who has to do with developing children—the pediatrician or the orthopsychiatrist. It is scientifically done and carefully prepared, the cases are well selected and, while some perhaps are too short to show the mechanisms at work, at least they do show the principle involved in the success or failure of the child to develop.

La puberté: Etude clinique et physiopathologique. Par Guy Laroche et al. Paper. Price, 65 francs. Pp. 349, with illustrations. Paris: Masson & Cie, 1938.

This is one of those French symposiums which contain contributions by a number of reporters, some leading in the profession, others relatively unknown, some expert and some inexpert, some with literary ability and some with none. Puberty is considered here largely from a physical standpoint, though there is one chapter devoted to the psychologic problem of puberty. Such physical disorders as glandular changes, cutaneous reactions both normal and pathologic, obesity and sexual changes are discussed in rather satisfactory chapters. There is some discussion of tuberculosis and diseases of the eye, but the whole volume is not so well systematized that every possible disorder of puberty is covered and some are dismissed disproportionately to their significance. A particular example of this is an extensive report on exophthalmic goiter, which is given much more space than the number of hyperthyroid children found in the population would deserve. Since the chief problems of puberty, as recognized in this country, are those of social adjustment and mental development, it is unfortunate that these are not sufficiently recognized in France so that a thorough discussion of them might appear in this volume. The physical disorders, after all, are not as a rule confined to the period of puberty and the discussion of them with regard to this period cannot be strictly held to that relationship. This book has all the weaknesses of a symposium; probably its greatest strength is service to the idea that there are clinicians who would be interested in knowing the special changes and deviations that occur during puberty. These changes and deviations, unfortunately, are not as well dealt with as they should be, for the actual stressing of disease should not overshadow interest in the social and psychiatric problems of the puberal period.

Outline of Psychiatric Case-Study: A Practical Handbook. By Paul William Preu, M.D., Assistant Professor of Psychiatry and Mental Hygiene in the Yale University School of Medicine, New Haven. With foreword by Eugen Kahn, M.D. Cloth. Price, \$1.85. Pp. 140. New York: Paul B. Hoeber, Inc., 1939.

This is a small volume intended to give the physician a comprehensive yet practical means of making a psychiatric examination. It is an improvement on the older manuals such as the manual of Cheney and is devised to present primarily an outline which the inexperienced psychiatrist can follow provided he is given guidance, definition of terms and advice about what the various symptoms and signs into which he is looking mean. The construction of this guide is substantially what one would expect; namely, about half of it is devoted to an outline of psychiatric history taking and the other half an outline of the mental examination. The paragraphs are brief, there is much abbreviation, and in a number of places words are inserted in lieu of extended explanations. In such a case it is obvious, of course, that the beginner or the nonpsychiatrically trained person would be obliged to have ancillary information if he wished to use the present volume as a guide. In some places the author shows a lack of knowledge of terminology used outside the field of psychiatry, for in examining mental changes in the visual sphere he uses the term "visual field," which of course applies to campimetry. Errors of this sort are not common in the book, however, and as a whole it can be considered a useful little handbook for the beginner provided he is given training and does not depend entirely on this volume. Most teachers, however, will find that it is more profitable to use their own methods of teaching how to make a psychiatric examination; but in lieu of the teacher's own guide the present volume is the best of its kind that has been produced so far to serve its purpose.

The Stag at Ease: A Cookbook. Being the Culinary Preferences of a Number of Distinguished Male Citizens of the World. Compiled by Marian Squire. Cloth. Price, \$2. Pp. 164. Caldwell, Idaho: Caxton Printers, Ltd., 1938.

This is a culinary scrapbook giving the favorite recipes of a number of distinguished male citizens of the world. As with all such collections, the reviewer wonders why every one of these famous people likes something different. Of course they do not. Many of them must prefer corned beef and cabbage. A great many must, as does Louis Bromfield, pick vegetable soup; no doubt this would apply to many another one of the recipes. The book is assembled cleverly and is full of fascinating information. H. L. Mencken likes varied food but at present prefers Chesapeake crabs. Christopher Morley's favorite breakfast is fried apples with Philadelphia scrapple and toasted corn pone. Ogden Nash can eat shad roe and bacon until the shad go home. Ed Sullivan likes Irish stew, and T. S. Stribling likes fried chicken livers. Mark Sullivan says it is "sirloin steak with fried onions, endive salad," and thus the list goes on.

Psychopathic States. By D. K. Henderson, M.D., Professor of Psychiatry, University of Edinburgh, Edinburgh. Cloth. Price, \$2. Pp. 178. New York: W. W. Norton & Company, Inc., 1939.

This is a small volume, one of a series of books each containing the annual lectures given in the series dedicated to the memory of Dr. Thomas W. Salmon. The material given here about psychopathic states is not new but it is extremely well presented. The book consists of a short historical introduction containing a discussion of the various components producing conduct disorders, but most of the volume is devoted to a discussion of the clinical manifestations of the psychopath. Henderson divides the psychopathic states into those characterized primarily by, first, aggressive conduct. In this group he discusses suicides and criminal individuals. The second group are those characterized primarily by inadequacy, in which the psychotoids and borderline psychopathic cases are analyzed. Third, Henderson discusses the group of "near genius" conditions. The last chapter treats of social rehabilitation and here the various angles such as psychic immaturity and the influence of fear are taken up briefly, but in it there are discussions of the various steps used in Scotland to deal with the whole problem. In a mild way Henderson advocates assistance on the part of the states toward the rehabilitation of the psychopathic patient, and he feels that mental physicians should not be too much discouraged at their lack of success in treating these conditions at the present time but should remember that the field of therapy is opening widely. There is much brief but interesting case history material; discussion is lucid; and while Henderson calls himself a liberal the present book seems rather conservative to the American mental hygienist in its approach to the subject. It could be perused with interest and satisfaction by the physician who wants a better knowledge of the psychopath.

Your Health Dramatized: Selected Radio Scripts. By W. W. Bauer, B.S., M.D., Director, Bureau of Health Education, American Medical Association, and Leslie Edgley of the National Broadcasting Company. Cloth. Price, \$2.25. Pp. 528. New York: E. P. Dutton & Company, Inc., 1939.

The individual physician concerns himself with health education of the public only as far as it affects his immediate practice. More often today than before does he accept the part of health teacher in that he gives generously of his time for addresses before school audiences, parent teacher association groups and various civic societies. The use of the dramatic technic in presenting health information is rarely within his scope. The various county and local medical societies are beginning to look to this form of presenting health information. This volume enables various groups to put on dramatized episodes giving health information. While the original purpose of the book has been to adapt original scripts to meet the need of classroom or assembly, it can well serve as a basis for broadcasts over local stations. The scripts in this volume were adapted from those originally broadcast by the American Medical Association and the National Broadcasting Company in the Your Health series. The Institute for Radio in Education, at its ninth annual session at Ohio State University in 1938, after hearing transcripts of typical programs from the 1937-1938 series, gave the Your Health program a

first award in the health classification. Thirty-two subjects are given and attractive titles are by no means the least in valuable information given. Thus the title "Who Chooses Your Doctor?" will do much to gain the attention of the listening public. A title such as "Hospitals Aid Health" and "The Health Check-Up" will also encourage the casual listener to make sure that he hears that particular program. A title such as "Living With People" is much more attention arresting than would be one on mental hygiene. This is a book that can be enthusiastically recommended to the health educator who wishes to use the newest of all technics at his command.

The Clinical Diagnosis of Swellings. By C. E. Corrigan, B.A., M.D., F.R.C.S., Lecturer in Surgery, University of Manitoba, Winnipeg. Cloth. Price, \$4. Pp. 313, with 120 illustrations. Baltimore: William Wood & Company, 1939.

The author states clearly the purpose of this book in the preface, "to present a simple practical method of investigating swellings in order to clarify the problem of their diagnosis." Clinical methods and physical signs form the framework on which the diagnosis of swellings is made. There is consideration of the general diagnosis of swellings, of inflammatory and granulomatous swellings, of tumors, cysts and ulcers, of enlarged lymphatic glands and of swellings of the neck, breast, abdomen, groin, scrotum and about joints. Presentation is excellent and aided greatly by first rate illustrative drawings. This is a unique book and a valuable one, for every practicing physician must be puzzled occasionally about the correct diagnosis when his patient has a "swelling." Most teachers of physical diagnosis, most students and most physicians will find the book valuable and interesting. In these days of modern laboratory diagnosis it is refreshing and heartening to know that intelligent use of the eyes, the ears and the hands can frequently lead to a correct diagnosis which is firmly based on simple physical phenomena.

Pastoral Psychiatry. By John Sutherland Bonnell. With a foreword by Thaddeus Hoyt Ames, M.D. Cloth. Price, \$2.50. Pp. 237. New York & London: Harper & Brothers, 1938.

One must be out of sympathy with the minister who passes under false colors. By stressing the Greek derivation of the word psychiatry the author, a pastor, turns psychiatry from a medical specialty to mean merely treatment of the mind, and on perusal of this opus one finds a number of examples of how a nonmedical man goes about correcting personality problems and aiding people. One of the most serious indictments against the ministry as regards its contact with mental cases is the fact that it almost always enhances feelings of guilt—a dangerous process; yet the outcome of the cases as presented in Bonnell's book all seem to be satisfactory, indicating a highly select body of illustrative material. Nevertheless, if the type of advice given by him as shown by some of his examples were given to individuals with deep sexual guilty feelings, serious harm or regression, even to insanity, might frequently result. The book begins by the author's describing his own experiences as a son of an old-fashioned asylum superintendent and worker in a mental institution. He presumes that this could give him insight into mental cases. What he seems to know of psychiatry is distinctly passé. There is no question that a psychiatrist and a minister can work together well in correcting certain types of mental disorders, but knowing Bonnell's ideas on psychiatry, as presented here, a modern psychiatrist might find it hard to consult with him.

The Races of Europe. By Carleton Stevens Coon, Assistant Professor of Anthropology, Harvard University, Boston. Cloth. Price, \$7. Pp. 739, with illustrations. New York: Macmillan Company, 1939.

This is a contribution to the science of physical anthropology, tracing the development of man down through the ages and giving the scientific background of the modern European. The book reveals what a welter of mixtures Europe actually represents. Especially interesting is the chapter which indicates that, even though the Jews themselves in Europe constitute a mixture of a variety of types and stocks, they are relatively more pure than any other stock in Europe. For instance, "The racial character of the Spanish, the Germans, of the Poles and of the Russians has changed much more during the last millennium than has that of the Jews."

The Massachusetts General Hospital: Its Development, 1900-1935. By Frederic A. Washburn, M.D. Cloth. Price, \$4. Pp. 643, with 13 illustrations. Boston: Houghton Mifflin Company, 1939.

This is the fifth book written on the history of the Massachusetts General Hospital and is aimed at describing the development of the hospital from 1900 to 1935. In a number of the subjects considered, however, the roots go further back than 1900, and where material was found which had not appeared in earlier histories it has sometimes been used here. The history of this hospital is intimately associated with the growth of teaching hospitals in general and with the improvement in medical education and hospital facilities throughout the country. To thousands of individual physicians this history has a more intimate appeal as the institution to which they themselves contributed. This is an excellent source book for information, but the reading is difficult since it constitutes in large measure—perhaps unavoidably—a catalogue of the names of trustees, administrative officers, donors, physicians and physical plant expansion.

The Open Mind: Elmer Ernest Southard, 1876-1920. By Frederick P. Gay. With an introduction by Roscoe Pound. Cloth. Price, \$5. Pp. 324, with 13 illustrations. Chicago, Illinois: Normandle House, 1938.

This is a biography of Dr. Elmer Ernest Southard, a pioneer in modern mental hygiene and psychiatry, a public spirited citizen and social worker, and a scientist. The book is written in pleasing style, supplemented by excellent illustrations, anecdotes and comments. There are most interesting examples of Dr. Southard's contributions to poetry and a bibliography of his writings. The book is a valuable contribution to every medical-historical collection and will be of especial interest of course to those in the field of psychiatry.

Comparative Studies Concerning the Strengths of Oestrogenic Substances. By Kaj Pedersen-Bjergaard. Denne Afhandling er af det matematisk-naturvidenskabelige Fakultet antaget til offentlig at forsvares for den filosofiske Doktorgrad, København. Paper. Price, 15 kroner. Pp. 198, with 29 illustrations. Copenhagen: Einar Munksgaard; London: Oxford University Press, 1939.

This monograph is limited to a discussion of the isolation, composition, structure, properties and assay technics of the various estrogenic substances. After a brief outline of the work of the various investigators in this field there is a large section devoted to the author's own investigations. The purpose of the monograph is to compare the activity of the various estrogens under different conditions of administration, i. e. subcutaneous or oral, in oil or water solution, single or multiple injections. These are discussed in great detail, as can be judged by the fact that the author presents twenty-nine charts and 141 tables of his protocols. From a practical point of view this monograph can be summarized rather briefly. There is little here to interest the physician not specializing in this field.

A Short Encyclopaedia for Nurses. By Evelyn C. Pearce, Sister Tutor, The Middlesex Hospital, London. Cloth. Price, \$3.50. Pp. 686. New York: E. P. Dutton and Co., 1939.

This short nursing encyclopedia is a cross between a nursing dictionary and a nursing textbook. The material, while abbreviated, covers a wide field and has been selected for practicality. It has been condensed for maximum usefulness. Various diseases, surgical and medical conditions, diagnoses, treatment, diet, abbreviations, apothecary systems and great names have all been included. The more common conditions, such as appendicitis, are naturally given more attention than miners' nystagmus, for which a sentence or two suffices. Timely new drugs, such as sulfanilamide, are discussed. The doses suggested for sulfanilamide would be considered totally inadequate in American hospital practice. Well indexed, this book has a real place on the reference shelf of a hospital library.

The Hippocratic Oath. By Edgar Leon Dittler. Cloth. Price, \$2.50. Pp. 310. New York: Liverlight Publishing Corporation, 1938.

Even in the mass of medical fiction, nonfiction and essays which have been offered to the public in recent years, this novel by Dittler has a very small place. It brings up the old question of whether or not an intern and a physician can avoid the temptation of sordidness and money and remain true to their ideals. Obviously there are a few who cannot, but the vast majority can. All the old situations of life and love in the hospital are here reflected without much literary quality.

Truth About Cosmetics. By Everett G. McDonough, Ph.D. Cloth. Price, \$5. Pp. 311. New York: Drug and Cosmetic Industry, 1937.

In this volume, which is published by the drug and cosmetic industry, the author presents a history of cosmetics and perfumes, a few statements on the subject of cosmetic dermatitis and a general consideration of all sorts of cosmetic preparations. The volume is definitely written for rather than against cosmetics, so that its author is apparently willing to condone the use of metallic salts for removing pigment when the best medical advice is certainly against the uncontrolled use of such preparations. The final chapter deals with treatments for obesity and tries to be as kind as possible to drugs for obesity that are based on bladder wrack without saying at once that all such preparations are pure hokum. The author seems to believe that the use of hypertonic solutions for bathing dries out the body.

Beware Familiar Spirits. By John Mulholland. Cloth. Price, \$2.50. Pp. 342, with illustrations. New York & London: Charles Scribner's Sons, Ltd., 1938.

There have been innumerable exposés of the spiritualists. Mr. Mulholland, who has been for many years a student of the subject and who is himself famous as a magician, has investigated the manner in which the spirits are raised. He exposes the inside of the subject. There are still plenty of people who believe that the spirits can be raised, and their notes are also included in this volume. For those interested in keeping up with the latest "dope" on the spirits the book will be found useful and interesting.

Health for 7,500,000 People. Annual Report of the Department of Health, City of New York for 1937 and a Review of Developments from 1934 to 1938. John L. Rice, M.D., Commissioner of Health. Cloth. Pp. 390, with illustrations. New York. [n. d.].

The general death rate in New York in 1937 was 10.4 per thousand of population. The best previous record was 10.3 in 1935; it was 20.6 in 1900. Infant mortality was 135.3 per thousand live births in 1900 and 43.7 in 1937. Maternal mortality fell from 6 per thousand live births in 1933 to 4 in 1937. The department budget, exclusive of capital outlay, was \$4,725,817.90 and covered a pay roll of 2,567 employees. "The Department of Health's policy is to urge all who can possibly afford it to use the services of private physicians." There is close cooperation with the three county medical societies, especially in maternal and infant care. "In marked contrast to conditions in this city fifty years ago, and still prevailing in many European countries, modern health administration makes little use of police measures and carries on most of its work through health education."

Textbook of Anatomy and Physiology. By Diana Clifford Kimber, Carolyn E. Gray, A.M., R.N., and Caroline E. Stackpole, A.M., Associate in Biology, Teachers College, Columbia University, New York City. Tenth edition. Cloth. Price, \$3. Pp. 643, with 276 illustrations. New York: Macmillan Company, 1938.

The fact that this standard textbook on anatomy and physiology intended for nurses has reached its tenth edition means that the book has been tried and found to be useful, authoritative and readable. The new edition is superior in many ways to the previous editions. The illustrations are excellent. Many of the old illustrations have been redrawn and thirty new ones added. The authors have tried to keep the material abreast of the time by rewriting portions of the text that present new developments and new knowledge. The volume can be heartily recommended as an authoritative, well written, attractively bound textbook.

Diets and Recipes and the Treatment of Diabetes and Obesity. By E. P. Poulton, M.A., D.M., F.R.C.P., Physician to Guy's Hospital, London. Cloth. Price, \$2.75; 7s. 6d. Pp. 121. New York & London: Oxford University Press, 1937.

Difficult, indeed, is the task of the physician who must carefully select a diet for the diabetic patient and for those who want to reduce, but here is a book by a physician from Guy's Hospital to help. It provides all the necessary data concerning foods, a number of excellent sample diets and much simple information concerning the routine care of the diabetic and the overweight patient. For those who are really in earnest and willing to study, this is a most useful volume.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Criminal Insanity: Testimony of Alienists Not Conclusive.—In a prosecution for murder the defendant Arridy, who was a ward of a state institution for feeble-minded, mentally defective and epileptic persons, pleaded not guilty by reason of insanity. He was committed to the State Hospital at Pueblo, Colo., for observation for a period of thirty days, and a commission of three alienists, physicians at that institution whose professional qualifications and integrity were unquestioned, was appointed to examine his mental condition. The commission reported that in its opinion Arridy was "mentally defective" and that at the time of the alleged commission of the crime he was "incapable of distinguishing between right and wrong, and . . . unable to perform any action with a criminal intent." The state, however, introduced lay testimony to the effect that the defendant was sane at the time that the homicide was committed. The defendant was adjudged sane by a jury and from a judgment convicting him of first degree murder and imposing the death penalty he brought error to the Supreme Court of Colorado.

The testimony of the alienists, said the Supreme Court, was not conclusive as to the defendant's mental condition. The question as to whether or not he was criminally insane was for the jury to decide and it was justified from the evidence in finding that he was "sane at the time of the commission of the alleged offense." In the judgment of the court, the evidence established only that he was weak minded. Accordingly, the judgment of conviction was affirmed.—*Arridy v. People (Colo.)*, 82 P. (2d) 757.

Malpractice: Hemostatic Forceps Left in Abdomen.—McGrady was operated on for "stomach ulcers" in 1931. He seemed to have been in normal health for two years thereafter and apparently no effort was made in the course of the trial of the present case to show that hemostatic forceps were left in his abdomen at this first operation. After two years, however, McGrady's stomach began to trouble him. On March 7, 1935, he vomited blood, and one of the defendants, Dr. Brink, was called in. Nine days later another of the defendants, Dr. Lyman, operated for what the reported decision refers to as a "marginal ulcer" of the stomach. The patient made satisfactory improvement for a few days, but on March 20 he suffered a severe pain in the "mid epigastrium." Thereafter he failed rapidly until he died March 22. The undertaker claimed that he found in the abdomen of the deceased a hemostat about 5 inches long "attached to some of the tissue." McGrady's widow, as administratrix of his estate, sued the two physicians who had been in attendance and others for wrongful death. The jury returned a verdict in her favor and the defendants appealed to the Supreme Court of Washington.

While the evidence as to whether or not a hemostat had been found in McGrady's body was conflicting, the Supreme Court regarded the verdict of the jury as determinative of that fact. The defendants did not deny that leaving a hemostat in the patient's abdomen, if one were left there, would constitute negligence, but they contended that the evidence failed to show that such negligence, if there was any, was the proximate cause of death. But, said the Supreme Court, if there was any substantial evidence from which the jury could conclude that a hemostat left in McGrady's abdomen caused the change in his condition that resulted in his death, the verdict of the jury was controlling.

A medical expert called by the plaintiff testified that if a hemostat were left in the abdomen attached to tissue, the tissue would die and deleterious toxins would arise from it; that those toxins would be absorbed into the blood stream; that the hemostat in the abdomen would probably cause pressure on the bowels and thus cause the severe pain suffered by the deceased, and that, in his opinion, the "hemostat would naturally in the ordinary course of events cause death." He subsequently testified that he did not know what was the cause of death. This, in the opinion of the Supreme Court, did not

destroy the effect of his previous testimony, because no one knew what did cause death. Even the defendants and their expert witnesses did not testify that they knew the cause of death.

The defendants and their expert witnesses, speaking generally, attributed death to one of three causes, and the defendants claimed the benefit of the rule that where the evidence goes no farther than to show that death may have resulted from any one of several causes, for one or more of which the defendant is liable and for another or others of which he is not, the jury cannot speculate or conjecture and return a verdict attributing the death to a cause for which the defendant is liable. The plaintiff, however, said the Supreme Court, charged directly that the death resulted from a single cause, namely, the leaving of the hemostat in the abdomen. The rule under which the defendants sought protection, therefore, did not apply. In determining whether the case presented a question for the jury, the defendants' evidence purporting to show that death was the result of one of two or three causes could not be taken into consideration. The weight of that evidence as against the evidence offered by the plaintiff was for the jury to determine, and the jury had a right to find that it was more probable that the change in McGrady's condition and his subsequent death were proximately caused by leaving a hemostat in his abdomen than by any other cause.

The judgment in favor of the plaintiff was affirmed.—*McGrady v. Brink (Wash.)*, 81 P. (2d) 800.

Criminal Liability Under Compulsory School Attendance Law of Parent of Unvaccinated Child Excluded from School.—A Pennsylvania statute requires a parent of a child of school age to send the child to school. Another statute requires an unvaccinated child to be excluded from school. The state has no compulsory vaccination law. Marsh was convicted of violating the statute first cited "by rendering his son ineligible for admission to the schools of the state by refusing to have him vaccinated against smallpox" and was sentenced to imprisonment. Claiming that his conviction and imprisonment violated the equal protection and due process clauses of the federal Constitution, he filed a bill in the federal district court, M. D. Pennsylvania, to enjoin the governor and others from enforcing the provisions of the compulsory school attendance law as interpreted by the courts of the state. In the bill of complaint he set out as reasons for refusing to comply with the state law that "vaccination against smallpox may cause loss of life, or health, and that vaccination is not a proper or effective method of preventing smallpox." The defendants, in effect, demurred to the bill of complaint.

The two Pennsylvania statutes, said the district court, have been upheld by the highest courts of the state as a valid exercise of the police power. The superior court of Pennsylvania has sustained the conviction of a parent charged with failing to send his child to school on a showing that the parent in question refused to allow the child to be vaccinated and in consequence rendered the child ineligible for attendance. *Commonwealth v. Butler*, 76 Pa. Super. 113. While a federal district court, said the district court, may under certain circumstances enjoin state officials from enforcing a state statute on the ground that it violates the Constitution of the United States, it has no jurisdiction to restrain state officials from enforcing the penal provisions of state statutes as interpreted and enforced by the highest state courts. The complainant should exhaust the remedies available in the state courts and then appeal to the Supreme Court of the United States if the federal Constitution is involved.

Although it declined to assume jurisdiction, the court cited the case of *Jacobson v. Massachusetts*, 197 U.S. 11, 25 S. Ct. 358, 49 L. Ed. 643, in which the Supreme Court of the United States held that a Massachusetts statute requiring compulsory vaccination was not contrary to the Fourteenth Amendment of the United States Constitution, stating that it was for the legislature and not the courts to determine in the first instance whether vaccination is the best mode for the prevention of smallpox. In the opinion of the district court, the two Pennsylvania statutes involved in this case were within the police power of the state and therefore constitutional.

The complainant's bill was therefore dismissed.—*Marsh v. Earle, Governor*, 24 F. Supp. 385.

Society Proceedings

COMING MEETINGS

- American Academy of Ophthalmology and Oto-Laryngology, Chicago, Oct. 8-13. Dr. William F. Wherry, 107 South 17th St., Omaha, Executive Secretary.
- American Clinical and Climatological Association, Saranac Lake, N. Y., Oct. 9-11. Dr. Francis M. Rackemann, 263 Beacon St., Boston, Secretary.
- American College of Surgeons, Philadelphia, Oct. 16-20. Dr. Frederic A. Besley, 40 East Erie St., Chicago, Secretary.
- American Public Health Association, Pittsburgh, Oct. 17-20. Dr. Reginald M. Atwater, 50 West 50th St., New York, Executive Secretary.
- American Roentgen Ray Society, Chicago, Sept. 19-22. Dr. Carleton B. Peirce, Royal Victoria Hospital, Montreal, Canada, Secretary.
- American Society of Anesthetists, New York, Oct. 12. Dr. Paul M. Wood, 745 Fifth Ave., New York, Secretary.
- Association of American Medical Colleges, Cincinnati, Oct. 23-25. Dr. Fred C. Zapffe, 5 South Wabash Ave., Chicago, Secretary.
- Central Association of Obstetricians and Gynecologists, Kansas City, Mo., Nov. 2-4. Dr. W. F. Mengert, University Hospitals, Iowa City, Secretary.
- Central Society for Clinical Research, Chicago, Nov. 3-4. Dr. L. D. Thompson, 4932 Maryland Ave., St. Louis, Secretary.
- Clinical Orthopaedic Society, Little Rock, Ark., and Oklahoma City, Oct. 13-14. Dr. H. Earle Conwell, 215 Medical Arts Bldg., Birmingham, Ala., Secretary.
- Colorado State Medical Society, Colorado Springs, Oct. 4-7. Mr. Harvey T. Sethman, 537 Republic Bldg., Denver, Executive Secretary.
- Delaware, Medical Society of, Wilmington, Oct. 9-11. Dr. John H. Mullin, 601 Delaware Ave., Wilmington, Secretary.
- Indiana State Medical Association, Fort Wayne, Oct. 10-12. Mr. Thomas A. Hendricks, 23 East Ohio St., Indianapolis, Executive Secretary.
- Inter-State Postgraduate Medical Association of North America, Chicago, Oct. 30-Nov. 3. Dr. W. B. Peck, 27 East Stephenson St., Freeport, Ill., Managing Director.

THE AMERICAN RHEUMATISM ASSOCIATION

Sixth Annual Meeting, held in St. Louis, May 15, 1939

DR. LORING T. SWAIM, Boston, Secretary

(Concluded from page 1066)

The Origin and Nature of Normal Synovial Fluid

DRS. MARIAN W. ROPES and WALTER BAUER, Boston: Many theories concerning the origin of synovial fluid have been proposed, the chief ones being secretion by the synovial membrane, degeneration of membrane rubbed off during motion, dialysis of blood plasma and formation as tissue fluid. No one theory has been generally accepted, however, because knowledge of the characteristics of normal joint fluid has been insufficient to prove the mode of formation. Extensive studies of simultaneously obtained arterial blood and normal joint fluid had been made. It was impossible to carry out such a complete study on the 1 or 2 cc. of fluid obtainable from a normal human joint, so the majority of the studies have been made on fluid from the astragalotibial joint of cattle. Normal human fluid obtained post mortem has been compared whenever possible.

Normal synovial fluid is a clear, pale yellow, viscous, relatively acellular liquid. The cytology varies somewhat in different species. In normal human fluid, which is most important for comparison with pathologic fluids, the average total cell count is 63 cells per cubic millimeter, with a differential count of 69 per cent mononuclear phagocytes, 24 per cent lymphocytes and only 7 per cent polymorphonuclears. The fluid count does not reflect changes in the blood count. Variations in the number of cells and the differential are found normally. That these variations are reactions to daily minor traumas is suggested by the fact that higher counts and higher percentages of phago-

cytes are found in cattle joints that show degenerative cartilage lesions than in the normal cattle joints. Further evidence is found in postmortem human fluids, which show the highest counts in joints with the greatest degenerative changes.

The specific gravity of 1.010 and total solids of 2 per cent correspond with those expected in a dialysate with low protein content. The osmotic pressure studies suggest one of the roles played by mucin in the joint. The observed osmotic pressure of the serum agrees well with the pressure calculated from the albumin and globulin content. In the case of the fluid, however, the pressure calculated from the albumin and globulin is only 57 mm. of water, in contrast to an observed value of 150. Mucin is the only other known colloid and, if the excess osmotic pressure is due to mucin, it is found to exert an osmotic pressure nine times that of albumin—indicating the importance of mucin in regulation of fluid exchange between blood and fluid.

Nonelectrolytes (nonprotein nitrogen, urea and uric acid), which are readily diffusible substances, are found in approximately equal concentration in fluid and plasma, as would be expected in a dialysate of plasma through a membrane permeable to these substances. The concentration of sugar, however, tends to be slightly lower in the fluid than in the plasma, presumably owing to the fact that complete equilibrium never exists in the case of sugar and partly to the rate of utilization. Electrolytes are distributed between plasma and fluid just as they would be between plasma and a dialysate containing the same protein concentration as joint fluid.

The distribution of electrolytes and nonelectrolytes is in accord with the theory that synovial fluid is a dialysate. Perfusion experiments have shown that the anatomic facts are in accord with this theory. The subsynovial blood supply is rich, and in many instances only a few layers of cells are found between the blood vessels and the joint cavity—an ideal arrangement for diffusion.

Formation of synovial fluid by dialysis satisfactorily explains its composition except for the presence of albumin, globulin and mucin. Fibrinogen is absent in normal fluid.

Albumin and globulin are found in normal fluid. The summation of evidence at present indicates that there is slight capillary permeability to proteins in joint fluid. The high albumin-globulin ratio indicates a greater permeability to the smaller molecule, albumin, than to the larger, globulin. The results of animal experiments carried out in our laboratory on the permeability of synovial membrane to proteins are in accord with the protein content in normal fluid.

The concentration of mucin in normal human fluid is approximately 0.8 per cent. It is this mucin which produces most of the viscosity and resulting lubricating value of the fluid. Removal of the mucin reduces the relative viscosity from high values of 50 or more to less than 2. As already indicated, studies of normal fluid suggest that mucin plays a role also in the exchange of water and other substances between blood and fluid. The origin of mucin remains obscure. Our studies to date suggest that it is formed (at least in part) by the connective tissue cells surrounding the joint.

The results of studies of normal fluid to date, therefore, indicate that synovial fluid is a clear, viscous, relatively acellular liquid which is a dialysate of blood plasma to which is added mucin as the fluid diffuses through the connective tissue surrounding the joint. With this information as a basis of comparison, we have already found that detailed analysis of pathologic effusions gives much more diagnostic information than has hitherto been thought possible.

DISCUSSION

DR. J. ALBERT KEY, St. Louis: This is the most careful and complete analysis of synovial fluid that we have had to date. I wonder whether the theory explains the presence in the joint of such small amounts of fluid. There is present in the joint a slightly negative pressure, and the amount of fluid which is present is just sufficient to lubricate the joint surfaces. As to the presence of mucin, I wonder whether any one has been able to obtain mucin from the connective tissues around joints. I know that most of us are familiar with the various attempts to demonstrate the secretory activity on the part of the synovial lining cells. It has been demonstrated from time to time that these cells contain globules of mucin, which are presumably ejected into the joint as occurs in the intestine. I myself have

never been able to demonstrate these globules. I have always considered the lining cells of the joints as lamellar connective tissue cells the only modification of which was one depending on the geographic situation and the mechanical forces that are brought to bear on them. It is important that Dr. Ropes and Dr. Bauer should either confirm or put at rest this theory to the effect that these cells are actually secretory cells similar to gland cells.

DR. M. HENRY DAWSON, New York: It is generally recognized that synovial fluid consists of two portions—one which appears to be a filtrate of the blood stream, and the other synovial mucin. It is concerning the nature and origin of this second constituent that there appears to be some difference of opinion. Last month, in association with Dr. Karl Meyer, I reported before the American Society for Clinical Investigation the isolation of an acid-polysaccharide which appeared to be responsible for the characteristic physical properties of synovial fluid. This acid polysaccharide occurs either free or united to protein in salt linkage only. It is our feeling that this constituent is probably elaborated by the lining cells of synovial membrane. Vaubel has shown that mucin is formed in tissue cultures of synovial cells; Kling has demonstrated so-called mucin granules in the lining cells and King has shown the presence of a Golgi apparatus in such cells. With regard to the other portion of synovial fluid, we agree that it is probably a filtrate of the blood stream. However, there is some doubt in our minds whether this can be proved by the methods which have been employed. Similar results have been obtained by studying the electrolytes in saliva and in bile, yet it cannot be stated that these fluids are filtrates of the blood stream. So also the immediate or close proximity of the capillaries and the synovial lining cells offers little evidence in support of the filtrate theory. The capillaries in the choroid plexus and the ciliary body are separated from spinal fluid and vitreous humor by only a single layer of cells, yet these fluids are almost certainly not simple filtrates. However, we do not wish to make too artificial a distinction between a filtrate and a secretion, for in all probability both processes come into play in the formation of synovial fluid.

DR. MARIAN W. ROPES, Boston: I cannot answer Dr. Key's question. Little is known concerning intra-articular pressure under varying conditions and the influence of such changes on the formation of synovial fluid. We have isolated mucin from synovial membrane, connective tissue obtained from the abdominal wall of rabbits, and from mucinous-like pleural adhesions from a patient with rheumatoid arthritis. All these mucins resemble synovial fluid mucin in their physical properties and in being destroyed by an enzyme which we have isolated from *B. welchii*. We have, as yet, no proof of their chemical identity but we hope to be able to show that these mucins are the same as synovial fluid mucin. We do not think that the chemical identity of any of the mucins has been proved. The exact formation of synovial fluid mucin is unknown. We have never been able to identify with any degree of assurance the mucin globules seen by others in the synovial membrane cells. We believe that the use of the word secretion is a play on words, because, whatever the mechanism of mucin formation is, cell activity is necessary. Whether it is similar to true secretion has never been proved. Surely it is not a glandular type of secretion. The mode of formation of serum proteins and the cells concerned have never been established. The process involved may be similar in the case of mucin. We also have isolated a polysaccharide such as Dr. Dawson has spoken of. The mode of combination with protein is not known. Some of the properties of mucin as it is normally found in synovial fluid resemble those of the compound of the polysaccharide with protein rather than those of the polysaccharide itself. I cannot answer the question about bile and saliva satisfactorily since I do not know the complete composition of electrolytes and nonelectrolytes. Knowledge of the concentration of a few constituents is not sufficient evidence to prove the mode of formation. Spinal fluid, for instance, was thought to be a dialysate until complete analyses had been made. Furthermore, the separation of fluid from plasma by only a few layers of cells is not of itself proof that the synovial fluid is formed by dialysis. Such an anatomic arrangement, however, is compatible with formation by dialysis.

Arthritis Associated with Lymphogranuloma Venereum

DRS. M. H. DAWSON and R. L. BOOTS, New York: During the past three years in the Arthritis Clinic of the Presbyterian Hospital we have observed twenty-four cases of arthritis exhibiting the following characteristics:

1. The arthritis pursues a variable course but it usually appears in a chronic, indolent, serous form showing a marked tendency to relapse. Intermittent hydrops of the joint is not uncommon. Occasionally, acutely swollen, painful and tender joints are observed.

2. The arthritis is usually polyarticular and may involve a variety of joints. It shows a predilection for the knees, ankles and wrists, and frequently the two knees or the two ankles are affected simultaneously.

3. The joint involvement may last for weeks or months, but in no instance is there evidence of bone or cartilage destruction. Except for periarticular swelling and effusion within the joint, x-ray examination fails to reveal any changes.

4. The character of the joint fluid shows considerable variation from case to case but it is never purulent.

5. Cultures of the synovial fluid on all ordinary bacteriologic mediums are sterile.

6. Finally, and most important of all, each case gives a definitely positive Frei reaction and the majority of cases show other evidence of infection with lymphogranuloma venereum.

It is realized that in advancing lymphogranuloma venereum as the causative factor of the arthritis in this group of patients other possible etiologic agents must be carefully ruled out. This has been done by every means at our disposal. In addition we feel that there is sufficient clinical evidence to consider this form of arthritis as a definite entity.

A number of experiments have been done in an effort to demonstrate both the virus and the Frei antigen in the synovial fluid. The results of these experiments are as yet inconclusive. At present therefore we simply wish to call attention to the fact that a rather characteristic form of arthritis is seen in certain cases of lymphogranuloma venereum.

DISCUSSION

DR. WARREN R. RAINEY, St. Louis: Three hundred patients with rectal stricture have been seen in the outpatient clinic at Washington University Medical School. All patients received antisyphilitic treatment until 1935. Throughout this period there was no clinical improvement. The joints chiefly concerned are the knees, wrists and ankles, although one patient has had a constant arthritis of the hip joint. The entire rectum and lower sigmoid of one patient were involved in a tubular stricture, and subsequently a pelvic abscess developed which at operation was found to be an abscess directly connected with the sigmoid. At all times when recurrences of acute symptoms occurred in this patient, the hip joint became acutely painful. In only one patient, that is the patient with arthritis of the hip, has there been any limitation of motion following the acute attack. The joints become slightly swollen and occasionally there is a small amount of fluid present. There is some heat and redness of the skin, but the acute inflammatory reaction as seen in the gonorrheal joint is absent. Aspiration of the fluid from the joint in one case gave a negative culture. It would be interesting to determine whether or not fluid removed from a joint could be properly prepared and used as a Frei antigen. A positive Frei test from such a source at the present time would be important in corroborating the opinion that the arthritis is secondary to the infection of lymphogranuloma venereum. It is difficult to say positively that arthritis is absolutely due to the lymphogranuloma venereum but it certainly is evident that the arthritis is most pronounced during the exacerbations of the colon and rectal manifestations of the disease. Fair responses occurred when the patients received antimony and potassium tartrate intravenously. Particularly the joint symptoms and the abdominal pains were relieved. Since sulfanilamide has been used, the responses to all acute symptoms have been most satisfactory; not only has the proctitis disappeared and the stricture softened, but the painful arthritis has been relieved within one week's treatment. We have not had sufficient time since the use of this drug to determine how long this relief will last but in certain cases there have been no recurrences of the arthritis or rectal symptoms for a period of three months.

Nothing characteristic is revealed by the x-ray examination, since bone changes are not pronounced. Here again a mild type of osteo-arthritis can hardly be called a secondary manifestation of lymphogranuloma venereum, since most of the patients have bad teeth, tonsillar infections and a history of both syphilis and gonorrhea. I am convinced that the arthritis seen during the recurrences of the acute manifestations of lymphogranuloma venereum and the acute period of the inguinal bubo certainly are secondary manifestations of this disease.

DR. CURRIER McEWEN, New York: At our clinic at Bellevue Hospital in the dermatologic and syphilologic services there were 186 patients in the past four years in whom a diagnosis of lymphogranuloma venereum was made; among these, three were listed as having had arthritic manifestations. The histories revealed the characteristics described by Drs. Dawson and Boots and Dr. Rainey. In one of the four surgical services there have been, in the past three years, fifty-four patients with rectal strictures of the type Dr. Rainey mentioned. Among these there were six patients who had joint manifestations. One of these probably had another form of arthritis but the other five fit in rather well with the picture described by Drs. Dawson and Boots. In two the arthritis was migratory with only mild objective changes; one was mono-articular and mild; two were more chronic, one lasting two months and one six months, but both healed without any residual joint changes, and they presented features described by Drs. Dawson and Boots and Dr. Rainey. Dr. Boris A. Kornblith of the Social Hygiene Division of the New York City Department of Health has recently analyzed 300 cases of lymphogranuloma venereum. He has told me that there were fifteen in which persistent migratory arthritis occurred lasting from one week to two months. Frei antigen was prepared from the joint fluid in one of our cases and was used to test patients known to have lymphogranuloma venereum. The tests were negative, like those of Drs. Dawson and Boots. I should like to ask whether any one knows whether these negative tests have any significance in suggesting that the arthritis is not due to lymphogranuloma venereum.

DR. ISADORE PILOR, Chicago: In 1932 I reported one of the first series of cases of lymphogranuloma venereum from the Cook County Hospital, Chicago. One case was complicated by erythema nodosum. There were definite pink nodules on the extremities, with vague arthritic pains. In that particular case we injected the antigen intradermally and at the same time injected a vaccine of hemolytic streptococcus and tuberculin to see if we could determine the usual causes of erythema nodosum. We obtained a striking reaction, reproducing a typical erythema nodosum nodule with the Frei antigen, with negative results to the hemolytic streptococcus and to the tuberculin. At that time we demonstrated the relationship of erythema nodosum to lymphogranuloma. It is not at all surprising to hear today that there are definite arthritic manifestations in this condition. However, I want to point out the frequency, particularly to those who may study the bacteriology of lymphogranuloma, of the secondary infection with staphylococcus, nonhemolytic streptococcus, and a large group of gram-negative organisms: that these secondary infections may act as a foci of infection and cause arthritic manifestations. There is another source of confusion in the Frei test which, like the tuberculin test, is permanent. The Frei antigen will remain positive for many years after apparent complete healing of the lesions.

DR. WALTER BAUER, Boston: Have the authors tried to make the Frei antigen from synovial membrane? From their description of the synovial fluid I think one could perform a biopsy with little danger of subsequent complications. We do such biopsies on our patients with rheumatoid arthritis and to date have not encountered any serious end results. We have seen only four cases of lymphogranuloma venereum with associated arthritis. They represented cases of acute arthritis coming on shortly after the buboes appeared.

DR. J. ALBERT KEY, St. Louis: It seems to me that the authors have adopted a typical laboratory attitude and left us to assume that they cure all these patients with no difficulty and that the treatment was relatively unimportant. I have seen three that resembled mild rheumatoid arthritis. We tried gold and, as I recall, it seemed to help the lymphogranuloma but did not do much for the arthritis. I wonder how Drs. Dawson and Boots get them well.

DR. M. HENRY DAWSON, New York: The observation which has been reported on erythema nodosum is interesting. I believe that Hellerström was one of the first to point out that erythema nodosum may occur as a manifestation of lymphogranuloma venereum. In regard to the treatment of this form of arthritis I do not think the situation is at all clear. The course of the disease is so variable that it is difficult to evaluate different forms of therapy. Some cases have apparently cleared up spontaneously in the course of a few weeks. Others have pursued a more chronic and intermittent course for months or even years. Some of these cases seem to have been influenced favorably by sulfanilamide and others by the administration of Frei antigen intravenously. However, we do not feel that we are as yet in a position to state which is the best form of therapy or even whether any form of therapy is really effective.

Rheumatoid Arthritis of the Spine

DRS. FRANCES BAKER, JAMES F. RINEHART, STACY R. METTIER and FRED S. BRUCKMAN, San Francisco: We have reviewed the histories of patients with rheumatoid arthritis of the spine seen in the Arthritis Clinic of the University of California-Hospital since September 1933. No single etiologic factor takes on importance. Eight patients gave a definite history of rheumatic fever and eight gave histories of definite injuries as the immediate cause of their primary symptoms. Laboratory studies are not particularly helpful. We are impressed again by the fact that rheumatoid spondylitis is largely a disease of males and that the age at which symptoms are noted is frequently between 16 and 20 years. We also found that of the seven patients, or 13.4 per cent, of our series who had a family history of arthritis five had spondylitis before the age of 20 years and six before 25. These facts make us feel that this disease might well be associated with an endocrine nervous disturbance not understood.

The history of one family is worthy of note: Eight paternal aunts and uncles of two patients had "rheumatism" of the spine resulting in crooked backs. The father died of rheumatic heart disease at the age of 40 years. Three sisters died in infancy. One brother had infantile paralysis. Four brothers and one sister developed arthritis.

Observations are presented on a series of patients with rheumatoid spondylitis, pertaining to their vitamin C nutrition and metabolism. The almost uniformly low plasma vitamin C levels and other data indicating significant undersaturation in these patients is considered to show clearly the existence of vitamin C deficiency in this disease. The conviction is expressed on the basis of these and other clinical observations that this deficiency contributes to the onset and continuance of the disease.

DISCUSSION

DR. RALPH H. BOOTS, New York: I do not think there is sufficient evidence to warrant calling this condition "rheumatoid arthritis of the spine," as the title appears on the program. For the present, one of the other terms by which this condition is known is preferable: infectious spondylitis, Marie-Strümpell arthritis or rheumatoid spondylitis. I should like to emphasize three points brought out in this paper. First, the sex incidence. Dr. T. Lloyd Tyson in our clinic at Presbyterian Hospital has recently collected statistics on approximately sixty cases; the sex incidence was four males to one female. I believe that the authors had nine males to one female. This is quite the reverse of the sex incidence in rheumatoid arthritis, in which the disease occurs in one male to approximately three females. Second, the age incidence of onset, which is about ten years younger than that of patients with rheumatoid arthritis. Third, the familial history as shown by the authors. Dr. Tyson found in his series a history of rheumatic fever or rheumatoid arthritis in some member of the family in 50 per cent of the cases. We also found that 6 per cent of the patients had evidence of rheumatic heart disease and 5 per cent had some psoriatic lesion. Did any of the authors' patients exhibit subcutaneous nodules or a high streptococcus agglutination titer, such as is found in rheumatoid arthritis? None of ours did. This work on vitamin C is interesting but it must be admitted today that the etiology of this form of arthritis is still unknown.

DR. J. ALBERT KEY, St. Louis: I object to calling this condition rheumatoid arthritis of the spine. The characteristic feature of rheumatoid arthritis as regards the bone is atrophy.

The characteristic of ankylosing spondylitis is the production of new bone; in other words, they are diametrically opposite in their effect on bone. Rheumatoid arthritis is primarily a disease of the synovial tissues with gradual destruction of the joint by invasion of the cartilage by inflammatory tissue. Any one who has ever operated on the hip in one of these cases knows that there may be a mass of bone as big as two fists around the acetabulum. The same is true of the spine. It strikes Dr. Ober and me as amazing that an individual living in California should be deficient in vitamin C. I am glad that the authors stated that it was due to a defect in the patient's metabolism. Patients with scurvy who develop subperiosteal hemorrhages may lay down bone beneath the periosteum when they improve. Now it is not beyond the realm of possibility that patients with ankylosing spondylitis may have intermittent scurvy which would cause hemorrhages beneath the periosteum and after each attack deposit a little more bone with ankylosis as the final result. These joints are ankylosed from without and the joints disappear later.

DR. WILLIAM K. ISHMAEL, Oklahoma City: I find it necessary frequently to testify before the local Labor Commission as regards the role of trauma in relation to the final disability. If there is a rule as to whether trauma is responsible, I should like to know.

DR. FRANK R. OBER, Boston: Do these patients who had a complete cessation of their spondylitis still have a deficiency in vitamin C, and when does the deficiency in vitamin C begin? Does it begin before they have the onset of spondylitis or during the attacks? What is the rate of vitamin C deficiency during the progress of the disease? A young woman who has spondylitis when she increases the vitamin C intake by a glass of orange juice a day gets into trouble with her joints in a few days. What is the relation here? Doesn't overstimulation of vitamin C cause the same symptoms as an underamount of vitamin C?

DR. LORING T. SWAIM, Boston: I have been studying 106 cases of Strümpell-Marie arthritis; twenty-three of the patients were women, about the same proportion that the authors spoke of. I also have a family that I have been watching in which the father, two sons and a daughter have Strümpell-Marie arthritis. I agree with Dr. Key that it does not seem like true rheumatoid arthritis in some cases. We have had autopsies in a few cases and the intervertebral disks are apparently perfectly intact, with ossification of the intervertebral ligaments and fusion of the articular facets. In my studies of vitamin C, deficiency is about the same as I find in rheumatoid cases. I do not feel that there was any more deficiency in vitamin C than in people comparably sick with rheumatoid arthritis.

DR. CURRIER McEWEN, New York: I should like to ask what the authors find the vitamin C levels to be in patients with debilitating diseases other than rheumatoid arthritis and spondylitis.

DR. M. HENRY DAWSON, New York: I have always been under the impression that the primary lesion in rheumatoid spondylitis was a synovitis of the posterior intervertebral joints and that the longitudinal ligaments and intervertebral disks were not involved until the later stages of the disease. I have always felt that the pathology of this condition was essentially the same as in rheumatoid arthritis of the extremities. According to ideas which have been expressed here today there seems to be some difference of opinion in this matter. If there are significant differences, I think it is time that they were adequately described.

DR. WALTER BAUER, Boston: I wish to agree with Dr. Dawson. The pathology of rheumatoid arthritis is the same whether it involves the spine or the peripheral joints. This is well shown in cases with associated hip joint involvement. I do not believe that vitamin C deficiency plays a major etiologic role in rheumatoid spondylitis. One might similarly argue that the deficiency of hemoglobin, serum proteins and serum cholesterol seen in patients with rheumatoid arthritis is also of etiologic significance. One should be extremely cautious in judging the effect of therapy in rheumatoid spondylitis. Certainly a period of two to three months is far too short a time to enable one to say that a patient with rheumatoid spondylitis has been benefited by the therapy employed.

DR. J. A. KEY, St. Louis: These patients have synovitis in the intervertebral joints but they get ankylosis by ossification of the joint capsule and ligaments. Bone grows out from the attachments around the joints and then the two bones gradually fuse.

DR. ROBERT B. OSGOOD, Boston: One does not always get calcification of the sacro-iliac joints. I have had a case under observation for eight years and the sacro-iliac joints are perfectly free; so it does not always start in the sacro-iliac joints.

DR. CURRIER McEWEN, New York: I believe that the information regarding the identity of pathologic changes in rheumatoid arthritis and the type of spondylitis we are discussing is too indefinite at present to warrant a final assumption that the entities are the same. On a clinical basis there are a number of such striking differences between the two that one must at least suspect they are different diseases. There is a striking difference in incidence between the two sexes. The serum of patients with rheumatoid arthritis agglutinates hemolytic streptococci in the great majority of cases, whereas that of patients with spondylitis ankylopoietica never does. Furthermore, in my limited experience with spondylitis, the patients having it have seldom had involvement of peripheral joints (other than the hips and shoulders) and in the few patients with involvement of other joints the changes have not been characteristic of rheumatoid arthritis. I am convinced that, if there is any doubt of spondylitis ankylopoietica being rheumatoid arthritis of the spine, it should be listed as a separate entity with the mental reservation of course that it may well be merely a form of rheumatoid arthritis. I do not see how considering the two identical as long as there is any reasonable doubt can add to scientific advancement; rather it adds to confusion and delays a satisfactory classification of these diseases.

DR. WALTER BAUER, Boston: In the thirty cases of rheumatoid spondylitis that we encountered in our first 300 patients with rheumatoid arthritis there were seventeen that had peripheral joint involvement. Some of these patients had multiple joint involvement. In only three cases was the disease confined to the spine alone. The remaining cases had involvement of the spine and shoulders or hips. I have never seen a rheumatoid arthritic nodule in a patient with a true rheumatoid spondylitis unless he had peripheral joint involvement. Hensch presents an illustration of one such case in his Nelson's Loose Leaf Surgery article. If we could occasionally demonstrate true rheumatoid arthritic nodules in cases of rheumatoid spondylitis without peripheral joint involvement, we would then be in an even better position to argue that rheumatoid spondylitis and the peripheral type of rheumatoid arthritis are one and the same disease.

DR. JAMES F. RINEHART, San Francisco: One can see shadows of increased density reaching between the vertebral bodies which represent calcification and possibly ossification of the ligaments. The vertebral bodies themselves, however, are demineralized and show no hypertrophic spurring. Many patients in this group have peripheral joint involvement at some time during the course of their illness, just as Dr. Bauer found in his series of cases. I agree with him that this is perhaps the strongest evidence that this type of spondylitis is fundamentally similar to the other forms of rheumatoid arthritis. It has already been pointed out that this is a proliferative synovitis in the small joints of the spine. Dr. McEwen has asked about the vitamin C levels in other debilitating diseases. I would emphasize the consistency of data presented here. Over 90 per cent of these afebrile patients with rheumatoid spondylitis had a severely lowered vitamin C concentration in the blood. We have studied quite a series of chronic infections unassociated with arthritis which have not been analyzed for this report. We found the values lowered in approximately 40 per cent of such cases, but they have not shown the uniformly and strikingly low levels seen in rheumatoid arthritis. I do believe that Dr. Boots seriously objects to the terminology. I can see no distinction in the terms "rheumatoid arthritis of the spine" and "rheumatoid spondylitis," which is the designation used by Dr. Boots's associate, Dr. Dawson. Dr. Ober asked if the deficiency in vitamin C exists before or after the onset of the disease. Naturally I cannot directly answer this question because we do not see patients before the onset of the arthritis. On the other hand, we have gone into the dietary history in cases

studied and find that many have been taking less than 10 mg. of vitamin C a day. The normal human requirement is estimated at approximately 50 mg. daily. If these patients take only 10 mg. a day, it would not be unusual if they suffered some degree of vitamin C deficiency after a period of years. Furthermore, we have also indicated that certain of these patients show faults in absorption or utilization of vitamin C which would further contribute to the deficiency.

Treatment of Chronic Arthritis: Results with Saline Injections Used as Controls for Vaccine Therapy

DRS. NATHAN SIDEL and MAURICE ABRAMS, Boston: This article is to be published in full in THE JOURNAL.

DISCUSSION

DR. RUSSELL L. CECIL, New York: Ten or fifteen years ago, vaccine therapy was widely used in arthritis clinics and was considered a valuable form of therapy. At present it seems to be on the wane and we are now in the era of gold therapy. I wonder what gold therapy will look like fifteen years from now. We must attempt to maintain an even keel and try to evaluate our therapy as we go along and not be carried too far one way or the other. The authors quoted me as saying that the majority of patients are benefited by vaccine, and that seems to have been their experience also. There is a great deal of difference, however, between benefit and cure. If we could cure 75 per cent of our cases with either vaccines or saline solution we would have a fine record. The trouble is that these therapies seem to help the patient temporarily but do not lead to real, permanent cures. When I see a rheumatoid patient cured with vaccine I wonder if my original diagnosis was correct. Our criteria for the diagnosis of rheumatoid arthritis should be more clearly defined. Certainly we should not put all cases which we cannot classify into this group. The rationale of vaccine therapy has not been settled any more than the rationale of gold therapy. I do think that foreign protein therapy has a place in the treatment of arthritis. I would just as soon give streptococcus vaccine as boiled milk or some other form of protein. So far as I have been able to observe, if streptococcus vaccine is given intravenously the immunizing effect seems to be practically nil and whatever effect there is must be a nonspecific one. One sees strange things happen in the therapy of osteo-arthritis. It is considered quite unorthodox to use vaccine in osteo-arthritis; but when I do not know what else to do for this condition, I am occasionally guilty of using vaccine in osteo-arthritis and, strangely enough, it sometimes does help. I think here we are probably dealing with a psychotherapeutic reaction. As for any rationale for vaccine treatment, I think we have always been on thin ice and probably will continue to be there.

DR. R. H. FREYBERG, Ann Arbor, Mich.: I have had relatively little experience with the use of vaccines, but to date I have not been impressed with their value as I have employed them. About a year and a half ago I visited many clinics and laboratories engaged in the study of arthritis. I made it a point to inquire at each place whether or not vaccine was used or advocated. From eleven such inquiries I learned that four used vaccines commonly and considered them valuable. Three of these four had developed different vaccines in their own laboratories. The manner of their use differed considerably. One of these four treated all types of chronic arthritis with a streptococcus vaccine. The other three treated only rheumatoid arthritis. Those who considered vaccines valuable were not sure how they acted to accomplish the benefit. Six other clinic heads had given up the use of vaccine after clinical trial, considering it valueless or of possible benefit only rarely. One other did not advocate vaccine therapy chiefly because he considered it on an unsound basis. This survey shows how different is the opinion concerning the value of vaccine therapy among our contemporaries. Certainly one must consider that streptococci play an important role in the etiology of arthritis if one considers streptococcus vaccine to be of direct therapeutic value. Moreover, one must believe that the administration of vaccine in some way aids the body in combating streptococcal infection or the abnormalities at the joint which in some way are thought to result from this infection. Objective proof that either of

these premises is true is to my knowledge lacking. If vaccine is used, should it be autogenous or stock vaccine, polyvalent, mixed; should it be injected intradermally, subcutaneously or intravenously; should small or large doses be used? If vaccine therapy is beneficial, does it act to increase specific immunity, desensitize or benefit in a nonspecific or indirect way? These are questions still not satisfactorily answered for me and answer for which must necessarily await elucidation of the cause of arthritis and a better understanding of at least immune response. An evaluation on the basis of clinical test requires careful control studies. Measuring change in the arthritic process is not as easy as measuring changes in blood following therapy for anemia, for instance. In considering clinical evaluation of the effect of vaccine, Drs. Sidel and Abrams have clearly shown how deceiving can be the apparent response to injected medications. In support of their study, I wish to mention a similar investigation by Drs. Dreyer, Singer and Pilot, noted in abstract in a recent program of the Central Society for Clinical Research, which indicates that "when normal sodium chloride was substituted for vaccine in a group of twenty cases of atrophic and fifteen of hypertrophic arthritis, all of whom had been responding favorably to the vaccine, there was no change in favorable response. Also a group of patients not previously treated with vaccine showed clinical improvement when saline injections were given without previous vaccine administration." They concluded that "hypodermic normal salt solution was as effective in the treatment of chronic arthritis as like quantities of a streptococcus vaccine." That the injection of medication can have a strong psychic effect cannot be doubted. The authors' investigation has extended over a sufficiently long time and includes a large enough group of cases to make the results surely significant. It clearly shows that it may be not the medication that is injected but the injection itself, with the opportunity therewith for the institution of other factors of treatment, that produce results which may often have been erroneously attributed to vaccine.

DR. IRVING DREYER, Chicago: Four years ago my associates and I commenced a study along the lines of the one just reported in a similar group of patients and with similar results. Our procedure was somewhat varied in that we tried to control treatment more intensively. In the first place we used vaccines that were giving a definite response; these were prepared from a definitely known and well studied bacterium—*Streptococcus haemolyticus* Davis—for which we had extensive bacteriologic data. This was a monovalent vaccine and the Crowe minimal dose method was used with subcutaneous injection. In patients who were getting streptococcus vaccine and in whom without notice we switched to saline solution we saw no change in the beneficial response in those who were responding favorably. In the group of patients who were not getting vaccine in whom we administered the saline solution the response given was about the same as in those who had been switched from vaccine to saline solution. Another method of control was to continue treatment for at least six months in order to eliminate meteorological effects. We observed some patients for four years. We tried omitting the saline solution in a few cases. In these cases aspiration of a few minims of air from an empty vaccine vial gave the patients no opportunity to notice a change in our procedure. We noted no change in our patients who were responding beneficially prior with vaccine. Finally the technic—subcutaneous injection—was identical in the vaccine and saline groups. One other point is the type of patient. Usually these were dispensary patients. However, to convince myself I introduced a little saline therapy among private patients who were responding well to vaccine. They too noted no difference. Among the problems that are brought up by this sort of study, the first and most important is this: Are the results of vaccine therapy to be explained solely on a psychologic basis? If so, may we use the term suggestion instead of psychic? And if so, who is being suggested, the patient or the doctor? Pavlov has shown that by repeated association with a secondary stimulation an organism can be conditioned against a certain type of response. Are we conditioning our patients to a favorable response by giving hypodermic injections to a group of individuals susceptible to mass suggestion? Next, are we altering the reactivity of the patient's cellular structure when we use vaccine and so desensitize him? If this is true then the reported

results with saline solution will have to be taken into consideration. Vaccine therapy has been reputed by some to be a form of immunization. This theory will have to be evaluated in the light of this investigation. Finally, is it possible that the mere prick of a needle will be sufficient to stimulate a beneficial response? Reports by Petersen and Levinson, by Reese and by Mueller indicate that minimal nonspecific stimulation to the skin can so disturb the balance of the autonomic nervous system that as a result changes in the distribution of the white blood cells, in the leukocyte partition and in the chemical constituents of the blood can occur. That profound autonomic disturbance can occur in sensitive individuals from puncturing the skin and subcutaneous tissues is common knowledge and is illustrated by the shock accompanying aspiration of a joint or by the introduction of a needle into the pleural space.

DR. K. K. SHERWOOD, Seattle: I have been using saline injections in arthritis for four years and appreciate the great difficulties that are encountered. I have used intravenous injections. From a laboratory standpoint I have determined that there is no shift in the Arneth count of the leukocytes following saline solution. The things I have learned in these four years are two: first that atrophic arthritis and hypertrophic arthritis are not uniform syndromes; in other words, in order to evaluate vaccine therapy it seems to me we have to subdivide our grouping further. There are some types of cases, such as spondylitis, which do not tend to improve under any therapy. There are other types which improve regardless of what is done. The second point which makes the control series difficult is the treatment of complications. These patients may be suffering from pyelitis, may have menopausal disease, may have constipation or obesity, and it is difficult to keep the patient from self medication or to withhold symptomatic medication, all of which may influence the results.

DR. FRANCIS J. SCULLY, Hot Springs, Ark.: I should like to ask the authors whether in giving the vaccine intravenously they had shock reactions or whether they gave it according to the method of Dr. Cecil without getting shock reaction. At the time at which foreign protein injections were first used I was associated with Dr. Joseph L. Miller and observed many cases of shock reaction. I have not used vaccines for this purpose in chronic arthritis since then, as the results observed were not good. I have used vaccines in selected cases of rheumatoid arthritis, giving it in the dose recommended by Dr. Cecil. I have not used it in osteo-arthritis. I gave it for its desensitizing value rather than for its immunizing value. There is no doubt of the psychologic value of any injection. If one did not get any more than just the psychologic effect to help keep up the patient's morale it is certainly of advantage to those suffering from chronic arthritis. I believe one is justified in using vaccines or other injections until a remission can occur or until other therapy such as baths and medication can have an effect. If one is going to give something as an injection I believe the vaccines would be better than the simple saline solution, as it would have the desensitizing value at least. The report of Drs. Sidel and Abrams of 84 per cent improvement with saline solution certainly seems better than the results we get in Hot Springs with the baths.

DR. L. MAXWELL LOCKIE, Buffalo: I should like to ask how the group of arthritic patients are coming along who receive no form of injection treatment.

DR. EPHRAIM GOLDFAIN, Oklahoma City: I began to use a combination of mixed polyvalent and autogenous bacterin. At the beginning, even though I used small doses, rather serious effects were produced in some of my cases, because even with the small doses they would get sustained and lasting adverse reactions that often caused a relapse in their joint symptoms and greater disability over a long period of time. Eventually I found that it was necessary to treat arthritic cases, especially the chronic infectious polyarthritis and atrophic type of arthritis, by means of doses of vaccine which are suited for the individual and are of such quantity as will cause a desensitization on the part of the patient toward the bacterin rather than the production of immunity. After adequate desensitization had been established, gradually increased dosage was possible in many cases. Vaccine therapy is a dangerous weapon. Its dosage must be adjusted to each individual. It must be used on a basis

of desensitization and not on a basis of establishing a solid immunity. In the bacterin treatment of chronic infectious arthritis or atrophic arthritis one should be careful that the amount of antigen introduced is so regulated that an unfavorable reaction will not occur when the antigen combines with the involved joint tissues, as it must in due time. I feel, therefore, that it is necessary for us to know whether these principles in respect to vaccine therapy of arthritis were observed in the cases quoted before this work and its stated results can be accepted.

DR. NATHAN SIDEL, Boston: I am interested in the figure of four years that has been mentioned by some. It is quite a coincidence. As to Dr. Dreyer's discussion as to why saline solution is of value, all the questions he has raised have been considered but I think they are speculative. I cannot add anything to them. As to Dr. Scully's comment on the reaction in two of his patients, there were no reactions with large doses in our patients. We followed the plan of Dr. Cecil and have not had a single reaction. The dose was worked up gradually. In answer to Dr. Lockie's question about those who did not have saline solution and how they got along, we have quite a number who did not get injections and they begged for them. We try to keep one group without injections, but they see so many others getting injections with beneficial results that they want injections. Dr. Goldfain mentioned using vaccines for desensitization. In view of our experience, I cannot see why vaccine should be used at all except as an adjunct to other therapy. If a patient is told to follow a certain program of therapy and certain hygienic measures, even the most intelligent will not do it unless something tangible is done. If a vaccine is given, I suppose that helps because the patient is under frequent observation and thus made to toe the mark a little bit more.

The Prevention of Arthritic Deformities by Early Orthopedic Management

DR. JOHN P. STUMP, New York: Operating on crippled arthritic patients makes the orthopedic surgeon keenly appreciate the necessity of preventing deformities and preserving normal structure and function of joints early in the disease. This desirable result can be obtained only if patients realize the necessity of prolonged, planned treatment and internists and orthopedists cooperate from the onset of arthritis until the patient is returned to useful activity.

Early orthopedic management corrects faulty body mechanics, saving patients the fatigue caused by unnecessary muscle strain. Correct alinement avoids stress on joint structures and renders them less vulnerable to advancement of arthritic processes.

Painful joints are relieved by rest in circular casts. Immobilization encourages subsidence of inflammation in joints and hastens return of complete motion. Immobilization should not exceed one week and must be vigilantly supervised.

Because arthritic patients rest long periods, firm beds are essential to prevent body distortions and soft tissue strain. A "cradle" prevents bedclothes from holding extremities in the flexed positions assumed during relaxation. Normal body relations should be maintained by correct, adequate splintage.

Following the acute stage, massage and active motion will encourage muscle development and joint motion. Ambulatory patients should have braces for joints incapable of self support. With weight bearing, arthritic patients are especially susceptible to distortions, and repeated orthopedic examinations are indispensable.

DISCUSSION

DR. K. K. SHERWOOD, Seattle: This paper emphasizes the fact that correct management of the arthritic patient involves not only the control of his pain and toxemia but also the prevention of his deformities. I am sorry that Dr. Stump has not laid more emphasis on the differentiation between the two different types of arthritis. Obviously the hypertrophic arthritic joint can be treated much more liberally than the atrophic. In atrophic arthritis of the slow progressive type, flexion deformity should be regarded as the natural outcome of the disease. In hypertrophic arthritis it usually appears only after gross neglect of the traumatic factors involved in the syndrome. I wish to modify Dr. Stump's statement about the dangers of the most comfortable position. The most comfortable posi-

tion is the one in which greatest support is given the joint. With the use of home appliances, such as pillows, partial flexion of the joint is a usual necessity in order to obtain support at the side of the joint. With casts, braces, and so on, the same support both longitudinal and lateral can be given in positions other than partial flexion. Thus, the development of deformities in arthritis is not simply a matter of incorrect application of support but more frequently of the incorrect type of support. Naturally, if proper support is correctly applied, no deformity will result. I wish to reemphasize the value of passive motion with rest in casts in the treatment of acutely involved joints. By this method, not only do we apply the correct support to the afflicted joint but ordinary nursing personnel can give passive motion at frequent intervals, thereby not only preventing ankylosis but hastening recovery. Finally, I have a question to ask Dr. Stump. I have found no satisfactory method of treating the subluxations of the fingers after they have occurred in atrophic arthritis. I should like to ask him what type of apparatus or plan of procedure he has found most satisfactory.

DR. EDWARD F. HARTUNG, New York: From my observation of the frequency with which deformities in arthritis are allowed to develop, these basic principles of prevention cannot be reiterated too frequently. Two important sidelights to this paper should be emphasized. If, as the recent U. S. Public Health Service Survey suggests, there are six million people today totally disabled because of rheumatism, it is obvious this large group of patients is mostly in the hands of the family doctor. My own observation is that our present medical school education gives scant attention to instruction in the fundamentals of medical orthopedics. Until this situation is changed and medical men know and care more about body mechanics, we shall continue to have a high incidence of deformities due to arthritis. My other thought is that such meticulous care to prevent deformities is usually not possible except in a hospital. As has been asked time and time again, where are the hospital beds for these patients, as well as for those of later stages who need orthopedic rehabilitation? These procedures may take from three months to two years or more. We have heard enough about the almost total lack of these facilities; now at last we may have action. Let us hope that the committee which Dr. Pemberton, I believe, is heading will produce a feasible plan quickly. With government agencies becoming increasingly more interested in this problem, we must not be found lacking a program.

DR. ROBERT B. OSGOOD, Boston: It is much easier to prevent than to cure these deformities. I have always maintained that arthritis is a medical disease. I have been waiting to have the medical man turn out to be an orthopedist. I do not see why an orthopedic man cannot take a medical course and why some medical men do not take orthopedic courses.

DR. LORING T. SWAIM, Boston: I believe that a great many more orthopedic men should immobilize joints. I have been doing it for ten years and I have not seen any joint that has been harmed, provided immobilization is supervised and done properly and with real gentleness. I have to use persuasion rather than violence. I think the picture Dr. Stump showed of the joint that relaxed in four days with rest was interesting and characteristic. A skin tight plaster should be put on, for even slight motion will cause irritation of the joint.

DR. JOHN P. STUMP, New York: I agree completely with Dr. Sherwood that in this paper differential diagnosis should have been considered, but in the effort to summarize the subject time did not permit completeness. It might have been better to limit the presentation to the prevention of deformities in rheumatoid arthritis. Dr. Sherwood brought out a point about the comfortable position being a position of support and mentioned the use of various braces; in this regard I consider that plaster of paris is a "home remedy." Dr. Hartung's point about six million arthritic patients is well made. Probably there are not enough orthopedists to care for them. However, effort on the part of internists and especially on the part of general practitioners to have some basic knowledge of orthopedic principles would enable them to do a great deal to prevent the deformities that the patient usually has by the time he reaches the arthritis specialist.

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1929 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

American Journal of Cancer, New York

36:343-526 (July) 1939. Partial Index

- *Argentaffine Tumors: Report of Eighty-Four Cases, Three with Metastases. J. E. Porter and C. S. Whelan, Boston.—p. 343.
Effects Induced in Pregnant Rats by Injection of Chemically Pure Carcinogenic Agents. J. M. Wolfe and W. R. Bryan.—p. 359.
Lymphosarcoma in Rats. C. S. McEuen, Montreal.—p. 383.
Cytology of Tumor Cell in Rous Chicken Sarcoma. M. Levine, New York.—p. 386.
Genetics of Nonepithelial Tumor Formation in Mice. C. C. Little, Bar Harbor, Maine; W. S. Murray, Buffalo, and A. M. Cloudman, Bar Harbor, Maine.—p. 431.
Effect of Ascorbic Acid on Hemorrhage Produced by Bacterial Filtrate in Transplanted Tumors. H. B. Andervont, Washington, D. C., and M. B. Shimkin, Boston.—p. 451.

Argentaffine Tumors.—Porter and Whelan reviewed the pathologic material at the Boston City Hospital from 1910 to 1937 and found seventy-two argentaffinomas of the appendix in a group of 26,384 appendixes removed surgically. Also there were seen two argentaffine tumors of the stomach, one of the gallbladder, one of the duodenum and eight of the small intestine. None of the appendical tumors were malignant but of the eight argentaffinomas of the small intestine three were malignant, of which two were found at necropsy and one was removed at operation. The stomach, gallbladder and duodenal cases were all benign. However, all argentaffinomas are potentially malignant. Their grade of malignancy as a rule is low. Treatment is surgical. The function of the argentaffine cell is not known; its origin is probably from the endoderm. It is suggested that argentaffinomas found in obliterated appendixes may be the result of proliferation of the argentaffine cells following chronic inflammation, while the tumors of extra-appendical origin are true neoplasms.

American Journal of Diseases of Children, Chicago

58:1-236 (July) 1939

- The Newborn: President's Address. C. G. Grulee, Evanston, Ill.—p. 1.
Diagnosis of Congenital Cardiac Defects in Infancy: Study of Thirty-Two Cases with Necropsies. Rachel Ash, I. J. Wolman and R. S. Bromer, Philadelphia.—p. 8.

Prevention of Nutritional Anemia.—Wilbar describes a new type of carbohydrate for the prevention and treatment of nutritional anemia in infants. It is made from sugar cane, contains considerable amounts of iron and copper and tends to

prevent nutritional anemia. A mean value for hemoglobin of 62 per cent (9.8 Gm.) and a mean red cell count of 3,700,000 were found in a study of 242 plantation children of Hawaii examined in 1936. Children of better economic levels showed hemoglobin levels and red cell counts approximating the normal. After a year's use of the new type of carbohydrate, 168 children from 3 days to 3 years of age showed a mean value for hemoglobin of 74 per cent (11.8 Gm.). The following year the mean value for hemoglobin of 171 children in this age group was 80 per cent (12.6 Gm.). The group mainly affected by the new carbohydrate, the infants less than 1 year of age, showed an increase in hemoglobin after using the new type of syrup from 59 per cent (9.3 Gm.) to 74 per cent (11.7 Gm.) to 79 per cent (12.5 Gm.). Seventy-four children less than 3 years of age in the control group who received no supplementary iron still showed anemia after two years, with a mean value for hemoglobin of 57 per cent (9 Gm.). Chemical analyses show from 1 to 3 mg. of iron per hundred cubic centimeters of cane syrup. This iron is all soluble and nearly all in the ferrous state, so that all of it should be available to the body. The amount of copper present in the cane syrup is approximately 0.2 mg. per hundred grams. The amount of iron and copper present in the syrup plus that in the milk approximates the figures given by investigators for the required iron intake for infants and the copper is sufficient to catalyze iron for the formation of hemoglobin. It is suggested that iron as a preventive of nutritional anemia among infants should be given in the form of a readily available food rather than in the form of a medication.

Blood Counts and Sedimentation Rates of Healthy Children.—Osgood and his colleagues give the total, differential and absolute leukocyte counts and sedimentation rates for healthy children from 4 to 7 years of age. As in similar studies the range which will include about plus or minus three probable errors, or 95 per cent, of healthy persons is given. The differential and absolute cell counts show a higher proportion of lymphocytes (from 1,500 to 8,500) and a lower proportion of neutrophil lobocytes (from 1,500 to 7,500) (polymorphonuclears) than have usually been given. The probable explanation for this is that most of the data previously reported have not been obtained on strictly healthy persons. The percentages of lymphocytes (20 to 70) and neutrophils (16 to 60) are the same as for children from 8 to 14 years of age, but the percentage of lymphocytes is higher and the percentage of neutrophils lower than for adolescents or adults. The percentage of eosinophils (0 to 8) is slightly higher than for adolescents or adults. The percentage of monocytes (0 to 7) is slightly lower than for adolescents or adults. The sedimentation rates form a skew curve, with the greatest number of determinations falling in the lower levels. It is probable that the rate of 15 mm. in forty-five minutes, which includes 80 per cent of the results, represents the strict upper limits of normal and that the higher rates are due to mild chronic infection of the tonsils, teeth or sinuses not detectable in routine physical examination.

Blood Pressure in Children.—Robinow and his co-workers tried to ascertain the proper width of the cuff for infants and children, to evaluate the factors which determine it and to establish standards for normal blood pressure during infancy and childhood. Their results are based on a study of infants and children, both white and Negro, between the ages of 6 weeks and 13 years. The authors find that it is convenient for clinical work to have a small number of cuffs and they suggest the use of three cuffs, measuring 2.5, 5 and 9 cm., respectively. The 2.5 cm. cuff was used in determining the systolic pressure of twenty-two newborn infants. The 5 cm. cuff was used for twelve children less than 1 year of age and the 9 cm. cuff was used for a group of thirty-four children from 1 to 13 years of age. Arterial blood pressures of children were recorded directly by means of the hypodermic manometer and compared with values obtained by the usual clinical methods. Systolic pressure was determined accurately by ordinary clinical procedures when the proper width cuff was used. Diastolic pressure by clinical methods is much less accurate in the case of children. The proper width of the cuff increases with the circumference and with the length of the arm and probably decreases with the compressibility of the arm. All three factors

vary in such a manner that the proper width of the cuff increases with age. Occlusion of an artery raises the systolic and the pulse pressure in the artery immediately above the occlusion. The changes are usually less pronounced in pulses of central contour. The contours of pulses in young children and infants are more central than in older children and adults. Blood pressure increases less with age than is commonly stated. Blood pressure is slightly increased by moderate excitement. Crying, coughing, retching and straining may increase the blood pressure as much as 60 mm. of mercury by raising the intrathoracic pressure. During cyclopropane anesthesia a slight rise of blood pressure was observed in most cases. In a single case marked transient hypertension was observed.

Behavior and Intelligence Quotients of Children.—Wile and Davis studied the problems of 100 children with intelligence quotients between 120 and 148, and 100 children with intelligence quotients between 50 and 79. Their data may not be wholly characteristic of all children in the same intelligence quotient categories, as their omission of children below the moron level limits deduction concerning mentally defective children as a group. In the superior group infantilism, regressive emotional social behavior and hypochondriac tendencies are much more marked, while in the inferior group disturbing behavior in the home, school maladjustment and intersibling conflicts are the more important problems. The authors draw no specific conclusions from the data presented save to emphasize that both superior and inferior children are exceptional children. Both should be studied in terms of their deviations from physical, intellectual, emotional and social norms. The problems and difficulties of the superior group are not less numerous than those of the inferior group. There is a major distinction in the more ready social adjustability of the superior group that promises a later socio-economic independence. A greater personality threat to the superior group is indicated. Problems of superior and inferior children arise from social-genetic factors and the children reflect their biologic and social origins. Both groups are social challenges which can be met only by diversified forms of educational, vocational and spiritual guidance.

Acute Appendicitis and Peritonitis.—The management of ninety-eight patients in whom spreading peritonitis developed as a complication of acute perforative appendicitis is discussed by Bower and his collaborators. Of these patients, 90 per cent received one or more laxatives. For this reason the term "laxative-induced spreading peritonitis" is used. The authors find that laxative-induced spreading peritonitis is more virulent than spreading peritonitis not so induced. Laxatives, their dose, number and kind, influence the mortality. The factors influencing the mortality of a spreading peritonitis beyond the control of the surgeon are age, delay in hospitalization, laxatives, complications, morphine preoperatively, enemas before admission, abdominal palpation and the application of ice bags, hot water bottles or poultices. Factors which influence the mortality of spreading peritonitis controllable by the surgeon are correct diagnosis, the evaluation of the immunologic response, when to operate, type of anesthesia, what is done at operation, what is done if the patient is not operated on immediately and what is done if the patient has been operated on immediately. During the last two years the authors have used the concentrated perfringens antitoxin, the 20 cc. syringe containing 10,000 units each of perfringens and vibron septique antitoxin with an excess estimated to be 30 per cent or more. Patients with serosa intact appendixes and those with localized abscess were not given the antitoxin; only those with spreading processes following perforation were treated. In none of the forty-six patients who received perfringens antitoxin as a part of the treatment for localization before operation did delirium develop. However, it occurred in one instance postoperatively, in a patient who on admission had a urea nitrogen of 50 and later uremia. Patients (fifty-two) who were operated on and then given the antitoxin suffered not uncommonly from mental irritability and delirium. Nausea and vomiting were rare in those given perfringens before operation but frequent in those operated on immediately. The mortality of the forty-six patients was 6.52 and of the fifty-two it was 15.39 per cent. Perfringens antitoxin promotes an early return of intestinal tone. The authors have repeatedly observed patients who, following its administration, have had bowel movements on the third day, and frequently diarrhea. It may be that the reaction of the mucosa of the intestine to the antitoxin is similar to the reaction of the epidermis when an urticaria develops; the resulting congestive edema involving the mucosa may stimulate peristalsis and cause spontaneous evacuation. The ninety-eight patients in this group were admitted to the hospital on an average of ninety-three hours after onset of symptoms, during which time they could not retain fluids. They were seriously ill but were in what might be called "the compensatory stage," "compensating" because the liver was supplying the circulating cell with nourishment in the form of glycogen. There is one function of the liver which, if utilized to the utmost during the compensatory stage, will avert disaster. It has been proved experimentally that the liver of both man and dog can metabolize approximately 1 Gm. of dextrose hourly per kilogram of body

weight. In the "compensatory" stage of spreading peritonitis the temperature is elevated, metabolism is increased and consumption of glycogen is increased over the normal. The liver can be supplied with this necessary amount of fuel by a continuous intravenous injection of 5 per cent dextrose solution, administered thirty drops to the minute; this will supply 2,700 cc. of fluid in twenty-four hours. This amount of fluid is sufficient to maintain water balance but will supply only 135 Gm. of dextrose, which, when metabolized, amounts to approximately 540 calories. An attempt should be made to maintain metabolic as well as water balance. If a patient in the "immunity developing stage" of spreading peritonitis reacts satisfactorily when given one tenth of what the liver can dispose of in the form of dextrose, he should react very much more satisfactorily with from one fifth to one third of what the liver can dispose of. A continuous intravenous injection of 10 per cent dextrose solution will supply the needs of the patient more adequately. The authors use this in a routine manner during the early stages of the disease, diminishing the percentage of dextrose when sugar appears in the urine.

Operative Treatment of Scoliosis.—Ullrich states that the objective in the treatment of scoliosis should be to correct the curvature completely and to maintain this correction permanently. That many curvatures can be completely corrected cannot be denied; indeed, in some, lateral bending alone is sufficient to do this. Correction or correction and compensation are best maintained, the author believes, by operative fusion of a portion of the spine. After complete physical and x-ray check-up, the patient should have exercises to improve posture, increase flexibility of the spine and keep him in close touch with the clinic. This is often continued because of delay in securing operative permission. The patients that are suitable candidates for correction, or correction and compensation, followed by operative fusion of the spine are divided into four groups: (1) those with mild or very flexible progressing curves that can be completely corrected, (2) those with moderate curves in whom partial correction is sought, as well as the reestablishment of body balance, (3) those with severe deformity, together with marked displacement of the trunk, in whom appreciable correction of the primary curve is not the sole object, but rather the reestablishment of body balance, and (4) those with undue pain or fatigue, regardless of the mildness or severity of the deformity, even if the growth period has passed. The patients in the first group are advised to have this treatment, especially when further growth is expected, because it is known that to let such a curve go untreated would result in the development of structural changes in the thorax and vertebral bodies, and as time goes on the possibility of complete correction would be proportionately lessened. On the other hand, to advise such treatment on a young or immature curve, the ends of which are not definite and the primary curve uncertain, would be equally dangerous. To correct and fuse a compensatory curve would leave an imbalance in the primary curve, and the patient would have been far better off untreated. The patients in the second group comprise probably the largest number of candidates for operative treatment. They consist for the most part of pre-adolescents whose deformity has been observed recently and who have been sent for advice and treatment. Some have curves in the lumbar spine that can be completely corrected, but the primary curve is higher in most. But if a moderate deformity can be corrected to a point below which the deformity is apparent, and at the same time whatever displacement there is be completely corrected, a good clinical result should be expected. When a patient is encountered with a severe rigid curvature with its attendant structural changes in the vertebral column and thorax, as well as poor vital capacity and lowered general health, he should be told that little or no correction of the curve itself will result but that body balance will be reestablished which will greatly improve the general health and make the treatment worth while. Often patients come in complaining of a painful area of the spine and subsequent examination reveals the presence of scoliosis. Such patients often do not have deformities sufficiently severe to warrant a long period of treatment. Exercises and massage should be begun and, if these are not successful, fusion of the painful area is advised. Since the time in bed is not much longer, they are put through the regular correction treatment.

Local Treatment of Snake Bite.—On the basis of experiments evaluating the local treatment of venomous bites, Allen states that an occlusive tourniquet can be employed successfully for the treatment of poisoning with strychnine and presumably other substances which are rapidly absorbed and disposed of, but that it is wholly harmful in the management of snake bite and its use should be abandoned. Because of local diffusion and binding of venom the earliest possible excision of a large area of tissue, somewhat as in a radical carbuncle operation, offers hope of benefit. In still more desperate cases, amputation is a more positive remedy. Local refrigeration is of no practical value, unless sometimes as an anesthetic. It multiplies the time during which circulation and absorption can be arrested and inhibits the local destructive action of venom, which is the chief disadvantage of the tourniquet method. Failure to save life under these conditions condemns the tourniquet theory. However, the tourniquet may be sometimes serviceable with or without refrigeration as preliminary to a delayed amputation. Since serum treatment is unavailable or delayed in the majority of snake bite cases, it is important that the effectiveness of mechanical methods such as the Jackson plan and the foregoing procedures be more adequately studied and taught. With the proper use of such methods, it seems possible that the mortality from all kinds of venomous bites may be almost abolished.

Estrogen for Involutional Melancholia.—Dynes gave large doses of estradiol benzoate, intramuscularly, to seven patients with involutional melancholia. The physiologic activity of the estrogen was determined by examination of the vaginal smear, determination of the pH of the vaginal secretion and observation of the staining response of the vaginal mucosa to compound solution of iodine. The patient's improvement or failure to improve was correlated with the changes indicated by these three tests. Except in two cases clinical improvement was definitely correlated with demonstrated effectiveness of the estrogen. The lessening and abolition of the acute agitation and tension occurred from two to five weeks after the beginning of estrogenic therapy. Failure of this therapy in the two cases was attributed to irreversible physiologic changes. No criteria,

either physical or mental, foretell with certainty what benefit will result from estrogenic therapy. However, every patient presenting definite evidence of involutional melancholia should be given an adequate therapeutic trial of estrogen.

Combined Oral and Subcutaneous Treatment for Ragweed Pollinosis.—The favorable results in ragweed pollinosis that others obtained by the oral administration of ragweed extract led London to believe that subcutaneous therapy could be enhanced by coincidental oral administration. Combined oral and subcutaneous therapy was tried on twenty-three patients in 1938 who in the previous year were treated by subcutaneous therapy alone. The combined treatment was also given to nineteen patients who had not been treated the previous year. The schedule of progressively increasing quantities of extract injected was maintained in all cases, the factor of oral administration being ignored. Oral therapy was begun during the last week in July and continued until mid August. The initial dose was 2 minims (0.12 cc.) of a 5 per cent extract of mixed ragweed, well diluted with water and administered three times a day after meals. The dose was raised by 2 minims twice a week. Constitutional reactions were exceedingly few and no more than for patients treated subcutaneously alone. Ten of the twenty-three patients given the combined therapy in 1938 fared better on combined treatment than on subcutaneous treatment alone. The improvement ranged from 10 to 45 per cent. Eight patients did not do as well and five reported no difference. Results for patients on combined treatment in 1938 do not differ significantly from the results for patients on subcutaneous therapy alone in 1937. Results for all treated patients with combined therapy are not better than the results the author is accustomed to expect from subcutaneous therapy alone. Considering the per-

sonal equation and variable factors involved, it would appear that, on the whole, combined therapy has added little to the orthodox subcutaneous therapy as far as improvement is concerned. Experimental work has shown that absorption of ragweed pollen extract from the intestinal tract, if at all, must be exceedingly small.

Reactions to Slow Epinephrine.—Cohn reports four cases in which slow epinephrine in peanut oil was used with the unusual symptoms of nausea, vomiting, chills, vesicular urticaria, cyanosis, increased dyspnea and swelling and edema of the forearm. Therefore epinephrine in peanut oil is not without its dangers and should not be given promiscuously. It should be used cautiously because of a possible underlying hypersensitivity to peanut oil as well as side effects the nature of which is not as yet understood.

Faradic Shock Treatment of "Functional" Psychoses.—Since complications such as dislocations and fractures occur in insulin and metrazol shock therapy and because of the terror and apprehension of the patient toward the treatment, Berkwitz offers faradic shock as a probable substitute. He tried this form of treatment in four cases of "functional psychoses" with encouraging results. Because of the small number of cases treated and the short period of time for observations, no definite conclusions are formed. It may be possible that this method may be an adequate substitute for the more drastic forms of shock therapy being used today. Further work is being done in this study. A simple apparatus was devised for the production of a faradic current. The source of the high potential current used for stimulation was a model T Ford spark coil; a six-volt dry cell battery of the A type was used to energize the spark (induction) coil. A resistance of 500,000 ohms (wire wound) was used in series with the secondary winding of the induction coil to reduce the milliamperage of the current used. The maximal voltage produced was approximately 20,000 volts. One electrode was placed on the forehead and the other on the nape of the neck. The patient's breakfast is withheld and an enema is given before the commencement of the treatment. From five to ten shocks of one second's duration each are given with an interval of one second between shocks. Such current can be safely tolerated by patients having no vascular disease. The patient's eyelids and facial muscles twitch, the head jerks, and evidence of fear and pain is exhibited. The patient does not appear to be in mental anguish or to have the violent jerking as is seen in convulsions. Immediately after the electrical shocks are given, from 4 to 7 cc. of a 5 per cent solution of pentothal sodium is injected intravenously to produce prompt sleep. Surgical anesthesia is attained in about thirty seconds. Unconsciousness lasts for several minutes, depending on the amount of the drug administered. Respiration must be watched closely. By the administration of an inhalant such as spirit of ammonia, the patient may be kept awake. Thus the interviewer often may gain much information of the content of the patient's thought which is not obtainable at other times.

Antibacterial Action of Arsenic, Sulfur and Nitro Compounds.—Rosenthal and his colleagues investigated the antibacterial power of compounds structurally similar to some active sulfur compounds but differing in that the sulfur was replaced by trivalent or pentavalent arsenic. The asymmetrical 4-nitro-4'-aminodiphenylarsinic acid and corresponding arsyloxide and arsine were active against streptococcal infections in mice. Acetylation increased activity and lowered toxicity but the effective doses were close to the toxic doses. The symmetrical 4,4'-diaminodiphenylarsinic acid and arsyloxide were inactive. 4-nitrobenzoic acid, the aldehyde, 4-nitrobenzal bromide, 4-nitrobenzyl chloride and 4-nitrotoluene possessed some activity, particularly against pneumococcal infections in mice. The various reduction products of 4-nitrobenzoic acid were inactive, as were likewise the symmetrical and asymmetrical benzophenones and benzhydrols and a series of other nitro and nitroso compounds. Acetylation of 4-nitro-4'-aminodiphenyl-sulfone decreased its toxicity without decreasing its antistreptococcal activity.

Alimentary Filling Defects.—Hubeny points out that the x-ray method of examining the gastrointestinal tract enables one to appreciate not only organic changes but indirect signs. The gallbladder, the liver, the pancreas and the stomach are

embryologically, anatomically, physiologically and pathologically closely related and should be considered as one physiologic system. Because of the continuity and contiguity of these numerous structures it is quite necessary to recognize filling defects as of pathologic and nonpathologic significance. The filling defect is the basic x-ray sign of morbidity. Errors in technic are responsible for some apparent defects. Among the most frequent is the neglect of eliminating pressure of the spine on the gastric shadow because of failure to elevate the chest and hips of the patient. The genuineness of a filling defect is portrayed by its persistence under all conditions during fluoroscopic examination, its unaltered position and contour after massage, its constancy on all roentgenograms and successive examinations and the lack of obliteration after the administration of antispasmodics. The permanence and actuality of a filling defect cannot always be determined by taking only a few roentgenograms. The filling defect may correspond to a palpable mass, for in occasional instances tumor masses that elude detection at the physical examination are felt by the roentgenologist. Unevenness of outline and lack of symmetry are rather constant in true filling defects. Abdominal rigidity and tension, pressure of a deformed costal arch, ascites, ovarian cyst or pregnancy may produce irregularities in the outline of the alimentary canal. Faulty mediums in which the barium is not evenly distributed may be misleading. Gas in the colon or fecal matter in the adjacent intestine also may cause indentations; however, palpatory shifting will help to identify these. Abnormal ligaments, peritoneal adhesions or membranes may produce filling defects. Commencing at the mouth, the first defect noticeable may be the esophageal indentation produced by the aortic arch, which is liable to be accentuated by the presence of aneurysm. The next irregularity is produced by the anatomic relation of the esophageal opening in the fornix of the stomach, accentuated or moderated by the angle of entrance. Sometimes the diaphragm produces an irregularity which is caused by the apposition of the cardia and the muscular interdigitations of the diaphragm. This has been noted especially in cases in which tight corsets have been worn. The spleen is the next offender, the shadow produced being quite characteristic. A physiologic kyphotic or lordotic spine may simulate defects. The gastric shadow is sometimes affected by the pressure of the transverse colon or a filled hepatic flexure which may impinge on the pyloric region. In some instances the gallbladder, either pathologic or nonpathologic, but especially the former, may subtract from the area of the pyloric region, particularly along the greater curvature. The third portion of the duodenum may show irregularities as it passes over the spine. It often happens that a concentric arrangement of portions of the jejunum or ileum, especially the latter, will cause apparent filling defects of the adjacent intestine, especially misleading when a non-visualized mass is contained in the lumen of the intestine. The foregoing conditions typify the usual probable sources of confusion, which can readily be recognized if anticipated. Among some of the pathologic conditions which produce filling defects are carcinoma, lymphosarcoma, splenomyelogenous leukemia, splenic leukemia, syphilis, varicosities, adhesions and benign tumors such as uterine fibroids and ovarian cysts. The history, physical examinations, laboratory observations, clinical and anatomic diagnosis and the work-ups of twenty-one cases are presented.

X-Ray Evidence of Tuberculosis.—Baker and Marquis emphasize the unexpected finding of tuberculosis in a large number of supposedly well people who had, immediately preceding an x-ray examination, passed a satisfactory physical examination. Instances are cited in which people have lost little or no time from work for years and yet were, by chance, found to be suffering from tuberculosis of one or both lungs, with cavitation and markedly positive sputum. Of a group of healthy male factory workers, examined only because they were about to be transferred to work known to be hazardous, 6 per cent were found to show pulmonary signs of sufficient gravity to prohibit the transfer. The authors believe it probable that more than 1 per cent of their readers, although considering themselves well, would be discovered to have either tuberculosis

or some other serious pulmonary lesion if they submitted to an x-ray examination. They arrive at this opinion after a study of the records of the Prudential Insurance Company and their own observations since Sept. 1, 1934. Even those who feel well should be urged to submit occasionally to an x-ray examination of the lungs. This becomes more urgently necessary if a person has frequent colds or feels tired to an unusual degree without known cause. The general practitioner can do more in this matter than the specialist, for he is ordinarily the first one to see the patient.

Carcinoma of Breast.—According to Simmons and his associates, from five to eight year cures were obtained in 70 per cent of sixty cases in which the carcinoma was confined to the breast and in 31 per cent of the 114 cases in which the axillary nodes were involved. The improvement in curability, as compared with previous series, may be attributed to standardization of the radical operation and to better selection of cases. Some improvement may be due to shortening of the preoperative duration of the disease as a result of educational programs. Radiation therapy was not employed in the present series. Clinical appraisal of axillary lymph node involvement is highly fallible. Nodes may be involved in nearly half of the cases in which no nodes can be felt clinically, and in half of the cases in which exploration of the primary tumor in the breast is necessary to establish the diagnosis of carcinoma. In high grade malignant carcinomas the tendency is to metastasize earlier and there is a markedly lessened chance of cure by radical operation. The age of the patient is of prognostic importance only in that younger patients tend to present more malignant grades of carcinoma and earlier metastasis to the axilla. Exploratory incisions, followed by immediate radical operation, do not seem to jeopardize the likelihood of cure. Recurrence in the operative field is rare if proper selection of cases and proper operation are carried out.

One Stage Thyroidectomy in Aged.—Richter and his colleagues state that 270 consecutive one stage thyroidectomies were performed on thyrotoxic patients from 50 to 77 years of age. Not one death occurred. During the period in which these patients were operated on, 900 thyroidectomies for thyro-

toxicosis in every age group were performed with three deaths. These data are presented as evidence in favor of the routine use of a radical one stage operation for thyrotoxicosis in the aged.

Diagnosis of Obscure Fever.—Keefer bases his remarks on a study of eighty cases of obscure fever. In any consideration of the diagnosis of an obscure fever, one must take into account geography, climate and the prevalence of certain diseases in a particular community. Also the history of previous infections, the possibility of contact with other known infections and the habits of the individual must be investigated. The methods employed in establishing a diagnosis varied with individual cases and included the isolation of a specific infectious agent, the demonstration of specific serologic reactions, the appearance of characteristic clinical signs of disease, the biopsy of tissue and the use of the x-rays. In a few, the diagnosis was established only by means of surgical exploration or by necropsy. In the group of cases in which fever was caused by infections, the commonest causes were tuberculosis, staphylococci, streptococci and undulant fever. While it is always important to approach the diagnostic problems of any disease from the point of view of etiology, it is always necessary to find the anatomic location of the disorder and then decide on its cause. Indeed, the anatomic location of a disorder often suggests the etiologic nature of the process. The second large group of cases in which fever was a prominent feature consisted of ten patients with tumors, the commonest sites being the gastrointestinal tract and the kidney. Diseases of the blood forming organs composed the next largest group and these included Hodgkin's disease, infectious mononucleosis and primary diseases of the bone marrow. The diagnosis in these cases depends on the careful examination of the blood, the clinical course and the use of bone marrow biopsy and sheep cell agglutination tests. As fever is usually the result of a temporary loss of the equilibrium between heat production and heat loss, it is not surprising to find that increased heat production without compensatory loss, normal heat production with an associated inability to lose heat in the normal fashion, or an actual central disturbance of the normal heat regulatory mechanism may cause an elevation of the body temperature above the normal level. One finds that fever may be a feature in hyperthyroidism or dinitrophenol poisoning in which there is a great elevation of the metabolic rate, or it may be a feature in diseases in which the patient has difficulty in losing heat through the skin. This may be true of patients with heart failure, in hypothyroidism, scleroderma, congenital or acquired absence of the sweat glands (congenital ectodermal dysplasia, congenital ichthyosis and acquired anhidrosis) or following drugs which suppress sweating as well as in the presence of anemia. All the foregoing features must be considered in the analysis of any case in which prolonged fever is a feature.

Juvenile Rheumatism in London. F. Bach, N. G. Hill, T. W. Preston and C. E. Thornton.—p. 210.

Formol-Gel Reaction and Sedimentation Rate in Rheumatism.—Green and his associates determined the average erythrocyte sedimentation rate of 102 male rheumatic convalescents from 16 to 19 years of age, the hematocrit volume and the formol-gel test. In 99.2 per cent of the patients, on discharge from hospital, the erythrocyte sedimentation rate was more than 80, and in 81.4 per cent the hematocrit volume was 45 or over. The formol-gel test was usually negative. The 464 results of erythrocyte sedimentation rates and formol-gel tests on blood specimens from the 102 cases are compared. Positive formol-gel reactions occurred in 97.1 per cent of specimens with an erythrocyte sedimentation rate below 60, as compared with 2.6 per cent in specimens with rates above 80. In 92.3 per cent of fifty-four specimens with hematocrit volumes less than 40 a positive formol-gel reaction was obtained. The formol-gel reaction was much less affected by delay than was the sedimentation test. In its quantitative form the formol-gel test furnished useful information regarding the progress of the individual case. Its utility becomes even greater if there is any possibility of delay in the examination of specimens. Delay, even up to thirty-six hours after the collection of blood, had little or no effect on the formol-gel test, whereas any delay beyond three hours or less may completely invalidate the results of the erythrocyte sedimentation rate.

*Toxic Erythema, T. A. B. (Intravenously), Coronary Thrombosis and Sudden Death. R. J. Lockhart.—p. 318.

Toxic Erythema.—Lockhart reports the death of a patient following the injection of triple typhoid vaccine (T. A. B.) intravenously for desensitizing purposes. The patient was admitted with a generalized toxic erythema. The palms were cracked and fissured, dry and scaly and showed marked keratosis. The dorsum of both hands was red, dry and peeling. This appearance extended up both arms, gradually fading toward the shoulders, ending there in a few scattered red papules. The appearance of the lower extremities was similar. A red papular eruption covered both scapulas and extended down the sides of the thorax. Some improvement occurred with the local application of soothing and healing liniments and ointments. Sixteen days after admission an intravenous injection of T. A. B. (0.12 cc. in 1 cc.) was given to desensitize the patient, at which time the patient's temperature, pulse and respiration were 97 F., 96 and 20, but three hours later the corresponding figures were 103.6, 142 and 40. The patient showed no deviation from the normal reaction to such an injection until shortly after this time, when he suddenly collapsed. He was ashen gray, cold, sweating and gasping for air. The temperature fell rapidly from 103.6 to 98.5 F., respirations rose to 54 and the pulse became imperceptible. The heart sounds were inaudible, and crepitations were heard all over the chest. Epinephrine was given intravenously. The patient rallied slightly, becoming warmer, and his color improved. It was decided to repeat the epinephrine in thirty minutes, but within twenty minutes his condition rapidly deteriorated. A 25 per cent solution of pyridine betacarboxylic acid diethylamine was injected, but without avail. At postmortem examination there

was found a complex heart disease. A three to four months old infarct was present in the lower two thirds of the anterior wall of the left ventricle, and the coronary artery of supply, the anterior descending branch of the left artery, showed an organizing and partly recanalized thrombus about 2 cm. from its stem. Immediately proximal to this there lay a second—a recurrent—thrombus, fresh and unassociated with any new infarct changes. This left coronary artery and to a lesser extent the other branches had for some time been seriously occluded by atheromatous disease. In view of the postmortem observations the author wonders whether the second thrombus was coincident with the injection or precipitated by it. He can find only four cases in the literature in which acute thrombosis has occurred following the use of T. A. B. injections. Petersen (1921) has classified the clinical results of the so-called local reactions produced by foreign protein under three heads: stimulation of inflammatory foci of infectious or noninfectious origin and stimulation of latent diathetic phenomena. It is believed that the present instance probably falls under the last heading. The author suggests that electrocardiograms as a routine would seem to be the best safeguard against similar misfortunes in subsequent cases in which this treatment is employed.

Dark Adaptation and Vitamin A Intake.—According to Thomson and his co-workers, a modification of Edmund and Clemmesen's method was used to assess degrees of dark adaptation in a scheme of an extensive clinical and dietary survey in order that its usefulness for diagnosing vitamin A deficiency might be determined. However, it soon became apparent that the results were difficult to interpret in many cases owing to the presence of two variables (i. e. the light control by means of Tscherning glasses and the range of test letters). The power of distinction might be excellent at the low illuminations and poor at high illuminations or vice versa. For this reason a new adaptometer was designed in which only a black test letter was used and with another type of light control which could measure finer gradations than the Tscherning glasses. The method described differs from most others in using white light for the test. Results will be reported of an investigation into rates of dark adaptation obtained in groups of subjects whose diets differed widely.

- *Fatal Poisoning by "Meta Fuel" Tablets. D. R. Lewis, G. A. Madel and Joan Drury.—p. 1283.

Dental Sepsis, Anemia, Dyspepsia and Rheumatism.—Vaizey and Clark-Kennedy studied the after-histories of 234 outpatients in whom all the teeth had been removed for various reasons. Seventy-six of these patients had previously suffered from dyspepsia, and the teeth had been removed on the theory that dental sepsis was responsible for their condition. Only six were benefited. Thirteen had previously suffered from rheumatic symptoms, and extraction of septic teeth appeared to have had a beneficial effect in five. In 126 the teeth had all been extracted for purely dental reasons. In thirty-nine of these patients symptoms of dyspepsia and in nineteen symptoms of rheumatism developed. The widely accepted relation between dental sepsis and dyspepsia and rheumatism is questioned. The mechanical factor resulting from inadequate teeth would appear to be more important than the septic factor in the pathogenesis of dyspepsia. A healthy mouth is valuable largely because it leads to conservation of the teeth. When extraction cannot be avoided, it seems that early, adequate and efficient prosthetic dentistry is essential in the prophylaxis of all types of dyspepsia.

Fatal Poisoning by "Meta" Tablets.—"Meta" is the trade name for tablets used as fuel at picnics. Lewis and his co-workers state that the tablets may be easily mistaken for the popular peppermint lozenge. It is produced by the polymerization of metacetaldehyde and its activity is far greater than that of its isomer paraldehyde. According to Gautier (1928), combustion of meta cannot produce poisoning. It is not scheduled as a poison and its sale is unrestricted. The gardener has taken advantage of its poisonous character to kill slugs and snails, and the method of mixing it with bran has been responsible for the innocent slaughter of many wild birds. It is slowly absorbed from the intestine, and by its poisonous action on the central nervous system it produces drowsiness and convulsions. The majority of the recorded cases of accidental poisoning by meta have been in young children, and most of the cases in adults have been attempts at suicide. The fatalities have all occurred in the young. The death of a boy of 2½ years due to "meta fuel" is reported. The authors conclude that to protect the child the public should be warned of meta's dangerous qualities and the state should introduce measures for a safer distribution.

- *Influence of Acid Feeding on Utilization of Mineral Elements. S. V. Telfer.—p. 257.
- Anesthesia and Analgesia in Obstetrics. E. B. Cowan.—p. 269.

Influence of Acid Feeding on Mineral Utilization.—A metabolic experiment has been carried out by Telfer on a young subject maintained exclusively on a milk diet affording a large mineral intake, to ascertain the effects of acid ingestion (hydrochloric acid) on the utilization of the mineral elements. It was shown by the increase in the renal output of lime, magnesium and phosphoric acid and in the ratio of urinary to

fecal phosphorus that a higher degree of absorption of all the components of the mineral intake is induced. The quantities retained are slightly diminished, which would appear to indicate that the process of calcification is adversely affected, presumably through the absorption of an excess of acid or of acid products. From the increase in absorption and the fall in retention it is inferred that the administration of hydrochloric acid must tend to increase the concentration of the mineral elements in the blood. Under the conditions of the experiment the excess of phosphorus eliminated by the kidney after acid ingestion is derived from the intake and is primarily dependent on an increase in absorption; but it includes a small proportion of phosphorus which in normal circumstances would be utilized in growth, probably with lime in the process of calcification. The changes produced by the administration of hydrochloric acid in the treatment of postoperative tetany are described.

Recurrent Toxemia of Pregnancy.—As the available material on recurrent toxemia of pregnancy is scanty, Kellar draws attention to this condition and suggests that those who have cared for such patients record their observations. The author states that, according to current beliefs, a woman who recovers from a toxemic pregnancy may be affected in one of the following ways: 1. She may recover completely and not show any signs of disease whether or not she has further pregnancies. 2. She may develop frank glomerulonephritis and her condition deteriorates progressively, death being accelerated by further pregnancies, which, however, are apt to terminate prematurely. 3. She may remain perfectly well between her pregnancies but with each successive pregnancy toxemia ensues. It is particularly this type of patient that the author's paper is considering. He discusses the pathologic records of three patients suffering from recurrent toxemia. Evidence of chronic glomerulonephritis was not found in any of these three cases. In one case there was generalized arterial thickening of the smaller renal vessels and the renal lesion was typical of essential hypertension. In summarizing the admittedly scanty postmortem material he finds that a woman dying months or years after a toxic pregnancy is far more likely to have generalized arteriosclerosis than glomerulonephritis. Clinically there is a great tendency for a woman who has had a toxic pregnancy to develop persistent hypertension in subsequent years. Pregnancies which occur after the initial toxic pregnancy are liable to be complicated by toxemia in a majority of cases. Death occurring in this group of cases takes place most commonly from the results of prolonged hypertension on the heart, brain and kidney. Hypertension will develop in from one third to one half of these women irrespective of the number of pregnancies. From the established clinical and pathologic facts it seems possible to the author to draw the following conclusions: 1. Toxemia of pregnancy and essential hypertension are in some way closely linked. 2. Toxemia of pregnancy does not appear to be a cause of essential hypertension. 3. It would seem that the woman in whom essential hypertension is destined to develop in later life is peculiarly liable to toxemia of pregnancy. 4. Toxemia will tend to recur in such women and eventually permanent hypertension will develop, but this would have been attained even if the patient had never borne a child. 5. Toxemia of pregnancy may hasten the onset and progress of essential hypertension.

Placenta Praevia.—With the object of ascertaining the local incidence and the factors that influence the mortality from placenta praevia in Colombo, Caldera analyzed the case records of 39,704 (26,116 deliveries) patients who were admitted to the

De Soysa Lying-in Home during the last five years. There were 251 cases of placenta praevia among the 26,116 labors. The term "central" is used when the placenta covers the os completely, "marginal" when it covers only a part and "lateral" when it does not cover the os at all. In the present series 29.5 per cent of the cases were central, 41 per cent marginal and 29.5 per cent lateral. The largest number of cases of placenta praevia occurred in women from 26 to 30 years of age and then in those from 31 to 35 years of age. Of the cases of placenta praevia 167 attained a maturity of thirty-seven weeks. There are fourteen cases of abnormal presentations: ten breech and four oblique. During the last four years there were 199 cases of placenta praevia with twenty-three deaths, giving a maternal mortality of 11.5 per cent. The figures for 1933 are not included, as some of the records were not available. Of the twenty-three deaths, eleven occurred before delivery; in six of these death could be attributed solely to hemorrhage and in five shock following podalic version was an important contributory factor. The remaining twelve patients died after delivery. The deaths in three were due to puerperal sepsis, in eight to shock following podalic version and in one to delivery by the forceps. Thus in no less than twenty cases the cause of death was hemorrhage complicated by shock. Both the variety of placenta praevia and the method of treatment have a marked bearing on the prognosis not only on the life of the mother but also on the life of the child. The maternal mortality of the central variety was four times that of the marginal and sixteen times that of the lateral variety. The percentage of stillbirths for the central, marginal and lateral varieties was 69.6, 49.4 and 45, respectively. Podalic version was the method of treatment adopted in eighty-seven cases. The maternal mortality was 17.2 per cent and the fetal mortality 74 per cent. In thirteen cases of breech presentation the maternal mortality was 7.7 per cent and the fetal mortality 69.2 per cent. Cesarean section is the safest method of delivery for both the mother and the child, and although only five were delivered by this method there were no maternal or fetal deaths. The membranes were ruptured artificially on thirty-eight occasions. There were no maternal deaths and the fetal mortality was 39.4 per cent. Expectant treatment was carried out in forty-three cases, with four maternal deaths and ten stillbirths. The maternal prognosis was most favorable during the earlier period, from twenty-eight to thirty-one weeks of gestation, but the survival rate of the infants at this period was necessarily low.

Virus of Lymphocytic Choriomeningitis.—In examining material from patients with acute symptoms suggesting involvement of the nervous system, MacCallum and Findlay isolated the virus of lymphocytic choriomeningitis from four patients. The case that they describe was originally diagnosed on clinical grounds as acute anterior poliomyelitis, but the virus of lymphocytic choriomeningitis was isolated from the cerebrospinal fluid once and from nasopharyngeal washings twice. The other three cases will be discussed in a later publication.

The isolation of the virus of lymphocytic choriomeningitis on three separate occasions from the same patient and the failure to incriminate the virus of poliomyelitis indicate to the authors that the virus of lymphocytic choriomeningitis was responsible for the clinical condition. The possibility of a double infection must be considered, but as the nasopharyngeal washings failed to yield evidence of poliomyelitis virus there is no experimental proof of its being present. The virus was still present in the nasopharynx eight and twelve weeks after the onset of the illness. Failure to demonstrate neutralizing antibodies in the serum eight weeks after the illness started could, the authors state, be taken as evidence against the specificity of the infection, but the slow development of antibodies in patients infected with this virus has been stressed by Scott and Rivers and by Howard. The data of the present case suggest that the virus of lymphocytic choriomeningitis is probably present at some period in the nasopharynx of individuals suffering from this infection. It may possibly be present in the same situation in healthy carriers, and in persons suffering from febrile symptoms without definite involvement of the nervous system. There is need for renewed study and interest in the cause of acute infections of the central nervous system of unexplained etiology. The virus of lymphocytic choriomeningitis should be searched for not only in cases clinically resembling acute aseptic lymphocytic meningitis but also in other acute nervous and febrile complaints of unknown origin.

Sternal Puncture.—The history and technic of sternal puncture are described by Hynes and an account is given of the changes in the marrow in 109 cases, including thirteen normal subjects, forty-four cases of leukemia, seven of untreated pernicious anemia, six of aplastic anemia, six of myelosclerosis and instances of other conditions. The marrow picture in the so-called aleukemic leukemias does not differ from that of the corresponding leukocythemic leukemias. Irradiation of the spleen in chronic myeloid leukemia improves the marrow picture together with the blood picture. There is a characteristic marrow picture in the various types of anemia, but neither aplastic anemia nor myelosclerosis can safely be diagnosed by sternal puncture. For these a trephine specimen is required. The greatest value of sternal puncture is in the diagnosis of leukemia with leukopenia. The marrow picture in leukemia, whatever the peripheral blood picture, is characteristic. It is extremely cellular, with the normal cell ratio greatly altered by an increase in primitive leukocytes. The proportion of primitive erythrocytes is depressed, but the percentage of erythroblasts is almost equal to that of normoblasts. This "maturation defect" is probably associated with the macrocytic anemia which is almost always seen in leukemia; it differs from the maturation defect of pernicious anemia in that there is no premature hemoglobinization of the erythroblasts. In leukopenic ("aleukemic") forms of leukemia the marrow does not differ from that of leukemia with leukocytosis.

Dermatomyositis and Progressive Scleroderma.—Dowling and Griffiths believe that dermatomyositis and progressive symmetrical scleroderma are one and the same disease, a process which involves chiefly the blood vessels, the skin and the skeletal muscles throughout the body. The muscles in the two conditions undergo the same microscopic alteration. The

muscular symptoms also are the same in the two diseases, ranging from mild to extremely severe myasthenia. The cutaneous and vascular changes are of the same order. Raynaud's symptoms arise in both, though more frequently in scleroderma with sclerodactylia than in the type of case that is usually termed dermatomyositis. The initial cutaneous symptom in both conditions is usually edema, and the same regions are affected with remarkable constancy; when the edematous phase settles down, the skin becomes densely or superficially sclerosed. In both muscle and skin the changes are degenerative, not inflammatory. Both progressive scleroderma and dermatomyositis have certain characteristics in common with thyroid disease and myasthenia gravis. The common factors are that: 1. The skeletal muscles show exactly similar pathologic changes in thyrotoxicosis, myasthenia gravis and dermatomyositis. 2. Clinically, the muscular symptoms in dermatomyositis and thyrotoxicosis are similar, though different in degree. 3. Creatinuria is common. 4. Certain disturbances in carbohydrate metabolism in thyroid disease have their counterpart in dermatomyositis, and calcium metabolism is affected in both. 5. Microscopically normal thyroids are not found in any case of progressive scleroderma. The authors state that these facts suggest that there is possibly a link between dermatomyositis or progressive scleroderma, thyrotoxicosis and myasthenia gravis. Dermatomyositis is an obscure condition, but they doubt whether it ought to be classed as rare.

Diagnosis of Hydatidiform Mole by Biologic Assay.—Boycott and Smiles report a case which illustrates some of the difficulties and dangers of a diagnosis of hydatidiform mole based on biologic assay. They endeavored to investigate the upper limit of normality for the excretion of gonadotropic hormone in pregnancy. Five women from ten to twelve weeks pregnant were subjected to assay. A positive test was obtained with quantities of urine varying from 0.13 to 1 cc. and negative results with smaller quantities in each case. Urine was also obtained from two cases of hydatidiform mole. Although in one case expulsion of the mole had begun, the Friedman test was positive with 0.033 cc. and negative with 0.028 cc. of urine. Assay in mice showed more than 200,000 mouse units per liter of gonadotropic hormone. In the other case, in which the mole was actively growing, the Friedman test was positive with 0.01 and negative with 0.005 cc. of urine. One case of hyperemesis gravidarum of moderate severity was investigated, the patient being eleven weeks pregnant. The Friedman test was positive with 0.04 cc. of urine. One week later it was positive with 0.06 cc. and negative with 0.05 cc. of urine. The quantitative test in mice was inconclusive. Such comparable evidence as there is goes to show that some women with hydatidiform mole excrete more gonadotropic hormone than is found in any other disorder of pregnancy. On the other hand, cases of hydatidiform mole have been reported which gave a negative test in a rabbit. As far as can be ascertained, the majority of cases of active hydatidiform mole give values not far outside this zone of overlap. A case that the authors describe in detail showed a maximal excretion one tenth of that found in the case of active hydatidiform mole and one third of that in the case in which the mole was in process of expulsion. The patient was not treated for hydatidiform mole as the characteristic "doughy" uterus was absent; there was general improvement in her condition and the hemorrhages ceased. X-ray evidence was of considerable value. Biologic testing is used extensively for the diagnosis of the recurrence of hydatidiform mole or of chorionepithelioma. The case reported by Kobak, in which a normal ten weeks pregnancy was mistaken for a recurrence on the evidence of a high level of gonadotropic hormone in the urine and hysterectomy was performed, shows that even in this connection biologic testing has its dangers. Although it is probable that in some cases of hydatidiform mole a larger excretion of gonadotropic hormone occurs than in any other condition (except chorionepithelioma), on the whole diagnosis of hydatidiform mole on the biologic assay of gonadotropic hormone alone is unreliable.

Bitot's Spots in Ceylon.—Nicholls and Nimalasuriya encountered several hundred cases of changes in the bulbar conjunctiva of the eyes of malnourished children and others

in Ceylon, which they refer to as Bitot's spots. The pathologic changes, as seen by them, are of a definite type but do not conform to some of the descriptions given by other observers. They have never seen Bitot's spots extending to the cornea, for they do not regard the changes in the cornea which occur in keratomalacia as extensions of Bitot's spots; and the spots in the great majority of their cases have in no way resembled foam. Bitot said that all his patients had night blindness, but this has not been present in most of the authors' patients. Bitot's spots tend to be chronic and it is necessary to give large doses of fish liver oils or concentrated preparations of vitamin A to clear them. The authors state that it may be that there are two forms of xerosis or keratinization of the bulbar conjunctiva: an acute form in which the changes take place rapidly, forming loose accumulations of degenerate epithelium which appear foamy, and a chronic form in which the accumulations of epithelium take place more slowly and are more compact. If this is so, possibly the first form is more likely to occur as a rare condition in countries in which diets deficient in vitamin A are not in common use, and the second form, as in their patients, will be seen among populations who have become more or less biologically adapted to diets deficient in this vitamin, and consequently their reactions to the deficiency are more chronic.

Chronic Infection and Atherosclerosis.—Jones and Rogers cite examples which show that in certain instances of atherosclerotic heart disease there exists a clinical relation to infection and that the removal of the latter beneficially affects the course of the former. They have demonstrated the presence of micro-organisms in the walls of all atherosclerotic vessels in which they searched for them. They stress the importance of the work of Larsell and Fenton, who demonstrated a direct pathway between the paranasal sinuses and the heart, along which streptococci have been shown to travel. And also Winternitz, Thomas and Le Compte have seemingly proved beyond question that the artery wall responds to injury in a true inflammatory manner with increased vascularity and that atherosclerosis is a common result of such reactions. All these investigations point to more than a possible relation of atherosclerosis to chronic infection.

Hematologic Studies in Nutrition.—On the basis of his experimental studies, Latsky asserts that copper possesses an adjuvant function necessary to iron for hemoglobin synthesis. Its property is probably of catalytic nature. It probably has no influence in the absorption of iron but plays no insignificant but a phenomenal part in the synthesis or conversion of this inorganic iron into hemoglobin. Iron plus copper administration results in a dramatic response of general blood regeneration as compared to the insignificant low and slight response of iron therapy alone. Iron plus copper administration also improved the growth, health and general well being of the animals to a more marked extent than did iron alone. Iron plus copper administered to anemic rats resulted in an immediate reticulocyte response, leading to quick maturation of the erythrocytes. The sizes of the matured erythrocytes compared most favorably with those of the most ideally normal animal. Iron alone could not produce this marked hemoglobinization of erythrocytes.

Pneumococcal Peritonitis: Clinical and Therapeutic Considerations (Eight Cases). R. Ducastaing.—p. 62.

Late Results of Ablation of Loose Articular Bodies.—According to Leriche and his associates, it is generally accepted as a demonstrated fact that the late results of the surgical ablation of loose articular bodies are good. However, since exact information about this problem is wanting, the authors decided to investigate the cases of loose articular bodies in which surgical treatment was given at their clinic in the years 1926-1938. Their material comprises thirty-one cases. According to the modes of origin, the authors differentiate different groups. First they discuss twelve cases in which osteochondritis dissecans existed. In three of these cases there were two or more loose bodies. The late results were excellent from the clinical point of view. Of twelve patients who had been operated on from six months to twelve years previously, ten declared that the functional results were perfect. In one case, in which arthrotomy of the knee had been done by means of a U-shaped incision, a slight limitation of movements was retained. In another, in which the joint still contains a small loose body, the movements are likewise slightly restricted. The late results are quite satisfactory also from the roentgenologic point of view. X-ray examination of ten patients after intervals of from six months to twelve years showed the old niche in six, whereas in the four others it was invisible. The structure of the epiphysis (outside the niche) and the delineation of the interline were normal. Only three patients presented discrete signs of chronic arthritis, some softness of the interline or mild structural modifications of the epiphysis. The cures seem to be final as a rule. Nevertheless, the possibility of a relapse plays a part in two cases; in one a new loose body is visible, in the other there is a new niche surrounding the first one. The second group of patients discussed were those with articular chondromatosis. The authors show that in these patients the loose articular bodies are often numerous; they cite cases in which from twenty to twenty-five were found. They also observed that synovectomy is useless for these patients. Of the eight patients of this group who underwent surgical treatment for loose articular bodies, only three could be reexamined. In two of these the late results were excellent, whereas in the other one they were unsatisfactory. In the patients of the third group, the loose articular bodies were of traumatic origin. Of nine patients of this group who had been operated on, five could be reexamined from three to ten years after the operation. The late results were good in all of them.

47: 1061-1076 (July 5) 1939

- *Lumbocrural Neuralgias of Colonic Origin. M. Brulé and H. Garban.—p. 1061.
Lactic Ferment Therapy of Vesical Infections. A. Fournier.—p. 1062.

Lumbocrural Neuralgias of Colonic Origin.—Brulé and Garban direct attention to the frequency with which patients who have disorders of the large intestine complain of pains in the kidneys. The pain is localized in the lumbar region, from the twelfth rib to the iliac crest; it is localized especially in the superior third of the buttock, a little outside the sacro-iliac symphysis and in the root of the thighs, from the antero-superior iliac spine to the pubic symphysis. At the fold of the groin it radiates inside toward the spermatic cord or the round ligament, to the scrotum or the labia majora and toward the internal surface of the thigh. From the anterior extremity of the iliac crest it crosses the antero-external surface of the thigh, encircles the knee and at times descends along the leg to the great toe. Walking is painful because of the lumbar rigidity and the heaviness in the lower limbs. The pains are intensified by brusque movements and lessened by rest and warmth. They are influenced directly by changes in the intestinal condition; they are aggravated by increased constipation

or a mistake in diet and subside only with the amelioration in the colonic disorder. The most constant of these painful points are the gluteal, femorocutaneous, crural and obturator. These neuralgic points correspond to the emergence of sensory branches of the lumbar nervous plexus. There is no neuralgia in the region of the sciatic nerve. Lasègue's sign is negative, whereas the inverse maneuver, that is, hyperextension of the thigh onto the pelvis, often provokes a severe pain at the femorocutaneous and the crural points. The lumbosacral neuralgias develop in organic disorders of the colon, which may be of the acute or of the chronic type. In case of acute disorders such as appendicitis and diverticulitis the pain spreads rapidly over the lumbar region, the buttocks and the inferior members and it regresses again with the same rapidity. In chronic lesions, such as cancer, only a single nervous branch, the femorocutaneous or the crural one, is usually involved. Slow progressive evolution provokes a veritable neuritis and terminates in paresthesia with partial atrophy of the muscles of the thigh and abolition of the patellar reflex. Like the colonic pain, the localization of the lumbocrural neuralgia varies; it may be unilateral or bilateral or oscillate from one side to the other. One day it may be localized in the lumbar region and the following day in the buttocks or the thigh. Often it appears in an atypical form; there are vague pains which the patients designate as rheumatic. The author says that treatment of the cause, that is of the intestinal disorder, is more effective than is local therapy.

Iron Metabolism of Premature Infants.—Wallgren's investigations were made on eight prematurely born infants whose ages varied between 2 weeks and 8½ months. Their weights at birth were between 1,040 and 2,100 Gm. All the infants were nursed at the breast. During the two or three months in which there usually takes place a physiologic post-fetal destruction of the blood, eleven of thirty-one tests revealed a negative balance for iron. The low hemoglobin values of prematurely born infants in comparison with those of the infants born at term, toward the end of the aforementioned period, is not attributable to a lack of iron provoked by an abundant elimination of iron, because during this period, when the hemoglobin value cannot be raised by the external introduction of iron, the quantity of iron liberated by hemolysis and thus available is abundant. During this same period no relation whatever can be demonstrated between the iron balance and the hematologic picture. During the first four months of existence the iron balance is principally in relation with the degree of storage of the iron liberated by hemolysis, but this storage varies in quantity in different subjects. If the hematologic values of the prematurely born infants are inferior to those of infants born at term, so is this attributable to the fact that the hemolysis is more intense in the premature, probably by reason of the more embryonal nature of their blood at the time of birth. The inferiority of the hematologic values in the prematurely born can hardly be explained by the hypothesis that the bone marrow functions less satisfactorily. The tests made on prematurely born infants after the period of postfetal hemolysis generally revealed a positive balance; among eleven tests there were only three that were negative. This result signifies that at this period the organism uses sparingly the iron stored in the organism or furnished by the food. A comparison with what takes place in the infants born at term reveals no essential differences that would explain why the hematologic values of prematurely born infants are at this time inferior to those of infants born at term. The abundance of reticulocytes in the blood of prematurely born infants does not indicate that their hematopoietic organs are in a state of functional immaturity which renders them incapable of produc-

ing erythrocytes as rapidly as infants born at term. The volume of the blood must increase more rapidly in the prematurely born infant than in the infant born at term, and thus they first require more hematogenic material, especially iron, than do the latter. The function of the hematopoietic organs is likewise taxed more in prematurely born infants. It is probable that their greater needs cannot always be satisfactorily met and this discrepancy between need and supply, on the part of the bone marrow and the iron, is the reason that the prematurely born infants are not always able to maintain their hematologic values at the same level as the infants born at term. The fact that some prematurely born infants develop an anemia whereas others do not can be explained either by a different degree of prematurity or by different functional capacities of the bone marrow and by the different iron supplies in the depots. Nevertheless it is absolutely certain that factors of an exogenous nature, such as errors in feeding and care or infections, are of extreme importance in the anemias of prematurely born infants. These infants are exposed to such exogenous factors to a greater extent than are the infants born at term; moreover, they are more susceptible than the latter.

**Clinical Value of Determination of Coagulability of Blood by Coaguloretractovisometry During Pregnancy and in Course of Gynecologic Disorders.* L. Blacher.—p. 624.

Coagulability of Blood During Pregnancy.—Blacher made his studies on the coagulability of the blood of pregnant women and of patients with gynecologic disorders with his own method of coaguloretractovisometry (abstracted in *THE JOURNAL* April 22, 1939, p. 1640). He found that during the final weeks of normal pregnancy the coagulability of the blood is normal, with the exception of an augmented retraction of the clot. On the other hand, during early pregnancy, complicated by gravidic vomiting, the coagulability of the blood exhibits greater or lesser deviations from the normal. In extra-uterine pregnancy all the reactions of the coagulability of the blood are altered: most disturbed is the force of retraction of the coagulum. The type of metrorrhagia and the quality of the blood in extra-uterine pregnancy can depend on the extent of the disturbances of the coagulability. The ovarian dysfunction during the menopausal period is the direct cause of variations of the coagulability of the blood and especially of the delay of the reaction of the retractility of the clotted blood and of the degree of the force of its retractility. The curettage, as far as the surgical procedure permits checking for a time the hemorrhage due to ovarian dysfunction, especially during the climacteric period, effects attenuation and even the disappearance of the fluctuations of the reactions of the coagulability of the blood. In inflammatory lesions of the genital organs, the coagulability of the blood indicates a retardation of the reaction of coagulability and of coagulation, a notable retardation of the reaction of retractility of the coagulated blood and a normal or slightly diminished force of retraction of the clot. In the acute and grave cases as well as in the morbid states complicated by profuse metrorrhagia, the alterations of the coagulability are severe. The coagulability is irregular in adenomyomas of the uterus. In uterine myomas with signs of hyperactivity of the thyroid, the deviations are more pronounced than in the benign myomas of this organ. In ovarian cysts the coagulability of the blood is normal. In cancers of the uterus the coagulability of the blood shows a discord between the reaction of the coagulation and that of retractility of the clotted blood as well as between the reaction of retractility and the force of retraction of the clot; the latter is augmented. A characteristic aspect of these morbid states is the normal degree of coagulation beside the much changed value of the reaction of the retractility of the clotted blood and of the force of retraction of the coagulum and vice versa. The peculiar types of coagulability of the blood observed in various morbid states of the genital organs and of pregnancy undergo changes when, apart from the gynecologic disease or the pregnancy, the patient shows still another disorder, and especially a disease of the liver.

**Pathogenesis of Intralaryngotracheal Goiter.* C. Wegelin.—p. 593.

Rare Complications of Tonsillectomy. L. Rüedi.—p. 595.

Progress in Treatment of Patients With Diabetes Mellitus. V. Jonäs.—p. 598.

Rare Case of Erythromelalgia. K. S. Saracoglu.—p. 607.

Pathogenesis of Intralaryngotracheal Goiter.—Wegelin was able to connect the theories of von Bruns and Paltau, for he observed that intralaryngotracheal goiter occurs in fetuses and newborn infants and that even at this stage there exists a connection between the external and internal portion of the thyroid. He found that the bridge of tissue is between the cricoid cartilage and the first tracheal cartilage and that it infiltrates the cricotracheal membrane. Moreover, he was able to observe a preliminary stage of the intralaryngotracheal goiter; in a newborn child and in a child aged 5 years he detected thyroid tissue in the submucosa of the trachea and in the cricotracheal membrane, although these sites showed no macroscopic swelling. In these cases the external thyroid was greatly enlarged. On the basis of these observations the author assumes that in case of goitrous hyperplasia the thyroid may grow into the larynx and trachea during the fetal period but that a later invasion is likewise possible. In studies on goiter in white rats the author was able to make observations which corroborate Paltau's opinion. The animals received only cooked foods (oats and maize gruel) and some bread. They developed either diffuse or nodular goiters and the author observed that an intralaryngotracheal goiter develops when the enlarged thyroid penetrates between the cricoid and tracheal cartilages and spreads under the mucosa. All stages of invasion could be demonstrated. Since such changes are absent in normal thyroids, their presence seems to indicate that in human subjects also intralaryngotracheal goiter is caused chiefly by the goitrous proliferation of the thyroid, during either fetal or extra-uterine life.

Studies on Enzymatic Cleavability of O-Acetylneurin and Influence of Aneurin on Choline Esterase. H. Süllmann and H. Birkhäuser.—p. 648.

Percutaneous Osteodesis.—Creysse and Roulet define as percutaneous osteodesis a method for the immobilization of non-surgically reduced fractures in which two parallel wires (Kirschner) are introduced through the skin and passed through the bony parts vertically to the fracture surface. Evaluating the advantages of this method, the authors stress that the material used to effect the synthesis is easily applied and easily removed. Moreover, the method is comparatively harmless; the simple perforation of the skin and bone reduces the danger of infection. If the technic is faultless, there is almost no danger of an injury to vessels and nerves. The value of the method is proved also by the results; it effects an excellent immobilization, the prosthesis material is well tolerated, there is no retardation of consolidation and the functional results are good. In view of the results which have been obtained with this method in the past, the authors think that it is indicated among others in spiral fractures. All fractures of this type, even those with no immediate dislocation, should be treated with this method, except when there are contraindications of a general or local nature. In obliquely bent fractures the described procedure should be used if a good reposition can be obtained; however, in this case the wires must be left in place for a comparatively long time. In other types of fractures (double fractures, splintered fractures), this procedure is more difficult and indications for it cannot be systematized. In old fractures which had been inadequately reduced and in which a surgical intervention is necessary, osteodesis can be done in the presence of the opened fracture and with removal of the interposed fibrous tissue. In these cases it can be chosen among other methods of osteosynthesis, over which it has the advantage that it is simple and that the prosthesis material is easily removed.

Pathogenesis of Stenosis of Conus Arteriosus of Heart. G. Mottura.—p. 493.
*Hepatorenal Syndrome. E. Zilocchi and A. Marini.—p. 607.

Hepatorenal Syndrome.—Zilocchi and Marini point out the importance and clinical significance of the renal lesions which may complicate operations on the biliary tract (the so-called hepatorenal syndrome). They describe the clinical picture and pathologic anatomy of the syndrome and report results of experiments which were carried on in normal dogs and which aimed to produce the syndrome. The animals spontaneously died within one and four months from the beginning of the experiment. The authors found that the syndrome can be experimentally induced from cholemia (ligation of the common bile duct) as well as from complete external derivation of bile (for a long time). Both procedures have a harmful effect primarily on the liver and secondarily on the kidney. The lesions of the liver are the first to develop. They consist of parenchymal degeneration which evolves to necrosis. Early during the development of degeneration the detoxicating functions of the liver are arrested and toxins are produced in the general and local circulation. A compensatory detoxicating hyperfunction of the kidney takes place, which is followed by development and evolution of renal functional and parenchymal changes of the same type as those which previously developed in the liver and also by development of the syndrome. According to the author the syndrome is caused by various toxins of synergetic action. The similarity of the hepatorenal symptoms to those which are observed in certain toxic conditions (such as burns and eclampsia in pregnancy) and the frequency of the syndrome in various experimental toxic conditions (autolysis of the liver, ligation of the common bile duct, intravenous, intramuscular or intraperitoneal injections of bile and total derivation of the bile) point to the toxic origin of the syndrome, which evolves with acute toxic clinical symptoms and ends with a terminal stage similar to that of uremic coma. The author calls attention to the fact that the results of his experiments do not conflict with proper indications of external derivation of bile in jaundice from obstruction of the bile ducts. Functional disturbances of the liver and kidney developed late in the course of the experiments, namely after more than a month of external derivation of bile, a duration which is never reached in the clinical application of external derivation of bile.

Intrahepatic Diffuse Calculosis: Pathogenesis. G. Dagnini.—p. 166.
*Ischemic Contracture of Volkmann's Type in Hemophilia. M. Paltrinieri.—p. 203.
Diffuse Neurofibromatosis (Recklinghausen's Disease). F. Cavazza.—p. 214.

Ischemic Contracture in Hemophilia.—Paltrinieri observed two cases of typical ischemic contracture of the hand in hemophilic patients. A mild trauma caused the formation of a large subfascial hematoma at the flexor region of the elbow and caused establishment of the contracture. Neither fracture nor external pressure existed in any of the cases. According to the author, his cases are rare but not unique. He believes that hematoma of the flexor region of the elbow or of the forearm is the main cause of ischemic contracture of the hand, either as a complication of fractures or when it follows a simple trauma. In either case the hematoma infiltrates the interstitial spaces around the local muscles, compresses the local nerves and blood vessels and causes ischemia and neuritis with consequent myopathy and the establishment of the contracture. The evolution of the condition depends on the acuteness of the nervous compression. The role of hematoma in the development of ischemic contracture of the hand is proved by (1) the possible identification of hematoma on microscopic preparations of tissues taken during operations in cases of ischemic contracture, (2) the presence of hematoma in all cases of supracondylar fractures (which may be complicated by ischemic contracture) and its absence in open fractures (which are never complicated by ischemic contracture) and (3) the cessation of the development of ischemic contracture when a large hematoma of the elbow region or of the forearm is drained early in the development of the contracture. The author therefore concludes that: 1. For the prevention of ischemic contrac-

ture (as a complication of fractures) it is advisable to reduce the fracture by transolecranic traction with wire. The arm is left in an upward position in order to favor defluxion of hematoma. 2. Early in the development of ischemic contracture without fracture or external compression it is advisable to ascertain the possible presence of ecchymosis and of hematoma of hemophilic origin.

*Indications of Surgical Intervention in Abscess of Lung. R. Paolucci.—p. 819.
Reduced Glutathione in Blood in Hyperthermia from Short Waves. G. Zuddas.—p. 825.
Erythema Nodosum of Tuberculous Origin: Case. T. Moruzzi.—p. 864.

Indications of Surgery in Pulmonary Abscess.—Paolucci observed 200 cases of pulmonary abscess, located in the right lung in 140 cases and in the left one in sixty. The diagnosis of abscess of the lung is made by x-ray examination of the lung immediately after appearance of the first typical sputum. Treatment, whether surgical or symptomatic, is determined by the evolution of the disease as shown by a second roentgenogram taken two weeks after the first one. Increase in the size and darkness of the image of the abscess in the second roentgenogram points to evolution of the disease and the advisability of an operation. Treatment of simple cortical abscess with pleural adhesions consists in paraffin plugging, which is followed ten days later by pneumonotomy and introduction, in the incision, of sterile gauze soaked in a barium sulfate solution. Ample pneumonotomy and ample drainage are indicated in putrid abscess. Massive gangrene of the lung as a rule is bilateral and refractory to treatment. In rare cases an ample pneumonotomy may be followed by elimination of large amounts of necrotic tissues and eventual recovery of the patient. The treatment of chronic supuration consists in progressive resection of the involved pulmonary tissues and in favorable cases by resection with the electrical bistoury. Bronchiectasis, alone or in association with pulmonary tuberculosis, calls for a lobectomy. Abscesses of the lung are multiple in a large number of cases. When they are remotely located in different lobes of the lung they are separately opened and drained. If they are close to each other they are opened through a thoracic wound, which may be large or small according to the resistance of the patient. If the wound is large the abscesses are depleted directly through the wound; otherwise one abscess is opened directly through the wound and the others are evacuated through the one which was previously depleted. A drain is left in either case. Artificial pneumothorax is never resorted to as a means for inducing collapse in the presence of abscess of the lung. Paraffin treatment can be resorted to in certain forms of pulmonary suppuration, either early as a preliminary procedure to pneumonotomy or as a complementary operation with the aim of filling large cavities, which are left in certain cases from destruction of large areas of the lung.

Influence of Nicotinic Acid on Coproporphyrinuria from Neorosephenamine. E. Scolari.—p. 545.
*Effects of Vitamin C on So-Called Postgonorrheal Urethritis. G. B. Cottini and M. Muscolino.—p. 563.

Ascorbic Acid in Postgonorrheal Urethritis.—According to Cottini and Muscolino the so-called postgonorrheal urethritis is primarily a local C hypovitaminosis and secondarily a local reaction of the urethra from postgonorrheal pathologic alterations of the epithelium and mucosa of the urethra. The diagnosis of urethritis with epithelial and mucosal changes is made from the appearance of the urethral secretion during microscopic examination, as it is rich in epithelial cells and does not contain pus cells and bacteria (or else it contains but few). In some cases postgonorrheal urethritis is due to extra-urethral infection or else to prostatitis or seminal vesiculitis. The authors report satisfactory results from the administration of intravenous injections of ascorbic acid in thirteen patients who were suffering from the condition. In all cases the urethral secretion was free from gonococci and the local and general treatments (which are generally resorted to in the condition) had failed. The injections were given to the patients every other day, in doses of 5 cc. of a solution containing 0.5 Gm. of ascorbic acid (equal to 1,000 international

units) for each injection, in a series of ten injections for each treatment. The treatment was repeated after twenty or twenty-five days of rest during which time the patients had no other treatment. The general condition of all patients improved. In the majority of cases the secretion rapidly diminished up to complete disappearance with recovery and persisted after reestablishment of sexual functions and up to the present time (more than a year after discontinuation of the treatment). In three cases of postgonorrheal urethritis in the presence of intestinal infection, prostatitis or seminal vesiculitis (one case of each) the treatment failed. The authors conclude that the treatment is of value in controlling postgonorrheal urethritis from epithelial and mucosal alterations and also in differentiating the forms of postgonorrheal urethritis which originate in extra-urethral infection or extra-urethral inflammation and which require proper treatment. The ascorbic acid treatment is simple, harmless and well tolerated. The authors' article is a preliminary report.

*Treatment of Postdiphtheric Paralysis with Vitamin B₁. P. Feige.—p. 333.

Use of Homogenous Serum in Treatment of Chronic Diseases. H. Boehnhardt.—p. 340.

Vitamin B₁ in Postdiphtheric Paralysis.—Reviewing 1,590 cases of diphtheria which were observed during the years 1936 and 1937, Feige found 100 cases in which postdiphtheric paralysis developed. Paresis of the soft palate was observed in ninety cases, paresis of the ocular muscles in twenty cases, paralytic symptoms of the legs in twenty-three cases, paralysis of the pharyngeal muscles in eighteen cases, paralysis of the respiratory musculature in four cases, paralysis of the musculature of the neck and back in three cases and paralysis of the diaphragm only once. Some of the children had more than one form of paralytic symptoms and in eighteen of the children the paralysis threatened life. Of the sixty cases in which the entire course of the postdiphtheric paralysis could be observed, thirty were treated with a preparation of vitamin B₁ and thirty either received no treatment for the paralytic symptoms or were treated with other medicaments. A comparison of these two groups of cases revealed that in those patients who were treated with vitamin B₁ the paralytic symptoms persisted on the average for 29.6 days, whereas in the other group they persisted on the average for forty-nine days. The author administered the vitamin B₁ by mouth and by intramuscular injection on alternate days. One day the children were given three times one tablet containing 1 mg. of the vitamin, that is, three times 400 pigeon units; on the following day they were given an intramuscular injection of 1 cc. of a vitamin B₁ preparation which contained 4,000 pigeon units. In remarks on the problem of the pathogenesis of postdiphtheric paralysis, the author cites observations of several investigators and suggests that these postdiphtheric paralytic symptoms are the result of the concurrence of a toxic impairment of the tissues with a lack of the B₁ substance, which has a ferment-like action. He thinks that this explains at the same time the success of the treatment with vitamin B₁.

Bone Marrow in Acidotic Osteopathy.—Markoff fed adult male rabbits for twenty-five days with cane sugar and water and during a second period of experimentation he fed the animals with cane sugar and turnips. Periodically the animals were subjected to blood tests, puncture of the tibia

and x-ray examination of the bones; later, microscopic studies were made on the bone marrow and the bones. He found that a diet which induces acidosis produces a hypertrophy of the bone marrow followed by a porotic process in the bones. Katase asserted that this osteoporotic process is of acidotic origin, but the author thinks that the coupling of medullary and osseous changes is so apparent that it indicates another pathogenesis of the osseous disorder. He observed similar conditions as those which Naegeli assumed for osteomalacia. The secondarily appearing bone changes represent, so to speak, a symptom of the primary process of medullary hyperplasia; that is, the osteoporosis is of myelogenic origin and the author designates it as myelogenic osteopathy. To the hyperplastic bone marrow there corresponds an increase in osteoclasts and, as the author had pointed out earlier, the fibrous condition of the marrow is usually accompanied by an increase in osteoblasts and osteosclerosis. Thus there exist typical relations between the condition of the marrow and the bone. This relationship can be expressed as follows: In the presence of cellular marrow there exists increased activity of the osteoclasts and osteoporosis; in the presence of fibrous marrow, increased activity of the osteoblasts and osteosclerosis. These two reactions are frequently only two phases of a marrow-bone reaction in which the development of fibrous marrow is preceded by a medullary hyperplasia. This can be estimated only by intravital studies on the bone marrow. An especially striking example is polycythemia vera, in which at the beginning a hyperplastic marrow corresponds to an osteoporosis, whereas in the later stages fibrous marrow with osteosclerosis is observable.

Larval Myxedema. O. Merkelbach.—p. 872.

*Nonsuppurative Thyroiditis. K.-H. Riwooldt.—p. 875.

Nonsuppurative Thyroiditis.—Riwooldt reports two cases of pure thyroiditis with no pyogenic evolution. Of neither patient (a man aged 40 and a woman aged 62) did personal and familial anamnesis indicate endocrine disorders; however, the inflammation of the thyroid was preceded by an infection (tonsillitis and an ulcerated tooth in the former, influenza in the latter patient). Therapy consisted in physical and lingual rest, ice compresses, liquid diet and proprietary medicaments for the former patient, with rest and iodide inunctions for the latter. Both patients recovered completely after a short period of convalescence without sequelae six months after or indications of exophthalmic goiter and myxedema. In the course of his epicritical remarks, based largely on the literature of the subject, the author ascribes the infrequency of pure thyroiditis in part to the omission of requisite diagnosis. He advises against cuneiform excision and favors a conservative symptomatic therapy. Etiologically it is impossible at present to determine whether bacteria or their toxins are at fault. He thinks, however, that temporary disturbances of the endocrine functions of the thyroid may be the causative factor, but without sufficient intensity to induce myxedema.

Pleurisy and Genital Tuberculosis.—Winkler and Wegemer say that studies on exudates by means of the culture method and the inoculation of animals have demonstrated that a large number of cases of pleurisy, particularly those of the wet type, are of a tuberculous nature. Then they review statistics on the comparatively high incidence of pulmonary tuberculosis after pleurisy, but they also show that the literature contains few reports about connections between pleurisy and extrapulmonary tuberculosis. Their own investigations on a possible relationship between pleurisy and genital tuberculosis in women were brought about by the observation that a large percentage of

women with genital tuberculosis previously had had pleurisy. Of sixty women with genital tuberculosis who were observed in a sanatorium for tuberculous patients, twenty-five (41 per cent) stated that they had had pleurisy and the authors show that the tuberculous etiology of these pleuritic processes cannot be doubted. Reviewing the material of a woman's clinic, the authors detected thirty-five cases in which the diagnosis of genital tuberculosis had been verified by surgery and in twelve (34.2 per cent) of these women the previous history disclosed a pleuritic or pneumonic process. Only three of the ninety-five women with genital tuberculosis had active tuberculous processes in the lungs. The majority of the patients developed tuberculous adnexitis within five years after the pleurisy. In view of the obscure genesis of many disorders of the genital adnexa, the authors suggest that a previous pleurisy be searched for. If the anamnesis of patients with lesion of the genital adnexa reveals a pleurisy, particularly the wet form, a tuberculous etiology should be taken into consideration.

Angina Pectoris, Adrenals and Iodine Content of Blood.—Raab and Schönbrunner cite observations which indicate that increases in the iodine content of the blood, with certain restrictions, can serve as a criterion of acute secretions of epinephrine. It was their object to investigate whether in patients with simple angina pectoris the secretion of epinephrine is absolutely increased or whether, as seemed more probable, there exists only an increased reactivity of the heart muscle (impaired by coronary sclerosis) to physiologic quantities of epinephrine. They observed augmentations in the total iodine content of the blood of healthy persons following the intravenous injection of epinephrine, after the patients had been exposed to low temperatures and after muscular exertion. These reactions of the iodine content of the blood to epinephrine and exertion could be weakened or completely abolished by ergotamine tartrate. The behavior of the iodine content of the blood of patients with simple angina pectoris did not deviate from that of healthy subjects during rest or after muscular exertion. Following the irradiation of the adrenals of patients with angina pectoris, the reaction of the iodine content of the blood to the exertion of work was either weakened or reversed. The authors regard these observations and reports in the literature as further arguments in favor of the assumption that elimination of epinephrine, which as such is physiologic, plays an essential part in the development of stenocardiac symptoms of patients with coronary sclerosis during work, excitement and exposure to cold.

Operation in Pelvic Kidney.—Chwalla shows that as yet there is no agreement about the best surgical method in case of pelvic kidney (pelvic renal dystopy). He thinks that the selection of the method of approach is dependent chiefly on the position of the pelvic kidney. In view of the importance of the exact localization of the organ, the author thinks that the term pelvic kidney should be replaced by designations which indicate the exact position, such as dystopia sacralis, dystopia lumbosacralis, dystopia sacroiliaca and dystopia iliaca. Another factor, which is decisive in the selection of the operative method, is whether the pelvic kidney is infected or not. In this connection

he points out that in case of infection the surgeon will hesitate to employ the transperitoneal approach. Depending on the position of the pelvic kidney, the method of approach is more median or lateral, higher or lower. Other factors that must be taken into account are adiposity of the patient, size of the pelvic kidney, infection, adhesions and so on; that is, individualization is essential. The author describes a case in which the usual lumbo-abdominal transverse incision was made. From this incision the abdominal cavity was opened in order to obtain a survey over the renal recess and to ascertain the possible existence of a supernumerary kidney. On the other hand, extra-peritonization of the pelvic kidney with reduction of the peritoneal sac was done in spite of aseptic conditions in the kidney, so as to insure a normal postoperative course and discharge of the wound secretion through the incision in the soft parts. In the discussion of the case, the author points out that inspection of the renal region seemed advisable because supernumerary organs have been known to occur in unilateral pelvic kidney. On the other hand, many pelvic kidneys cause no clinical manifestations and the menstrual disturbances found a gynecologic explanation. However, these menstrual disturbances as well as the pains were completely counteracted only following the removal of the pelvic kidney, which at first had been regarded as a tumor. A survey of the literature revealed to the author that pelvic kidney is frequently mistaken for a tumor of the adnexa or of the uterus. He thinks that, aside from the menstrual disturbances, this is probably the reason why operations for pelvic kidney are more frequent in women than in men.

Postoperative Gastric Retention.—According to van Gelderen, postoperative retention of the gastric contents is a frequent complication of gastric surgery. Irrespective of the type of operation it develops chiefly in male patients who have undergone surgical treatment for peptic ulcer. The author cites statistical reports which indicate that, whereas in women the incidence of postoperative gastric retention varies between 4.6 and 6.4 per cent, in men the incidence is around 20 per cent. The author also observed a greater incidence during the spring months. He shows that this dyskinetic, chiefly spastic, disturbance of the gastric passage may be classed with visceral spasmophilia in patients with sympathetic disharmony who develop gastric ulcer. It is hardly ever possible to establish a definite anatomic cause of the postoperative retention of the gastric contents, and the author shows that this postoperative retention is a typical example of a disturbance of function without anatomic cause. He emphasizes that this disorder does not provide an indication for a new operation but that he, in collaboration with Borst, developed a chemical treatment for the patients with this functional neuromuscular disturbance. (Borst, in his paper in *Acta medica Scandinavica* 97:68 [Oct. 29] 1938, abstracted in *THE JOURNAL*, Jan. 7, 1939, page 94, recommends a solution of dextrose subcutaneously or cane sugar with a few drops of orange juice by mouth.)

Radical Resection in Gastric and Duodenal Ulcer.—Landelius reports studies on the early results of operations for gastric ulcer which were performed at his hospital during the decade from 1928 to 1937. Of 638 operations for gastric

and duodenal ulcers, 110 were made on perforated ulcers and 528 were performed during the free intervals. In thirty cases in which Billroth's first method was employed the mortality was 6.6 per cent; in sixteen cases of Billroth II retrocolica oralis inferior it was 6.2 per cent; in 415 cases of Billroth II retrocolica oralis in the manner of Polya-Reichel it was 3.8 per cent; in twenty-five cases of palliative resection according to Finsterer it was 24 per cent; in twenty-four cases of gastro-enterostomy it was 16.6 per cent; in eighteen cases of resection of peptic ulcer after gastro-enterostomy it was 11 per cent, and in the 110 cases in which the intervention was for perforating ulcer the mortality was 14.5 per cent. Among the patients in whom palliative resection was done, complications developed for which the surgical method could be blamed, such as perforation of the ulcer, leakage of the duodenal stump and acute hemorrhagic impairment of the pancreas. In none of the cases of Billroth II oralis was there leakage of the duodenal stump. All suturing of the intestine was carried out with two continuous tiers of catgut and infolding according to Lambert and without suturing of the mucous membrane. Resection of the stomach was done fairly extensively in order to obtain achlorhydria or considerable hypochlorhydria. Care was taken that the patients had a plentiful supply of fluid before and after operation. After recovery no dietetic therapy was employed. Persistent and severe changes in the wall as evidenced by x-ray examination (niche or deformity of the bulbus) in conjunction with anamnestic data were regarded as indications for an operation during the interval. The author cites figures which indicate that the mortality increases greatly with the age of the patients; moreover, the incidence of perforation is high among the patients of advanced age. On these grounds he deems it justifiable to advise operation in younger years and at an earlier stage of the disease.

Heparin in Arterial Embolism.—Olovson stresses the importance of early heparinization in cases of arterial embolism. He shows that treatment with heparin is most important before the operation or before the onset of the conservative treatment, the main object being to prevent thrombosis in the portion of the artery which is peripheral to the embolus, and in the collateral tracts. To be sure, heparin should be given also after the operation and during the conservative treatment, until the danger of secondary thrombosis has passed. Regarding the dosage of heparin, the author says that 1 mg. per kilogram of body weight prolongs the coagulation time to forty-five minutes. In his own arteriotomies on dogs he administered a single large dose; that is, 5 mg. per kilogram of body weight. He began the operation about ten minutes after the intravenous injection of this dose of heparin. As suture material he employed silk which had been saturated with heparin. Observations on bleeding in dogs and rabbits in the case of wounds and of arteriotomy under the influence of heparin revealed to the author that the administration of heparin caused the bleeding to last longer and to be more intense; however, no after-bleeding occurred and no hematoma was formed; a local hemostyptic proved to have a good effect; in no case of arteriotomy did secondary thrombosis occur.

Allergic Reactions by Urographic Contrast Medium.—Hultborn gives an account of seven cases in which complications developed following the injection of urographic contrast medium. The symptoms were interpreted as allergic reactions elicited by the contrast medium. Three of the patients had only urticaria and temporary edema but the other four, shortly after the injection, had severe symptoms of shock, which in one were combined with urticarial erythema. Anamnestic inquiries revealed that four of the patients had a previous history of allergic symp-

toms in the form of asthma or urticaria. One of the patients with the shock reaction, a woman aged 56 who had a normal nitrogen, did not eliminate the contrast medium but showed bilateral "filling" which was interpreted as secondary to the shock. About thirty-six hours later the woman presented symptoms of uremia, which disappeared after one week. It is assumed that the uremia was likewise caused by the shock. On reviewing the literature the author found reports of eight similar cases, one of which had a fatal outcome. He says that these complications have developed after different urographic contrast mediums. He advises that, before a contrast medium is injected for urographic purposes, inquiries should be made regarding the existence of earlier allergic symptoms. In cases in which there is a positive history in this respect, caution is necessary with intravenous urography. If complications arise, it is advisable to administer calcium preparations intravenously and epinephrine subcutaneously. In case of shock, analeptics should be given and, if the shock is severe, a permanent intravenous drip should be resorted to.

*Pathogenesis of Bundle-Branch Block Illuminated by Electrocardiographic Changes in Precordial Leads: Remarks on Relation Between Bundle-Branch Block and Other Preponderance Curves in Precordial Leads and Their Relation to Infarction Curves. V. Mortensen.—p. 1971.
*Two Cases of Inhibition of Bone Marrow Due to Splenomegaly. J. Schousboe.—p. 1980.

Pathogenesis of Bundle-Branch Block.—Mortensen describes the electrocardiographic changes in sixteen cases of bundle-branch block. He finds much conformity between the changes in lead 4F in left bundle-branch block and in Lead CF₂ in bundle-branch block of different Bayley types, indicating that Bayley's types represent complete right bundle-branch block. The R wave is reduced or absent in CF₂ in left bundle-branch block. A similar change is found in marked left preponderance. The hypothesis is presented that the normal size of the R wave in CF₂ and 4F depends on a certain normal relation between the conduction through the two ventricles and that the diminished R wave which may appear in marked left preponderance and in more pronounced degree in left bundle-branch block depends on a relative delay in the conduction through the left ventricle, either because of changes in the conduction system or because of hypertrophy of the left ventricle. From the even transition between left bundle-branch block, new terminology, and marked left preponderance it seems likely that marked left preponderance is due to a lesser degree of delay in the conduction through the left ventricle, and such delay is in most cases explainable by hypertrophy of the left ventricle. The author says that the new terminology for bundle-branch block brings the various theories of the cause of left preponderance into a more probable connection with one another. The view that delay in conduction is the direct cause of left preponderance also explains the cases of marked left preponderance without hypertrophy of the left ventricle. He stresses that he does not in this article refer to the form of "sinistocardigram" (usually with negative T₂) which is due to a horizontal position of the heart. Attention is called to the fundamental difference between the absence of the initial positive deflection in CF₂ in bundle-branch block, or pronounced left preponderance, and in anterior wall infarction; in the first there is a diminution of the R wave, eventually a complete absence, in the last an initial negative deflection (a Q wave) simultaneously with complete or partial disappearance of the R wave. An eventual remnant of the R wave in left bundle-branch block will thus manifest itself as a slight initial positive deflection, in anterior infarction as a splitting in an initial negative deflection.

Inhibition of Bone Marrow Due to Splenomegaly.—Schousboe says that his cases of lymphogranulomatosis and Banti's disease showed splenogenic inhibition of transmission of cells from the bone marrow similar to that described in cases of tuberculous splenomegaly. The proliferation of the reticulo-endothelial elements in the spleen is assumed to cause characteristic relations of the blood and bone marrow, mainly anemia, thrombopenia, leukopenia, hyperplasia of the bone marrow and shifting to the left, which after splenectomy are replaced by normal hematologic relations.

OBSTETRIC SHOCK: ITS CAUSES, RECOGNITION AND MANAGEMENT

CHAIRMAN'S ADDRESS

HARVEY B. MATTHEWS, M.D.
BROOKLYN

Shock or its equivalent, by whatever name the era in question gave it, has been known since man came on the earth. Primitive men and women, in their struggle for existence, survived or died of shock from injury, trauma, hemorrhage and sickness. Hippocrates undoubtedly gave admonitions about the "bodily ailment" that we know as shock and called attention to the facial expression—the hippocratic facies—observed in those dying of cholera, which is a typical example of medical shock and differs in no wise from surgical shock save in etiology. And similarly, the pathologic lesion of shock and allied states, although not designated by the term "shock" until during the eighteenth century, can be traced down to the present era.

In 1568 William Clowes recognized shock and attributed it "to the presence of a foreign body in the wound or in the blood." John Hunter in 1784 wrote concerning the shock syndrome and its relation to surgery. However, it was not until 1795 that James Latta, writing on surgical shock, actually used the word "shock," as we know it today. Sir Astley Cooper in 1836 published a written report of a number of cases of shock, with pertinent comments on the effect of shock on the nervous system.¹

In 1870 Goltz of Strasbourg performed his classic experiments on the frog, which formed the basis of our modern conception of shock. Since the time of Goltz many research workers, both competent and incompetent, in "good, bad and indifferent" laboratories, have written a voluminous literature on various aspects of shock. In their enthusiasm to solve this perplexing problem, many physiologists and surgeons have published data and drawn conclusions from them which have not stood the test of time and experience and hence have had to be discarded. However, there remains available today a great mass of reliable information on shock, compiled largely since the World War, where, through the cooperation of American, British and French surgeons and physiologists, the real foundation of our present day concepts of the shock syndrome was laid.² Yet, with it all, the subject of shock is still in a

state of more or less confusion in the minds of most physicians. It is because of this state of affairs and because I hope to arouse or rekindle interest that I have presumed to address this audience on the subject of obstetric shock, realizing full well that I shall add nothing to the sum total of information already available.

At the outset of the discussion which is to follow it would seem in order to have an acceptable definition of shock. Of the many definitions that have been offered, Moon³ comes nearest to conveying the correct conception of shock. It is as follows: "Shock is a circulatory deficiency, neither cardiac nor vasomotor in origin, characterized by decreased blood volume, decreased cardiac output (reduced volume flow) and by increased concentration of the blood."

Shock can truthfully be considered one of the most confusing syndromes encountered by the clinician in all branches of medicine. This syndrome is recognized to be a group of symptoms and not a disease, and whenever it occurs is a serious and often fatal condition characterized by vasomotor collapse, drop in blood pressure and consequent failure of the circulation. In shock the impairment of the circulation results in a stasis of the blood in the capillaries, transudation of plasma into the tissue spaces, deficient oxygenation of tissues and diminution of blood volume. The heart in shock is well able to perform its function. However, the physical and physiochemical changes will eventually cause impairment because of the extra strain placed on it by its endeavor to overcome the deficient circulation. Weakness of the heart beat is due to reduced inflow from the veins and not to an essential cardiac deficiency.

In spite of the enormous amount of research on the subject of shock, the causes for the disturbance in circulatory function are still unknown. Many theories have been advanced as to the cause of shock, but no uniformity of opinion exists as to its production. The following course of events seems to be accepted by all investigators: The heart is not primarily at fault and the disturbance does not originate in the nervous mechanism controlling it or in the vasomotor system. A marked decrease in the total blood volume and an increase in concentration of the blood have been constant manifestations. The latter feature appears early, is easily detected and hence is useful as a criterion of shock, whether this occurs clinically or is produced experimentally. The substitution of hemoconcentration as a diagnostic aid, instead of changes in blood pressure as a criterion, facilitates the early recognition of shock and permits of a distinction between the effects of narcosis, hemorrhage or injury. The volume output of the heart per minute, or, as is so often stated, the volume flow of arterial blood, is markedly decreased. This feature

Read before the Section on Obstetrics and Gynecology at the Ninetieth Annual Session of the American Medical Association, St. Louis, May 18, 1939.

is technically more difficult to demonstrate and, consequently, not so many workers have emphasized it.

Clinicians agree on the signs of shock. They are as follows: Prostration is evident; the patient is profoundly depressed, weak and restless. The pulse is rapid, feeble and of small volume. The extremities are cold and the body temperature is low. The face is drawn, ashen or livid in color, anxious in expression and moist with cold sweat. The eyes are sunken and surrounded by bluish rings, producing the classic "hippocratic facies." Thirst is incessant, but attempts to relieve it are ineffective because of vomiting. The fluid vomited is often in excess of that swallowed and contains small brown flocculi. Perspiration is profuse and diarrhea may be present. The respirations are shallow and interspersed with deep sighs. The blood pressure declines progressively. Urination is scanty or suppressed. Consciousness is retained until finally there is loss of sensitivity, of responsiveness to stimuli and of reflexes. Unconsciousness or coma precedes death. It should be noted that sometimes a marked and rapid increase in temperature—agonal fever—precedes death.

For the successful treatment of shock, the physician should not wait for the development of this clinical picture. Watchful waiting during this period is disastrous. The time will be short for the systemic deficiency of oxygen to produce irreversible changes in the capillaries, in the myocardium and in the delicate cells of the central nervous system. Treatment, to be effective, must precede the development of the clinical manifestations described. It must anticipate the complicated interplay of the varied group of agencies whose combined efforts culminate in failure of the circulation. This vicious circle with its contributory factors requires time for development. When capillary relaxation begins and the sequence which may lead to shock is initiated, the disturbance is compensated for a time. This is accomplished in part by constriction of the arteries and by the discharge of blood into the circulation from the spleen and other reservoirs. Further compensation is accomplished by restricting the circulation to vital organs. This period of compensated circulation lasts for an indefinite time, during which the total blood volume and volume flow of blood are reduced but adequate blood pressure is maintained. Gradually, as time passes, the compensation fails, the blood pressure drops progressively and the clinical signs become unmistakable. A grave error is made by those who depend entirely on blood pressure as an indicator of the condition of the circulation. A marked decline in pressure never occurs early and often appears in the terminal state. Low blood pressure is not a sign of developing shock but of decompensation. There is abundant clinical and experimental evidence to support these statements.

Those who have studied shock by various means have disagreed on many points, but there is complete agreement that a marked decrease in the total blood volume is a prime factor. For many years the "problem of the lost blood" was the chief enigma of shock. One of the facts established early in the World War by clinical studies on wounded men was that the blood became progressively more and more concentrated as shock developed. But the relationship of hemoconcentration to the lowered blood volume may be due to decrease in volume of corpuscles or of plasma or both. Immediately after a large hemorrhage the blood volume is decreased as a result of the loss of blood cells and plasma. In shock there is a marked decrease in total blood volume. This is due to a decrease in plasma

volume because of the transudation of fluid and protein through abnormally permeable capillaries. This results in a state of hemoconcentration, as evidenced by hematocrit values and red blood cell counts. Hemoconcentration furnishes a practical means of differentiating shock from hemorrhage.

Variations in blood volume of practical value in determining the state of the circulation have been found after severe wounds (Keith), but estimations of blood volume are not sufficiently simple for clinical use. Variations in volume flow are equally significant, but these are even more difficult to determine clinically. Hemoconcentration appears early, is regularly present, progresses in a degree paralleling that of the circulatory deficiency and is detectable by simple means—repeated red blood cell counts. It is also recognized by variations either in hematocrit readings or in the specific gravity of the blood, in the hemoglobin content or in the erythrocyte count. The latter is the simplest and most accurate of the four. Marked variations in hematocrit readings may result from swelling of the individual red blood corpuscles when no loss of plasma has occurred by leakage. For this reason the readings may give misleading information. Few physicians are prepared to determine the specific gravity even by the simple method of Hammerschlag. The variations in specific gravity do not occur in so wide a range as those of the erythrocyte counts. For example, the former may range between 1.050 and 1.070, while counts on the same blood would show an increase from 4,800,000 to 9,000,000 red blood cells.

On theoretical grounds the hemoglobin content should run parallel with the red blood cell count and should be equally accurate. Practically there are fluctuations in the hemoglobin readings by which they vary from the counts of erythrocytes made on the same samples of blood. Why these variations occur and whether they are related to the anoxemia present in shock is not known. The progressive increase in the number of red blood cells presents a curve which has fewer irregularities than that of the hemoglobin content. Hemoconcentration invariably develops before the blood pressure declines.

Other clinical signs may be noted during the early stages of shock. Eppinger emphasized the empty, flaccid condition of the superficial veins. Several authors have recorded that it is difficult sometimes to secure blood by venipuncture. The skin and subcutaneous tissues lose their normal tonus and become flaccid or doughy in consistency. The skin becomes pale and does not bleed when punctured. The pulse may be normal in rate but low in volume. This change in quality is readily detected by an experienced clinician. It indicates a decrease in the volume flow and occurs before the arterial pressure is reduced. All these signs indicate a reduced volume flow of blood and they occur while the mechanism of compensation is still effective. The presence of these signs combined with a hemoconcentration of 25 per cent or more is ominous. If the deficiency progresses, decompensation occurs rapidly and an unremitting decline in blood pressure is imminent.

Comparison of blood pressure and hemoconcentration curves in cases of imminent circulatory failure reveals a strikingly early appearance of hemoconcentration and a relatively late decline in blood pressure. It is evident, therefore, that hemoconcentration is the earliest detectable sign of shock and can be determined by any physician capable of doing red blood cell counts.

OBSTETRIC SHOCK

"Shock is shock," and that occurring in obstetrics, so far as can be determined, is no different from surgical, medical or experimental shock. Furthermore, its recognition and treatment present the same identical problem as other types of shock. In recent years there has appeared, particularly among the French and German observers, the idea that the mechanism of the production of obstetric shock is different from other varieties of shock; but the preponderance of evidence is still against such a view.

Besides the changes which take place in the pelvic structures as a result of pregnancy, there are changes in the blood circulation, respiratory system, urinary tract, alimentary tract, osseous system, ductless glands and metabolism. For practical considerations, in the mechanism of the production of obstetric shock it is desirable to possess an accurate knowledge of the physiologic changes of pregnancy. These changes may predispose to shock and shocklike conditions in the presence of moderate hemorrhage, trauma, anesthesia and infection. For obvious reasons, I could not include in this discussion the physiology of pregnancy. However, its importance must again be emphasized.

It is apparent that, from the physiologic changes coincident with pregnancy, the parturient is a poor surgical risk, since even moderate hemorrhage, trauma, anesthesia or infection may produce shock. Further, the hypersensitive nervous system predisposes the patient to reflex shock. Prolonged labor with associated dehydration and acidosis are factors resulting in toxic shock. The hypersensitivity of pituitary extract of the expectant mother is another etiologic factor. The toxemias of pregnancy, with unrecognized or demonstrable liver damage, are predisposing factors and often lead to fatalities which can be explained only at necropsy. Since the uterine veins have no valves and the placental site contains numerous blood sinuses, thrombosis and embolism are not uncommon, especially after prolonged labor with a poorly contracting uterus. Unrecognized cardiac lesions, thyroid disease, tuberculosis and adrenal cortical insufficiency may, after prolonged labor, suddenly present a shocklike picture.

Obstetric trauma, as a rule, is associated with moderate hemorrhage. Shock is characterized by paralysis of the splanchnic vasomotor system with venous stasis in the abdominal cavity. When shock is associated with hemorrhage, the severity of the symptoms is out of all proportion to the severity of the hemorrhage, which may be relative. Hemorrhage does not, per se, induce shock, but the combination of hemorrhage and trauma may produce shock when neither the hemorrhage alone nor the trauma alone would have this effect.

Acute traumatic lesions, like ruptured uterus or extensive lacerations of the cervix, with moderate or profuse hemorrhage, following instrumental or spontaneous delivery, are always productive of shock. Obstetric hemorrhages are always alarming, and in most cases the clinical picture is evident and the diagnosis is readily made.

TREATMENT

The best treatment for shock is prevention. All hemorrhage should, of course, be promptly controlled. The probable or possible development of shock can be anticipated by any physician who is conversant with the various conditions which may cause it. At times it may be possible to obviate the cause; otherwise measures should be directed toward preventing or minimizing any degree of circulatory inefficiency. Any therapeutic agent

available for use as a preventive measure is worthy of serious consideration. Dextrose is such an agent and has been spoken of as the "universal therapeutic agent," for it has many and varied uses in general medicine, surgery, pediatrics and obstetrics and gynecology. In obstetrics, however, it is especially valuable because, as the physiologists tell us, among other important therapeutic properties it is a food for all the vital organs, particularly the liver and the heart muscle; it requires no digestive processes to prepare it for absorption: being a monosaccharide, it is spontaneously and completely metabolized to carbon dioxide and water; it promotes diuresis and combats acidosis, and it temporarily raises the systolic blood pressure and improves the quality and reduces the rate of the pulse. It follows, therefore, that dextrose may be used equally well prophylactically to prevent shock or therapeutically during shock.

Prolonged labor produces muscle fatigue, which is shown by the gradual increase in pulse rate, slowing of uterine contractions, tendency of the tongue to become dry, intestinal distention, and usually some rise in temperature. The tired parturient patient is a poor operative risk. Furthermore, anesthesia upsets the balance between the constituents of the protein radical, which has already been disturbed by the pregnancy. In such cases a dose of morphine secures both physical and uterine rest, and an intravenous injection of from 100 to 200 cc. of a 50 per cent dextrose solution will completely change the patient's appearance, as the pulse is slowed and both the systolic and pulse pressures are improved. If fluid is needed, 75 Gm. of dextrose in 500 cc. of saline solution may be given from 3 to 5 cc. per minute.

The effects of general anesthesia as contributory to shock are well known. Severe physical injury may be sustained without apparent evidence of circulatory deficiency; but with anesthesia, or during an operation, shock may develop. A similar effect may result from disease which has reduced the patient's reserve of physiologic resources. Surgeons widely hesitate to subject a patient who is a "poor surgical risk" to general anesthesia and extensive operative procedures. Experience indicates that nitrous oxide anesthesia is less likely to precipitate shock than either ether or chloroform. Local infiltration anesthesia is the safest and has been extensively employed with much success in operative obstetrics.

Recently the barbiturates have been advocated as more satisfactory than ether, and they have been widely advertised as minimizing the danger of shock in obstetric cases. Such claims must be viewed conservatively. The use of the barbiturates as anesthesia during the production of shock experimentally indicates, in the dosage used, that they contribute greatly to its development. The occasional reports in articles on surgical and obstetric practice of untoward results under barbiturate anesthesia confirm the opinion that these compounds are not free from danger.

Prophylaxis, therefore, is a bulwark against shock or conditions leading to shock, that every physician doing obstetrics should appreciate more keenly than has hitherto been done; for no pathologic lesion in obstetrics more accurately dovetails in with the old adage that "An ounce of prevention is worth a pound of cure" than that of shock.

For many years physicians have noted the weak pulse, low blood pressure and other evidences of failing circulation in shock. Long ago it was demonstrated that this

deficiency is not of cardiac origin, and that fact has been verified repeatedly, both clinically and experimentally. Notwithstanding this knowledge, many still attempt to secure slower, stronger pulse and improved heart action by digitalization of patients who are shocked and moribund. Such attempts show a simple childlike faith in the omnipotence of drugs. Equally illogical is the attempted treatment of shock with vasoconstrictor drugs such as epinephrine. Apparently, some have not sensed that in shock the arteries are not relaxed but are markedly contracted. But the reasoning is simple: these patients have low blood pressure, epinephrine increases the blood pressure in normal subjects, therefore give epinephrine. Not only is this agent useless; it has grave potentialities if given in excess of physiologic doses. Shock can be produced in normal animals by the prolonged effects of epinephrine. The use of such drugs as digitalis and epinephrine in cases of shock might not be censured so severely if occasional success resulted. But one searches in vain for published reports of beneficial effects from the use of these drugs in shock.

Evidence has been presented indicating that adrenal cortical extract, given by injection, aids in preventing shock. It is probable that in some apparently normal persons the adrenal cortical function is slightly below normal. Perhaps those who are hypersensitive to injuries, infections and drugs belong to this group. If so, it is possible that the substance of adrenal cortex supplied artificially might tend to prevent the development of shock when these persons are passing through emergencies.

The use of pitressin has been suggested because of its effects in producing contraction of the capillaries. It is recalled that Krogh's experiments indicated that a hormone of pituitary origin is a physiologic agent causing contraction of the capillaries. On theoretical grounds such a substance might be useful in restoring normal tonus to capillary endothelium which has become relaxed, provided the endothelium has retained its capacity to respond to such stimuli. In many instances it fails to accomplish this end.

Morphine, in sufficient dosage, should be used in shock to relieve pain and allay restlessness. If bleeding is or has recently been present, it should be given to quiet the circulation. When marked cyanosis is present, some sedative other than morphine, for obvious reasons, is indicated.

Many writers have advocated the use of caffeine, and a few believe that strychnine is beneficial. It is uncertain whether these suggestions are based on sound experience or on theory. It has not been shown that either of these agents influences capillary tonus directly. Under conditions of warfare, hot coffee and tea were used with benefit in preparing men suffering from wounds, cold and exhaustion for operation. It is believed that this is the logical use of stimulants. One would not expect them to produce lasting improvement in the failing circulation of shock.

Various mechanical means for aiding the return of venous blood have been employed. The most common of these is the Trendelenburg position. Other efforts advised consist in mechanical pressure applied to the limbs, such as an elastic binder, and sand bags to the abdomen. These suggestions recognize the factor of low venous pressure and they attempt to raise it by external pressure. The reasoning on which such suggestions are based is not entirely sound and does not take into account the fact that blood is not pooled in the veins but in the capillaries. The effect of gravity, when the

body is in the Trendelenburg position, favors recovery from "primary shock" or syncope but is of very doubtful value in late shock. Blood sequestered by stasis in the visceral capillaries is not readily affected either by gravity or by external pressure. Furthermore, a very important feature is stasis of blood in the pulmonary circulation. This cannot be beneficially affected by these methods either. Sand bags to the abdomen have the disadvantage of hindering respiration. Any condition that limits respiratory activity lessens the delivery of oxygen and accelerates the development of shock. Mechanical aids to combat the effects of low venous pressure are therefore of doubtful value.

Heat should be employed externally in every case of shock in an effort to improve peripheral circulation. No patient in shock can be successfully treated unless body temperature can be raised to within normal or nearly normal levels. Excessive heat, on the other hand, is contraindicated because it causes a loss of water and chlorides as the result of sweating.

Loss of blood volume and the disparity between it and the volume capacity of the vascular system are basic factors in the mechanism of shock. The restoration of blood volume is a most logical and beneficial measure. When the permeability of the capillaries has not been increased, the loss of fluid may be made up and the circulatory efficiency restored by introducing saline solution. Low blood volume due to hemorrhage may be effectively restored by this means alone, provided the total hemoglobin has not been reduced below one third of that normally present. In dealing with shock and hemorrhage, Keith found that patients fell into one of three groups, according to their response to fluids introduced into the vascular system:

1. Those whose blood volume had been moderately reduced but whose vascular systems could both absorb and retain fluid. These would recover spontaneously if given fluid by mouth or otherwise.

2. Those with more serious loss of blood volume and with marked loss of plasma (hemoconcentration), whose vascular systems had lost the ability to absorb fluid but would still retain it if supplied in suitable form. Treatment of these, by infusion of gum-saline solution or by transfusion of blood was effective. They were spoken of as partially decompensated cases.

3. Those with marked loss of plasma volume, whose vascular systems would neither absorb nor retain fluid. The blood pressure in this group had already been below the critical level (80/40) for some time. No form of treatment was effective in these decompensated cases.

From extensive laboratory and clinical research, it is known that the ideal intravenous solution in the treatment of shock and its allied conditions should act: (1) to increase blood volume in the cardiovascular system without overloading the heart; (2) to provide easily accessible nourishment for the tired out myocardium and liver, i.e., replacement of glycogen in these organs; (3) to help restore the circulation in general, and (4) to tide the patient over the critical period of shock, dehydration and acidosis, profound toxemias and critical infections until transfusion and other suitable therapeutic measures can be instituted. Furthermore, it would seem that the intravenous addition of large quantities of fluid of any nature, except blood perhaps, is inadvisable and often actually dangerous, for it might well mean the addition of an insurmountable load on an already impaired circulation and weakened myocardium, which might result in cardiac dilatation and failure.

The ideal method of treatment is to introduce some fluid into the blood stream that will cause an increase both in blood volume and in blood pressure. To accomplish this result, blood and its substitutes have been successfully employed. Whole blood is the ideal therapeutic agent for increasing the blood volume and blood pressure. It is universally agreed, therefore, that the best method of treating shock due to hemorrhage is by transfusion of whole blood. When whole blood is used, there is a dilution of red blood cells in the blood stream due to the passage of fluid from the tissue spaces back into the blood vessels. Whole blood, therefore, will increase blood volume, although, when injected intravenously in the presence of circulatory stasis, protein is lost through the capillary walls. This, however, is at least partially compensated for, as a large amount of additional protein is being put into the circulation by the intravenous injection of blood.

As an emergency measure, in the absence of blood or because of delay in obtaining the proper donor, it is usually necessary to use a substitute for blood in order to tide the patient over this critical waiting period. The results following the use of most of the substitutes have not been very encouraging. Isotonic saline solution has been shown to be of little practical value. It will temporarily cause an increase in blood pressure, but, as the fluid injected passes into the tissue spaces, the blood pressure will in a very short time be as low as before and usually lower. Besides, with the injection of physiologic solution of sodium chloride there is a decrease in the total amount of plasma and at the same time a decrease in the percentage of protein in a unit volume of plasma. Therefore, isotonic saline solution will not cause an increase in the volume of blood in circulation because, with the diminished osmotic pressure, a decreased quantity of fluid is attracted back into the blood vessels from the tissue spaces. Weak solutions of dextrose have proved to be no more efficient. Solutions of acacia and of acacia with dextrose have their adherents. Acacia was added to saline solution in order to supply a colloid substance which would be retained by damaged endothelium. Later, acacia (6 per cent) was added to hypertonic dextrose solution and this method was successful in temporarily combating shock until transfusion could be given. Other agents that have been used are 2.5 per cent gelatin, human ascitic fluid and preserved human blood plasma.

Fearing the use of large quantities of fluid intravenously in "shocked cases," my associates and I have used in our clinic from 50 to 200 cc. of a 50 per cent solution of dextrose (usually 100 cc.) with excellent results. In cases in which acute shock was not the primary indication for the use of dextrose, 300 cc. of a 25 per cent solution in saline solution has been employed. Some patients have received these injections of dextrose before and after operation and during labor merely as a prophylactic measure, while others have received them for postoperative and postpartum complications. Hypodermoclysis of physiologic solution of sodium chloride is usually given immediately following the intravenous dextrose in sufficient quantity to supply the required fluid (water); i.e., from 2,000 to 5,000 cc. in twenty-four hours.

In cases of acute antepartum hemorrhage (ablatio placentae, placenta praevia), abortion, postpartum hemorrhage and tragic ectopic gestation, the introduction of 100 cc. of a 50 per cent solution of dextrose will raise the blood pressure from 20 to 50 mm. of mercury within a period of five to ten minutes. This

rise is maintained from twenty to forty-five minutes, which gives sufficient time to prepare for transfusion.

Anoxia in the blood and tissues is a factor of the utmost gravity in the operation of the vicious circle of shock. Oxygen by inhalation is indicated and should be employed, I believe, in conjunction with other means more often than it is by most obstetricians. It helps to counteract anoxia before the circulatory deficiency becomes irreversible. This should be done early if benefit is to be expected. The use of oxygen after the blood pressure has declined seriously and the patient is obviously in a critical state will be as futile as its use in the terminal stage of pneumonia.

SUMMARY

Obstetric shock is no different from other types of shock, but the obstetric patient is more susceptible to shock, as a result of mild trauma, hemorrhage and infection, because of the physiologic changes coincident with pregnancy, labor and the postpartum period.

Until better measures are found, efforts to prevent or combat shock must continue along the following primary principles:

A thorough comprehension of the conditions which may lead to shock, and their prevention when possible.

A knowledge of the physiologic changes of pregnancy which predispose the parturient as a poor risk for operative procedures:

The recognition of circulatory deficiency before it is fully developed. Hemoconcentration provides the criterion and repeated red blood cell counts substantiate the evidence.

Efforts to counteract diminished blood volume should be employed before it is too late. Fluids by whatever route should be given. Transfusions should be given early. In the acute hemorrhages in obstetrics, from 500 to 2,000 cc. of blood may be required. In toxic or reflex shock, intravenous administration of hypertonic dextrose solution and salt solution should be given early, blood transfusion only if necessary.

Efforts should be employed to counteract anoxia by the artificial administration of oxygen.

The use of stimulating drugs is of very questionable value.

The use of adrenal cortex extract may be of value as a preventive. This is of unquestionable value when cortical function is known to be deficient.

Active treatment for shock should be instituted early, before complete circulatory collapse results.

In conclusion, I should like to leave this thought: Real progress in the prevention, recognition and management of shock lies not only in cultivating the art of obstetrics but in the study of the biologic principles that concern reproduction, function, nutrition, metabolism and the repair of tissues and in the thoughtful application of this knowledge. With the mastery of these principles, clinical experience and the maturity of years will give that degree of sound judgment which every physician doing obstetrics—general practitioner or specialist—longs to attain.

643 St. Marks Avenue.

Practical and Scientific Medicine.—The divergences between practical and scientific medicine, and especially between their manner of thought and standard of accuracy, are in actual fact profound and far-reaching. They are perhaps as profound as, they are certainly not dissimilar to, those exhibited in the past between orthodox religion and science.—Lewis, Sir Thomas: *Research in Medicine and Other Addresses*, London, H. K. Lewis & Co., Ltd., 1939.

THE IMPORTANCE OF CANCER AS A CAUSE OF CHRONIC DYSPEPSIA

ANDREW B. RIVERS, M.D.

ROCHESTER, MINN.

Dyspepsia is one of the most frequent causes of man's unhappiness. Dispensers of nostrums, well aware of this fact, are growing rich from the sale of injudiciously recommended medications which allegedly return such sufferers surely and promptly to gastronomic happiness. Persons with chronic dyspepsia who inadvertently persist in self treatment or who continue to apply therapeutic measures advised by nonprofessional medicine venders, despite continuation of symptoms, may be carrying on a dangerous experiment. Not infrequently, such patients are eventually found to harbor diseases which could have been cured if diagnosed earlier. Failure to recognize gallstones or peptic ulcer as the cause of a patient's complaint is a lamentable error; failure to detect the presence of a cancer is fatal to the life of the person who harbors such a lesion. There are some instances in which mistaken diagnoses, although prolonging the patient's suffering, do not seriously jeopardize life. Not so if the offending disease happens to be cancer. Cancer is a relentless invader which persists in its destructive march until it has destroyed the life of its host. To be dealt with successfully it must be detected and destroyed. The earlier it is discovered, the better the chance, as a rule, of the patient's survival.

The object of the study reported in this paper was to gather some information relative to the frequency with which cancer is found to be the cause of indigestion.

MATERIAL FOR STUDY

The total number of cases included in this investigation is 4,656. These were taken in consecutive order from the files of the clinic, the sole criterion for this selection being that these patients included indigestion among their complaints. The diagnoses in these instances were reached after careful clinical and laboratory investigations had been made. These usually included roentgenologic investigations of the gastrointestinal tract or of the gallbladder. In a number of instances the diagnoses were corroborated at operation and in some at necropsy. On the assumption that the relative frequency with which cancer causes indigestion must vary considerably at different ages, the series of cases was then divided into three age groups, which were studied separately. The first consisted of patients from 15 to 24 years of age, the second patients from 25 to 39 years of age, and the third patients 40 years of age and older. When it became evident that cancer was the cause of indigestion among a surprisingly large number of patients in the oldest age group, it became obvious that satisfactory scrutiny would require more accurate study.

Accordingly, the group of patients 40 years of age and older was subdivided into groups comprising periods of five years each, according to ages 40 to 44, 45 to 49 and so on. When this subdivision was made it was found that the number of patients in the older

age groups was too small for drawing accurate conclusions. Thus, these lists were augmented to numbers which seemed adequate simply by adding more histories of patients who complained primarily of dyspepsia, taken from the files in consecutive order. Of these patients, 2,448 came to the clinic primarily because of indigestion. There were 2,208 patients who presented themselves for examination for other causes, including indigestion as one of their minor difficulties. The incidence of cancer in this group was ascertained. It was found that, even among those patients who considered their indigestion of secondary importance, cancer was found to be the cause of their digestive disturbances in 2 per cent of cases.

The following statistical studies are the result of closer investigation of the incidence of cancer among the patients who considered chronic indigestion their major symptom and who came to the clinic because of this complaint.

CANCER AS THE CAUSE OF DYSPEPSIA AMONG PATIENTS BETWEEN THE AGES OF FIFTEEN AND TWENTY-FOUR YEARS

A review of the literature might tend to produce an erroneous impression relative to the frequency with which cancer causes indigestion among young persons. Isolated reports of cases focus attention on the unusual case, frequently leaving impressions which are not correct. Careful review of the histories of patients included in this group disclosed the fact that cancer was the cause of indigestion between the ages of 15 and 24 years in only 0.7 per cent of instances. Although, admittedly, cancer of the stomach occasionally occurs in persons who as yet have not reached the age of 25 years, our total series of 4,656 patients who complained of dyspepsia did not include one such instance. Among the young men of this group there was one instance of cancer of the sigmoid and one of cancer of the testicle with metastasis to abdominal organs. The presenting complaint in both of these cases was chronic dyspepsia.

CANCER AS THE CAUSE OF DYSPEPSIA AMONG PATIENTS BETWEEN THE AGES OF TWENTY- FIVE AND THIRTY-NINE YEARS

Although still relatively uncommon among patients of the age group 25-39, cancer begins to have a role of some importance among the causes of indigestion. In 2.7 per cent of these cases it was assumed that cancer was responsible for indigestion. Among the men included in this group it was discovered that 3.5 per cent were suffering from cancer. The lesion most frequently found was cancer of the stomach. Next in numerical importance was carcinoma of the colon. Included in this group there was one case of carcinoma of the prostate gland with metastasis, one of abdominal carcinomatosis in which the site of the primary lesion was not determined, and one of carcinoma of the testis with metastasis. In all of these instances the primary reason for their examination was indigestion.

That cancer of the stomach must be a rather rare disease among women less than 40 years of age is suggested by the fact that there was no instance of cancer of the stomach among 436 women in this age group. Among the causes of indigestion which brought the women of this age group to the clinic for examination there was one instance of cancer of the colon, one of retroperitoneal cancer, one of pelvic cancer with metastasis and one of abdominal carcinomatosis.

CANCER AS A CAUSE OF DYSPEPSIA AMONG
PATIENTS FORTY YEARS OF AGE
AND OLDER

In chart 1 is indicated by an incidence curve the frequency of cancer among 2,448 patients 15 years of age and older, all of whom had presented themselves at the clinic for diagnosis or treatment because of chronic dyspepsia. Patients who are 40 years of age or older are arranged according to periods of five years. It is interesting to note that among the patients included in this series indigestion was caused by carcinoma more than twice as frequently among patients in the late forties as among those in the early forties. For the next five years there was then but little relative increase in the incidence of cancer as the cause of dyspepsia among these patients. In the late fifties 12 per cent of these patients were found to have cancer. The relative frequency of cancer as the cause of indigestion among patients 60 years of age or older readily becomes apparent when one considers that, from the age of 60 to 64 years 21.5 per cent, and from the age of 65 to 69 years, 31 per cent were found to be suffering with this disease. To assume that an elderly patient of 70

Chart 1.—Incidence of cancer as a cause of indigestion according to age.

years or older who complains of repeatedly recurring dyspepsia is suffering from some unimportant condition is hazardous in the extreme. In 44 per cent of such patients the presence of cancer was demonstrated. After noting the surprisingly high incidence of cancer in this age group it was thought important to know whether men and women who presented themselves complaining of chronic indigestion were equally likely to harbor malignant disease.

CANCER AS A CAUSE OF INDIGESTION AMONG
WOMEN FORTY YEARS OF AGE AND OLDER

In chart 2 is illustrated the incidence of carcinoma as the cause of indigestion among 638 women, arranged according to age in groups of five years each, beginning at the age of 40 years. Additionally, in each column will be found the site of the malignant lesions responsible for dyspepsia in the respective age group.

In evaluating the cause of dyspepsia in a large series of cases it will be found that cancer is the cause of such symptoms with much more frequency among males than among females. This is not true, however, in this series among patients between the ages of 40 and 44 years. Women of this age group whose salient complaint was of indigestion were found to have cancer slightly more frequently than were the men of this age

group. Between 45 and 49 years of age 7.9 per cent of women who complained primarily of recurring indigestion were found to have cancer. Interestingly, the incidence of cancer as the cause of indigestion among the women included in this series diminished in frequency from the age of 45 years to the age of 65

Chart 2.—Incidence of cancer as a primary cause of indigestion in females according to age and site of lesion.

years; from 45 to 49 years it was 7.9 per cent, from 50 to 54 years 6.8 per cent, from 55 to 59 years 5 per cent, and from 60 to 64 years 4 per cent. After the age of 64 years, however, there was a sharp rise in the importance of cancer as a cause of indigestion among these women. Cancer was found to be the cause of such complaints four times as frequently among women who were in their late sixties as among the women in their early sixties. Among women 70 years of age and older who had come to the clinic primarily because of indigestion, cancer was assumed to be the cause of their difficulties in 30 per cent of cases.

CANCER AS A CAUSE OF INDIGESTION AMONG
MEN FORTY YEARS OF AGE AND OLDER

Chart 3 deals with the incidence of carcinoma as the cause of indigestion among 844 men arranged according to age in groups of five years each, beginning with patients aged 40 years. Additionally, in each column is indicated the site of the malignant lesion responsible for dyspepsias in that age group. The relative fre-

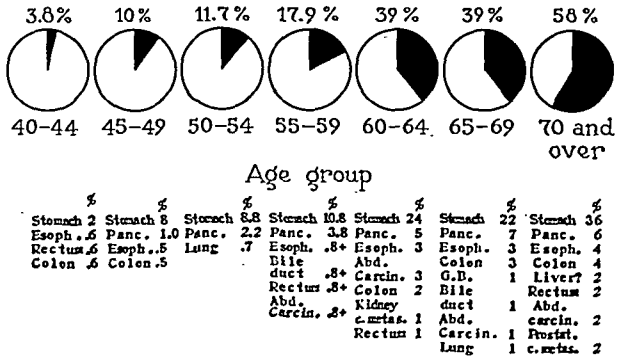

Chart 3.—Incidence of cancer as a primary cause of indigestion in males according to age and site of lesion.

quency of cancer as the cause of indigestion among men in their early forties was not surprisingly high. In this group 3.8 per cent of the men who had presented themselves for examination primarily because of chronic dyspepsia were found to have cancer; between the ages of 45 and 49 years 10 per cent, between 50 and 55 years 11.7 per cent, and between 55 and 59 years 17.9 per cent of males with primary complaints of indigestion

were demonstrated to have cancer which was assumed to cause their symptoms. The seriousness of persisting indigestion among men between the ages 60 and 70 years is demonstrated by the fact that, in 39 per cent of males of this age group whose dyspepsia was serious enough to send them to the clinic for relief, cancer was demonstrated as the cause of this symptom. It is a remarkable fact that, after 70 years of age, 58 per cent of the men included in this series were found to have cancer.

DYSPEPSIA CAUSED BY CANCER OF THE STOMACH

Carcinoma of the stomach was by far the most frequent among the malignant lesions responsible for indigestion. Among the total number of diseases responsible for chronic dyspepsia, cancer remained relatively infrequent as a cause of dyspepsia until patients reached the age of 45 years. Men in the late forties were found to have carcinoma of the stomach as the cause of their indigestion four times as frequently as were men in the early forties.

It is interesting to note that, for a fifteen year age period beginning at the age of 45 years the frequency of cancer of the stomach as the cause of indigestion

Chart 4.—Incidence of cancer as a cause of indigestion according to sex and age. Indigestion was the primary complaint in this group.

among these patients remained comparatively constant. After the age of 60 years, however, there was a rapid increase in the number of instances in which gastric cancer was demonstrable as the cause of indigestion. More than twice as many men in the sixties who sought relief for dyspepsia were found to harbor gastric carcinoma as those in the late fifties who volunteered this complaint.

Carcinoma of the stomach was by far the most frequent among all the causes of indigestion among the men of 60 years and older who came to the clinic because of this complaint. Men beyond the age of 69 years who had chronic dyspepsia were found to have gastric carcinoma in 36 per cent of instances.

A study of the incidence of cancer of the stomach among women who complained of indigestion is of some interest. Throughout this series, cancer is less commonly the cause of indigestion among women than among males. Among men, carcinoma of the stomach gradually became of relatively greater importance among the causes of indigestion in the older age group, whereas it was noted in this series that, from 45 to 65 years of age there was a gradual diminution in gastric carcinoma as the cause of indigestion among the women.

Actually, carcinoma of the stomach was demonstrable as the cause of chronic indigestion in only 2 per cent of women between the ages of 60 and 65 years. Among men of the same age group, gastric carcinoma was responsible for indigestion just twelve times as frequently.

It seemed of some importance that the women in this series who had reached the age of 65 years were six times as likely to have cancer as were women in the early sixties. Women 70 years of age and older who complained primarily of indigestion were found to have cancer of the stomach in 14 per cent of instances.

Cancer of the Esophagus.—Although cancer of the esophagus occurs in women, its rarity as the cause of indigestion in women is attested by the fact that among more than 2,000 women who have chronic dyspepsia included in this series there was no instance of the condition. Among the men included in this study, carcinoma of the esophagus was considered the cause of indigestion in less than 1 per cent of instances before the age of 60 years. Three per cent of the men in their sixties and 4 per cent of the men more than 69 years of age were found to have cancer of the esophagus on consultation at the clinic because of indigestion.

Cancer of the Pancreas.—Among the malignant conditions responsible for indigestion, carcinoma of the pancreas ranks next in numerical importance to carcinoma of the stomach in male patients. In the series under consideration we found no instance of cancer of the pancreas among patients less than 45 years of age. In the late forties, 1 per cent of the men coming to the clinic because of dyspepsia were found to have malignant lesions of the pancreas. From this age to 70 years there was a progressive increase in the relative importance of carcinoma of the pancreas among the causes of indigestion.

Between the ages of 65 and 69 years, 7 per cent of the patients who presented themselves for relief of indigestion were found to be harboring a malignant lesion of the pancreas.

Among the women included in this study, cancer of the pancreas was far less commonly the cause of indigestion than among the men. This series includes 638 women aged 40 years and older who sought relief from dyspepsia. There were among these only two instances of carcinoma of the pancreas; one woman was in the early forties, the other in the early fifties.

Cancer of the Gallbladder and Bile Ducts.—Although malignant disease of the gallbladder and bile ducts must be considered among the causes of indigestion, it is actually one of the less common causes of such symptoms.

These diseases are extremely rare in men. Among 844 men 40 years of age and older who made a primary complaint of indigestion there were two instances of cancer of the bile ducts and one of cancer of the gallbladder.

Among the women of this group there were three instances of cancer of the gallbladder and one of cancer of the bile ducts. Two cancers of the gallbladder and one involving the bile duct occurred in women past the age of 64 years.

Cancers Involving Organs Other Than Those Aforementioned, Responsible for Dyspepsia.—Patients who have carcinomas that involve the colon or rectum occasionally present themselves because of symptoms of dyspepsia. Similarly, cancers of various other organs

such as the uterus, the bladder or the kidney, probably because of metastatic lesions, occasionally produce symptoms of chronic indigestion sufficiently severe to send such patients to their physicians with dyspepsia as their major complaint.

SUMMARY

The interest of medical and social workers pertaining to the crippled child, the tuberculous, the feeble-minded and the epileptic is well known. Even the patients with social diseases have their benefactors. During recent years educational programs have taught the woman who has a mass in her breast and the patient who has an unhealed ulcer to seek the advice of a physician. Altogether too often, however, the patient who perennially complains of dyspepsia is left to follow the advice of a radio announcer or a drug clerk. The youthful sufferer from dyspepsia who allows himself to be treated in this way may do himself no harm, but the man past middle age who is a chronic sufferer from indigestion pursues a dangerous course by following this type of treatment. Chronic dyspepsia in a man who has reached the age of 60 years is a symptom of very grave possibilities. Of the men of this age who came to the clinic because of indigestion, 39 per cent were found to have cancer. In men of 70 years and older, cancer was actually demonstrable as the cause of their dyspepsia in 58 per cent of instances.

A study of the incidence of cancer according to five year age groups makes it possible to construct a picture in serial sections that shows the threat of this disease to the patient who has chronic indigestion. Several interesting trends in the behavior of carcinoma became evident from this study (chart 4). Among men, cancer was almost three times as frequently the cause of indigestion in the late forties as it was in the early forties. From the age of 45 to 55 years the incidence of cancer remained comparatively stationary. In the late fifties there was an appreciable increase in the incidence of carcinoma as the cause of indigestion. The onset of the serious threat of cancer in men, however, occurred at the age of 60 years. This seems definitely to represent the beginning of the cancer age period of the male dyspeptic patient.

Interestingly, this is from five to ten years earlier in life than a similar increase in incidence of cancer as the cause of indigestion among the women included in this series. The incidence of cancer as a cause of indigestion in females was 7.9 per cent between the ages of 45 and 49 years. I was surprised to find a gradual diminution in the relative importance of cancer among the women included in this group until the age of 65 years was reached. Actually, women between the ages of 60 and 64 years were found to have cancer when they presented themselves because of dyspepsia only about half as frequently as did the women in the late forties. After the age of 64 years, however, women seem to enter the dyspepsia-cancer age period. Cancer of the stomach was responsible for indigestion in these female patients six times as frequently between the ages of 65 and 70 years as it was in the early sixties. Women of 70 years and older who came to the clinic because of dyspepsia were found to have cancer in 30 per cent of instances.

The organ most frequently invaded by cancer responsible for dyspepsia was the stomach. Next in order of frequency was the pancreas. Carcinoma of the pancreas is much more frequently found in men than in women. This is true also of carcinoma of the esoph-

agus. Cancer of the liver, gallbladder and biliary duct system was relatively uncommon among the causes of indigestion in this group of patients.

The advisability of continuing the search for cancer, even when this is not demonstrable in the upper portion of the digestive or accessory digestive tract, becomes evident when one considers the variety of sites that harbored such a lesion when the patient's presenting complaint was indigestion. Not only did patients with carcinoma of the colon or rectum present themselves at times because of dyspepsia but also patients who had malignant lesions of the pelvic region or kidney with metastasis to abdominal organs, or to other organs such as the lung, occasionally sought aid because of symptoms attributed by them to digestive disturbances. This series also includes some instances in which patients whose major difficulty was indigestion were found to have widespread abdominal cancer in whom it was impossible or not practical to determine the exact site of the primary lesion.

The importance of investigating the cause of indigestion, even when the complaint is primarily related to some other difficulty, is indicated by the fact that among the 4,656 patients there were 2,208 who presented other complaints primarily and yet, during the course of their examinations, they mentioned the fact that they had experienced some indigestion. Of these, between 2 and 3 per cent were found to have cancer which was considered the cause of the indigestion, which they had considered of minor significance.

CONCLUSIONS

1. Dyspepsia is caused by cancer much more frequently in men than in women.

2. Cancer begins to become a relatively frequent cause of indigestion in both sexes at about the age of 45 years.

3. There is a pronounced increase in the incidence of cancer as the cause of indigestion in later life. In this series, 39 per cent of the men who had a primary complaint of indigestion who were between the ages of 60 and 69 years of age had cancer. Of the men of this group beyond the age of 70 years, 58 per cent were found to have malignant disease. Women between the ages of 65 and 69 years who presented themselves because of dyspepsia had cancer in 16 per cent of cases, and after the age of 70 years in 30 per cent of instances.

4. Men seem to progress into a definite dyspepsia-cancer age from five to ten years earlier in life than the women. This age in men started in the late fifties and in women between the ages of 65 and 70 years. An exhaustive search for cancer should therefore continue in cases in which dyspepsia is the major complaint and when patients have reached the cancer age, even when another less formidable cause for such a symptom has been discovered.

5. It has been shown frequently that physicians treat their own dyspeptic difficulties too lightly. After the age of 45 years such symptoms should be evaluated with meticulous care and this should include roentgenologic investigation. Physicians should apply the same principles to their patients who have chronic complaints that relate to the stomach.

6. It seems to me that an educational program having for its purpose the enlightenment of the public with regard to the hazards of nonprofessional treatment of dyspepsia after the age of 45 years, and particularly

throughout the dyspeptic-cancer age period would produce some highly desirable results. To make people who suffer of persistent dyspepsia at these ages more conscious of the possibilities of cancer would undoubtedly result in the detection of many more cancers than now can be diagnosed; some of these lesions would certainly lend themselves to successful surgical treatment, and thus such a program would result in the saving of some lives.

CANCER OF THE RECTUM IN YOUNG PERSONS

CURTICE ROSSER, M.D.

AND

J. G. KERR, M.D.

DALLAS, TEXAS

Carcinoma has been regarded up to comparatively recent years as a disease limited entirely to middle and later age groups. Collected reports in medical literature before 1900 emphasized the extreme rarity of cancer occurring in the first three decades of life. For example, Gusserow¹ in 1886 reviewed 3,385 cases of cancer including epithelioma and found only two that had originated before the patients were 20 years of age. De LaCamp² was able to find only nineteen cases of carcinoma in persons under 20 years of age in a total group of 9,963 cases recorded previous to 1897. Williams³ reported in 1898 that in a study of 806 patients with carcinoma he found only one under 20 years of age. Later he collected 11,934 cases and reported that less than 1 per cent of the patients were under 30 years of age.

Several reporters since 1910 have called attention to an apparently increasing incidence of carcinoma, more particularly carcinoma of the large intestine, in young persons.

In 1914 Bauer and Bertini⁴ collected twenty-one cases of cancer of the cecum and sigmoid in persons under 26 years of age and observed that less than nine months elapsed from onset to death in nineteen of the cases. In 1923 Phifer⁵ was able to find references to forty-nine cases of cancer of the rectum and sigmoid in children under 20 years of age and reported that twenty-three of twenty-six patients followed up were known to be dead.

Fowler⁶ in 1926 made a study of 112 cases of pathologically proved carcinomas in patients under 26 years of age. The largest group of these was found in the colon and rectum, twenty-one cases, or 18.7 per cent; fourteen, or 12.5 per cent, were in the rectum and rectosigmoid. Of the latter group he reported that twelve were dead, one was alive nine months after operation but with recurrence and one has not been followed. The youngest was 16 years old. The average time from onset of symptoms to operation was ten months. The average time from the onset of symptoms

to death was two years one month. Fifty per cent of the patients with colonic and rectal cancer had lesions in the liver or in distant lymph nodes. Sixty-four per cent had involvement of the neighboring nodes at the time of the operation. He found that the family history was positive for malignant diseases in 20 per cent of the group. In eight cases a palliative colostomy was performed. In four cases the abdomen was closed without surgery; in nine cases resection of some type was performed. Fowler believed that, while the presence or absence of involvement of lymph nodes in rectal carcinoma in the young was without prognostic value, because all his patients with rectal carcinoma died regardless of involvement of the lymph nodes, there is a high percentage of involvement of lymph nodes and the average postoperative life is shorter (16.7 months) than in similar cases in the adult. Colloid cancer occurred in 14.3 per cent.

Fowler's conclusions were that carcinoma is more common in youth than is generally recognized, that heredity is the greatest etiologic factor and that the lack of hyalinization, fibrosis, lymphocytic infiltration and cellular differentiation may be responsible for the increased degree of malignancy of carcinoma in the young.

Rankin and Comfort⁷ in 1929 believed that the incidence of cancer of the rectum in young persons was probably proportionately higher than the incidence of cancer invading all organs of the body in persons of the same age. From 1907 to 1926, 3.8 per cent of all rectal cancers seen at the Mayo Clinic were in persons under 30 years of age. There was no difference in the symptomatology in this group, although the duration of symptoms was two months less. Metastasis was found to occur more frequently, 63 per cent as compared with 46.4 per cent in older age groups. The proportion of carcinomas graded 3 and 4 were relatively higher

TABLE 1.—Cancer in the Young: Under 30 Years

Name	Race and Sex	Age	Duration in Months	Type	Grade	Treatment	Result

tomatology in persons 30 years of age or younger are similar to those in the older age groups, the condition is more malignant and has a poorer prognosis.

Because in our own wards we have observed from year to year an increasing number of young persons with cancer in the rectum, it was decided to analyze a series of 100 consecutive cases of rectal cancer to determine the relative incidence of this disease in persons 35 years of age and under in this vicinity, the grade of malignancy present in younger persons as compared with that in more mature years and such other factors as might enter into the prognosis of the younger age group. In this series, cases of sarcoma and cases in which a complete pathologic study and follow-up had not been made were omitted.

In our series (tables 1 and 2) 2 per cent were 16 years of age, 7 per cent were under 30 and 17 per cent were under 36; eight of the patients under 36 were males, one was a Mexican (the only one of this race in the group) and one was a Negro. Three Negroes were included in the older age group, 4 per cent of the entire series being of this race.

The average duration of symptoms for the younger age group was seven months—a period briefer by more than three months than the average duration of symptoms for rectal cancer. The shortest duration of symptoms was three months, the longest twelve months. It should be explained that in two persons of this group the malignancy had been engrafted on previously benign lesions—a polyp in one and an anal fistula in the other.

10. Hall, Norman, and Bagby, J. W.: Carcinoma in the First Three Decades of Life, J. A. M. A. 110: 703-706 (March 5) 1938.

For this reason the time of onset of the malignant process could not be determined with certainty and these two cases were therefore omitted from the calculation of the average duration of symptoms.

There was one postoperative death in the group of seventeen patients under 36. Seven other patients have died in from eight to twenty months following surgery. These seven patients had demonstrable involvement of the lymph nodes at the time of surgery. Four patients are alive and apparently well for periods longer than two years. Five are living, four of them clinically well, for periods of less than two years; these living and well for periods sufficiently long to offer an encouraging prognosis include a white woman, in whom resection was done at the age of 35—no involvement of the lymph nodes being present—who has survived four and one-half years, a Mexican man of 32 who is well five years after a grade 2 squamous cell cancer of the anus was excised, a drawing of which is reproduced in the accompanying illustration, and two others whose low grade papillary cancers were coagulated two and one-half and two years ago.

While 54 per cent of these seventeen patients are still living, the ultimate prognosis in the five patients surviving for two years or less is not good, as in each the malignancy was found to have extended to lymph nodes or to adjacent tissues at the time of operation.

The two age groups were studied carefully to determine any possible variation in the degree of malignancy, rapidity of extension and other pathologic factors possibly influencing prognosis.

Table 3 is a condensed summary of the results of grading, by Broders' method, the tissue removed from

Postoperative specimen of cancer of the anus of a grade 2 squamous cell type in a man aged 32, a Mexican, with long-standing fistula. The condition is apparently cured.

each tumor. It will be observed that the increased percentage of higher grades which might be expected to occur in the younger age group was not present, there being fewer grade 3 cancers proportionately and more grade 2 cancers than in the older age group. The incidence of extremely benign and extremely malignant growths was about equal. However squa-

mous cell cancer, which is believed to be more amenable to treatment, was present in 0.6 per cent of the younger age group and in 4.8 per cent of the older patients. Moreover, colloid or gelatinous cancer was found to be present in a much higher proportion in younger patients (18.7 per cent) as opposed to 7 per cent for the older age group and 9 per cent for the total series.

Rankin¹¹ stated in 1929 that the incidence of colloid cancer in a ten year period at the Mayo Clinic was practically 5 per cent, although other observers have reported somewhat higher figures, especially if the colon is included. While colloid cancer is usually slow of growth and late to metastasize to the lymph nodes and other organs, it spreads by permeation and may cause extensive thickening of the wall of the affected organ.¹² It is usually difficult to eradicate and the eventual mortality is greater than in other types of carcinoma. The patients in the younger age group whose growth was of the gelatinous type had an average duration of symptoms of eight months, longer than the average for the group, but it was discovered that in each case the regional lymph nodes were already grossly involved or adjacent structures were permeated.

Microscopic gross involvement of adjacent or distant lymph nodes was the most striking characteristic of the cases in the younger age group. In 52 per cent micro-

when young mice were used as subjects, malignant new growths developed at an age which would correspond to youth in man.

Whether the statistical increase in the number of young persons in whom carcinoma develops is real or apparent is at this time a question for speculation. The gradual but constant increase of recognized malignant conditions in persons in the lower age brackets does suggest that etiologic factors are at work which have lowered a former partial immunity of young persons to cancer, especially of the lower part of the intestine. If this increase is not real, it constitutes a sweeping condemnation of earlier diagnostic methods as well as of the former teaching that carcinoma should be considered in a differential diagnosis only when the patient is past middle life.

SUMMARY

It appears that there has been an actual gradual rise in the number of young persons found to have cancer in general and carcinoma of the rectum in particular.

A consecutive series of 100 of our own cases of rectal cancer has been analyzed to determine the relative incidence in persons of early and later life. In the group studied, 7 per cent were under 30 years of age and 17 per cent were under 36, slightly higher figures than those reported by others in even the immediate past.

There was no evidence that the grade of malignancy present in this group was higher in young persons, but colloid cancer was found more frequently and squamous cancer less frequently. The younger group provided better surgical risks, and resection was attempted in a greater number than in older persons.

Since this younger group, in contradistinction to some other published reports, does not show a greater percentage of higher grades of carcinoma, it must be assumed that the earlier spread of the lesion, indicated by shorter than average duration of symptoms and early gross involvement of lymph nodes and neighboring structures, is due to a partial absence of defensive barriers to early spread of the lesions in young persons.

ABSTRACT OF DISCUSSION

ON PAPERS OF DR. RIVERS AND DRs. ROSSER
AND KERR

DR. BURRILL B. CROHN, New York: I fail to gain a great deal from statistical papers on this subject. If one says to a patient, "The mortality in partial gastrectomy is 5 per cent," the patient will respond "Do you think I will be one of the 5 per cent?" That of course is the difficult part of the question to answer. To say that there is a 5 per cent incidence of dyspepsia with carcinoma at 25 years of age is an interesting fact, but its clinical application is very difficult. Isn't it true that the diminished figure one quotes in women as compared with men is due to the rise of other causes for female dyspepsia in the same period? In the years from 45 to 65 there enter into the problem a large number of menopausal symptoms. Wouldn't the great increase in that type of indigestion overbalance the number of carcinomatous cases so as to give a relative depression of the carcinoma cases? Isn't it true that there are several variables which have to be taken into consideration which to a greater or lesser extent invalidate the exact data one gives for the incidence of carcinoma as the cause of indigestion? Has it been your experience that carcinoma diminishes in old age? One sees frequently in statistics the fact that the carcinoma curve rises to the age of 65 or 70 and seems to diminish in the eighth decade. I have wondered whether the diminution is actually or relatively true. It was because of the carcinomata of the rectum in youth that I was impressed to the point of formulating roughly a rule that

TABLE 3.—Cancer in the Young: Grades of Malignancy

Entire group	15%	54%	26%	5%

scopic examination was unnecessary to determine this invasion and in 11.7 per cent there was definite extension to adjacent extrarectal tissues; therefore any difference in prognosis in these groups of cases must be attributed, so far as this series is concerned, to an absence of natural barriers rather than to an inherent higher degree of malignancy.

Theilhaber¹³ in 1914 attributed the local disposition of aging tissue to cancer to diminution of cellular elements and contraction of blood vessels, which is also seen in scars and areas of chronic inflammation.

This theory that senile tissue is more likely to be affected by carcinogenic agents has been offset to a considerable extent by the work of Yamagiwa and Ichikawa¹⁴ at the University of Tokyo in 1916 and by the continuation of their investigations by Murray¹⁵ of the Imperial Cancer Research Fund in London in 1929. They succeeded in producing true cutaneous cancer on the ears of rabbits by applications of crude tar. They found that it was impossible to induce cancer rapidly, repeated applications over a period of months being necessary. The time element, of course, suggests an explanation for the greater occurrence of malignant growths in older persons, but it was also found that, when old mice were subjected to chronic irritations by painting on of tar, carcinoma did not develop more rapidly than in younger mice but rather the reverse;

carcinoma in older people occurred usually in the upper alimentary tract. Did you ever see a carcinoma of the esophagus in any one of 18 or 20, or did you ever see a carcinoma of the tongue in a young person? Carcinoma of the esophagus appears in older persons, of 50 and 60, and carcinoma of the stomach in the middle ages; carcinoma of the colon, particularly the lower part of the colon, and of the rectum is the type of carcinoma to which young people are subject. Carcinoma in young people must be related to polyps and polyposis; partial congenital polyposis is not unusual. One should not trust a biopsy of a polyp; if it is suspected of being malignant, it should be so regarded in spite of negative biopsies. I would ask Drs. Rosser and Kerr whether they changed the technic for the young people and did a more radical operation, in the light of the fact that the mortality is so much higher, or that the incidence of metastases of the rapid downward course is so much more likely to be fast and malignant.

DR. HENRY A. RAFSKY, New York: It is generally recognized that, of all the cancers of the so-called inaccessible sites which cause chronic dyspepsia, cancer of the stomach is by far the most common. Still, according to the Metropolitan Life Insurance Company's bulletin, the annual trend as percentage of the average rate from 1917 to 1935 showed a comparatively larger increase in cancer of the intestine and the largest increase in cancer of the pancreas in white persons. The number of deaths annually from cancer of the pancreas in Negroes was too small to warrant calculation. A survey of these groups showed that there were 9.8 per cent more males than females with cancer of the stomach, 0.3 per cent more men than women with cancer of the pancreas and 2.6 per cent more females than males with cancer of the intestine. Cancer of the stomach showed a progressive increase after 35 and reached its maximum between 65 and 74 years. Notwithstanding statistics, however, we must not allow the age incidence of cancer of the stomach to influence us too strongly in differentiating ulcer and cancer, and antral gastritis and cancer. Furthermore, special methods of examination may be required to make the distinction. Drs. Rosser and Kerr's presentation is of timely interest because many still think that cancer of the rectum is rare in persons below 40. At Lenox Hill Hospital from 1923 to April 1939 9.9 per cent of 131 cases of cancer of the rectum were in patients below 36 and 5.4 per cent in patients of 30 years or less, the youngest being a girl of 18 and a lad of 17. Similar statistics were found in a series of fifty-seven patients below 36 with cancer of the rectum treated at Beth Israel Hospital from 1935 to 1939. Statistics compiled by the Metropolitan Life Insurance Company showed that in individuals who died from cancer of the rectum from 1917 to 1935 between the ages of 25 and 34 the annual trend as percentage of average rate was plus 0.3 per cent in white males and plus 1 per cent in white females, and plus 7.9 per cent in Negro males and minus 0.4 per cent in Negro females. This definitely indicates an annual trend upward. It is true that our diagnostic approach to this problem has undergone a change in recent years, but it is questionable whether this alone entirely explains the increase in cancer of the rectum in young people.

DR. JOHN M. BLACKFORD, Seattle: Dr. Rivers' paper has interested me because of work I did along roughly parallel lines several years ago. I wondered particularly about the possible source of error that Dr. Crohn has drawn attention to. The remarkable drop in the incidence of cancer in women from 45 to 55 seems unexplainable, unless it is explained on the basis that Dr. Crohn has suggested. Several years ago we had occasion to work out the relative incidence of sex by decades as patients come to see us at the Mason Clinic in Seattle. By sampling consecutive thousands of registration, we determined that approximately an equal number of males and of females registered with us; however, between 45 and 55 the number of females is considerably higher than the number of males. Dr. Rivers did not state whether he had made any such correction in his figures; if he has not, his curve will be considerably altered by this fact. In the study of gastric cancer and the relative incidence of lesions of the gastrointestinal tract, we attempted to determine how often we saw gastric ulcer in proportion to gastric cancer in our

clinic. Our records were subsequently compared with those from the Mayo Clinic and we were rather gratified to find that our relative incidence agreed with theirs except that they had a higher percentage of cancer. They had a little more than twice as many cases of cancer of the stomach in proportion to our figures with relation to gastric and duodenal ulcer. We were in almost identical agreement regarding the incidence of gastric and duodenal ulcer. To explain this fact, we all know that some patients wander to Rochester from anywhere in this country after being given a hopeless prognosis at home. I feel, in contrast to Dr. Crohn's remark, that statistics are valuable for two reasons: They give trends and they make us think. It is certainly most important to know the relative incidence of carcinoma as people are getting older, in order to put us on our guard in looking for cancer in the patients who come to see us. Between 25 and 30 per cent of patients give a long standing history of indigestion, with symptoms which may be relieved by alkalis, and a remarkably high percentage of such patients have gastric acidity present and frequently high acidity. A warning should be sounded here that we should not miss the clinical diagnosis of gastric carcinoma because the patient has high acidity.

DR. LOUIS J. HIRSCHMAN, Detroit: The study by Drs. Rosser and Kerr is a mandate to those who are accustomed to examine many patients yearly with symptoms pointing to the lower intestinal tract. We have got to meet with our county and state medical societies and teach them, and our undergraduate and graduate students that there is a cancer age and that the so-called cancer age is getting lower and lower. Every one of us is astounded at the increase in the number of patients suffering from carcinoma of the lower bowel below the age of 45. I teach my students that there are as many instances in persons below 45 as above. It is unfortunate that the young patients with carcinoma of the lower bowel—the youngest I have ever seen is 16—are treated for diarrhea, for colitis or for dysentery, before the thought occurs that an examination of the anus and rectum and colon, first instrumentally and then roentgenologically, is indicated. In my experience, carcinoma in most of these patients in the second and third decades has progressed pathetically far. The diagnosis as a rule is not very difficult. There is one thing that we who see many of these cases should do and that is to spend more time advising those who see them early as to what to look for rather than showing charts and moving pictures of our preferred surgical technic in removing carcinomas. We should stress the point that the younger person must be suspected as well as the older one. We shall thus have done much to assist these young people with carcinoma and much to assist the general man in the diagnosis of malignant conditions of the lower intestinal tract.

DR. ANDREW B. RIVERS, Rochester, Minn.: Dr. Crohn's dislike for statistics is shared by most of us. There is no question, however, that many facts can be established by statistical studies. The statistical method is, in fact, the only method of obtaining certain information which is readily applicable to problems such as those which we have discussed today. The purpose of the survey reported in this paper is to make us more cautious in the evaluation of dyspeptic symptoms in elderly patients. I think that Dr. Rafsky's discussion is very much to the point and I am in entire agreement with him that relaxation of caution regarding the diagnosis of cancer is lamentable. This is particularly true when these patients have reached the dyspepsia-cancer age. I should like to point out again that beyond the age of 60 years, even though other causes for indigestion may have been found, the possibility of cancer must still not be overlooked. Dr. Blackford's comments regarding the difference in the sexes relative to the incidence of cancer are important. I am unable to throw any light on this particular phase of the cancer problem. Women seem definitely less subject to cancer of the upper gastrointestinal tract than do men. This fact should be remembered in attempting to evaluate the cause of dyspepsia in the different sexes.

DR. CURTICE ROSSER, Dallas, Texas: I hope Dr. Crohn was not suggesting that, while statistics do not lie, statistics often do. Certainly the definite trend in the statistics of age

incidence in rectal cancer as given in the literature is impressive, and I was happy to have Dr. Rafsky bring additional support to the observation which we have made that there apparently is a definite, constant, gradual rise in the incidence of cancer of the lower bowel in young individuals and that the rise has been so gradual and so constant as to offset any suggestion that it is fictitious or due to lack of proper diagnosis. Dr. Crohn asks whether our surgical maneuvers are not more radical in young persons. They are more radical, for two reasons: one is that we are tempted by the fact that these patients are usually in good general condition for resection of the lesion, even though metastasis may be present, and we are also more inclined to do an abdominoperineal rather than a perineal excision, because we know they can take it better. Unfortunately, no matter how radical the procedure, the result seems in most cases to be the same.

ARTERIOSCLEROTIC GANGRENE

RELATION OF THE AMPUTATION STUMP TO MORBIDITY AND MORTALITY

FREDERIC W. TAYLOR, M.D.

INDIANAPOLIS

Arteriosclerotic gangrene of the lower extremity is a fairly frequent occurrence in the experience of both physicians and surgeons. The maiming possibilities of such a condition are of course evident. However, the profession as a whole does not fully appreciate the high immediate mortality. Approximately one third of all these patients die during the course of their subsequent amputation.

Because of this seemingly excessive mortality, numerous studies have been made in an attempt to remedy the situation. In institutions giving particular thought and care to the problem the mortality is considerably under that mentioned. For instance, McKittrick¹ reported a mortality approximating 15 per cent. Others² have achieved a mortality of about 20 per cent.

The means by which this reduction in mortality has been attained is worthy of consideration by all who in any way care for patients with arteriosclerotic gangrene. The recommendations which have been made may be briefly stated as follows:

1. Careful individual consideration of each patient's problem rather than the too frequent perfunctory amputation in the hands of a surgeon not particularly interested or schooled in the factors involved.

2. A helpful cooperation between the medical and surgical staffs. Needless to say this is particularly important when diabetes is superimposed on the arteriosclerotic gangrene. With the diabetes under control the patient should not offer a greater operative risk than a nondiabetic patient. A careful evaluation of the cardiac and renal situation by the internist may be a life saving matter in determining just what procedure and anesthesia are safest.

3. Special surgical services and operative teams for amputation, which have definitely decreased the hospital mortality.³ While this arrangement has certain objec-

tions as applied to most institutions, there can be no doubt that it makes for better results.

4. Finally, the type of amputation which is carried out at the operative procedure.

It is the last phase, the treatment of the amputation stump, which is the principal concern of the present study. Does the particular type of amputation bear any relation to the morbidity or mortality? It is the writer's opinion and the opinion of others⁴ that it does. It is also our conviction that much more thought should be given to securing a live patient as an end result than a perfect weight bearing stump, a stump which all too frequently is never used.

More specifically the problem resolves itself into whether the usual anatomic fascial plane closure of the amputation stump is justified in cases of arteriosclerotic gangrene.

GENERAL CONSIDERATIONS

The problem of amputation of extremities having vascular damage sufficient to cause spontaneous gangrene is quite different from that presented by amputation for trauma. In the latter practically any of the many advocated types of plastic anatomic amputation may be carried out, because the blood supply to the area of operation is normal. The reverse is true in arteriosclerotic gangrene. Here the vascular bed has been diminished to the point where it will no longer sustain normal metabolism in the distal portion of the extremity. The effect of this on wound healing is evident. If a more or less complicated repair is carried out on the stump of such an extremity, the effective blood supply is still further diminished. The result too often is necrosis and suppuration of an otherwise beautiful anatomic repair.

Probably the most frequent type of operation used in arteriosclerotic amputation, whether in the thigh or the leg, is that which will be designated as the "fascial layer closure" type. Here the muscles and fascia are carefully sutured in one or more layers over the cut end of the tibia or femur. Skin flaps which have been fashioned and occasionally stripped from their underlying fascia are then carefully sutured in place over the fascial and muscular layers.

It is fully admitted that when such a repair heals by primary union the result is ideal and all that could be desired. However, in the case of arteriosclerotic gangrene this anatomic closure frequently becomes infected. The careful approximation of tissues with multiple constricting sutures has further devitalized tissues which at best have a poor blood supply.

It is of course highly desirable to obtain a good weight bearing stump at the first operation. This, however, is not justified if there is an appreciable added risk to the patient. It is the purpose of the present study to evaluate this risk and compare the results with those of simpler operative procedures in which the stump tissues are traumatized to a minimal degree.

Recently Crossan⁵ has advocated the simplest type of chop amputation. He has indicated the fallacies of dissecting skin flaps and muscle flaps at the expense of their own blood supply. McKittrick¹ and also Smith⁶ have expressed preference for a guillotine chop amputation, especially when there is any evidence of infection. The stump is left wide open so that maximal drainage is allowed and there is no interference with

the remaining blood supply from constricting sutures. Of course a secondary operation is usually necessary after such a procedure. Frequently, however, this consists only of amputation of the bone at a higher level.

Another type of simple closure consists of merely closing the skin with several loosely tied interrupted sutures. The tissues are thus only slightly constricted, and drainage can easily take place from the margins of the skin. Sometimes when there is considerable danger of infection these sutures can be placed at the time of operation. Later, when the progress of the wound can be more accurately estimated, they can be tied. A wound handled in this manner seldom has to have a secondary operation.

Adhesive traction applied to the skin above the stump is of definite aid in relaxing the tension of the tissues over the bone.

One further point in the general consideration of a gangrenous extremity is the part played by infection. Frequently the gangrenous area may appear perfectly benign, only to harbor bacteria in the neighboring fascial planes. This may cause an immediate flare-up after operation. Other extremities are grossly infected. In both of these instances the patient's chance of survival is certainly much better with the wound left wide open without tension.

A trial suture is sometimes used with the intention of reopening the stump if evidence of infection should develop postoperatively. There is of course no alternative for such a situation. However, it is generally admitted that this produces a problem which is far more serious than if the wound had been left open. Sepsis too often thus gains a foothold which a debilitated patient is unable to meet.

The importance of infection as a cause of death was emphasized by McKittrick and Pratt.⁶ They found that approximately one half of their postoperative deaths were directly or indirectly due to infection of the stump. This is in agreement with the figures for the series here reported.

MATERIAL

The cases studied represented consecutive admissions for arteriosclerotic gangrene of the lower extremity to the Indianapolis City Hospital and the Robert W. Long Hospital during the eight year period from 1930 to 1938. The greater part of these have been reported previously.² However, because of some rather interesting observations, the study has been continued so as to include the present larger number of cases. Cases in which major amputation was not performed have been excluded. Also excluded were those of amputation for vascular disease other than arteriosclerosis (atherosclerosis). Diagnoses were based on pathologic study of the amputated extremity.

No division of the cases was made as to amputation at the thigh or the leg. So far as the local stump healing is concerned, the same factors exist at the two sites. The blood supply to the thigh stump is of course better, but the same danger of infection and strangulation of tissue by anatomic repair is present at the two sites.

Cases of arteriosclerotic gangrene with diabetes and without diabetes are considered together with regard to stump healing. This is logical, since the local vascular and pathologic problem is the same. The diabetic patient has the added burden of diabetes, but so far as the local lesion is concerned this is important only when

the diabetes is out of control. The resultant mortalities for the diabetic and the nondiabetic patient have been considered separately.

This all inclusive grouping is of course open to just criticism. However, practically the same ratios obtain for the figures on wound healing when the series is broken down into subgroups. Therefore there seems nothing to be gained over the presentation of the total figures.

MORTALITY

In the entire series of cases of arteriosclerotic gangrene 137 major amputations were done in 117 cases. There were forty-four hospital deaths, giving an amputation mortality of 32 per cent and a case mortality of 37.6 per cent. As might be expected, the patients with diabetes or infection showed a definitely higher mortality than those without complications:

A. In the cases of diabetes and arteriosclerotic gangrene ninety amputations resulted in thirty-one deaths, a mortality of 34.4 per cent. These deaths occurred in seventy-eight cases, giving a case mortality of 39.7 per cent. The mortality was even higher when local or

TABLE 1.—Fascial Layer Closure of Stump Used in Ninety Amputations for Arteriosclerotic Gangrene With and Without Diabetes

	Cases	Per Cent
Deaths in the hospital.....	39	43.3
Deaths directly or indirectly due to infected non-healing stump	18	46.0

Of the fifty-one survivors, prompt healing oc- curred in	19	37.0
Expectancy of prompt healing (based on original ninety cases)	19	21.1

systemic infection was an added complication. Of forty patients having local cellulitis, lymphangitis, adenitis or leukocytosis, twenty-one died, a mortality of 52.5 per cent.

B. In the cases of arteriosclerotic gangrene without the complication of diabetes there were forty-seven major amputations, with thirteen deaths (27.7 per cent). These deaths occurred in thirty-nine cases, giving a case mortality of 33⅓ per cent. Infection of the operative stump was an important factor in only four of the deaths. The remaining nine patients died as a result of systemic vascular disease, embolism or pneumonia.

These alarming mortalities are certainly cause for speculation.

STUMP HEALING

When a surgeon prepares skin flaps and muscle flaps and carefully closes these in layers over the end of the bone, he does so with the conviction that he will obtain prompt healing in the majority of cases. He likewise expects to obtain a good weight bearing stump whether the amputation has been done in the leg or the thigh. These laudable aims form a startling contrast with the actual results obtained, or at least with the results obtained in the present series.

Table 1 shows that in ninety cases of arteriosclerotic gangrene in which fascial layer closure was carried out there were thirty-nine hospital deaths (a mortality of 43.3 per cent). Further, it is noted that nearly one half of these deaths (46 per cent) were directly or indirectly due to an infected, nonhealing stump. This in turn must be largely attributed to faulty care of the stump

6. McKittrick, L. S., and Pratt, T. C.: Principles of and Results After Amputation for Diabetic Gangrene, *Ann. Surg.* 100: 638 (Oct.) 1934.

in constricting the already devitalized tissues with numerous sutures and not allowing adequate drainage. Table 1 also shows that 63 per cent of the fifty-one patients who survived had suppuration and secondary healing of the stump. Prompt healing occurred in but nineteen (37 per cent) of these survivors. But, when one considers the entire group of ninety patients who received fascial layer closure, the percentage of stumps which healed promptly shrinks to 21.1. This figure represents the expectancy of prompt stump healing in those cases in which a fascial layer closure was performed.

With this outlook, 21.1 per cent of prompt healing and a mortality of 43.3 per cent, this type of closure is certainly questionable. It adds a definite risk which is not justifiable and should be reserved only for those patients who have an exceptionally good blood supply and no evidence of infection.

The question naturally arises, If the fascial layer type of stump closure is so hazardous, what have the other methods to offer?

Such a comparison of the operative procedures alone is of course invalid. Too many other factors enter into the problem. However, the differences in mortality are

No suture, secondary closure.....	51.5
Loose skin closure only.....	37.5

so great that they should be cited. In table 2 it will be seen that when a fascial layer type of closure was done the mortality was 43.3 per cent. This dropped to 19 per cent when there was no closure or secondary closure and to 16 per cent when a loose skin closure alone was done.

These figures gain in weight when it is realized that, in general, patients with the most favorable prognosis received fascial layer closure. Also the patients with a less favorable prognosis, for whom the operator felt that primary anatomic closure was unsafe, are included in the second and third subgroups. Regardless of this, the mortalities are sufficiently lower and indicate the added risk of fascial layer closure.

HOSPITALIZATION

It is with the hope of securing primary healing and early discharge from the hospital that the operator attempts an anatomic stump closure. Yet it may be this very attempt which devitalizes the tissues of the stump to the extent that necrosis and infection occur, adding to the hazard and prolonging the hospital stay.

In table 3 is shown a comparison of the average number of postoperative days in the hospital for three different operative procedures. It will be noted that the average hospital stay after anatomic closure is high, 49.5 days. This is in spite of the fact that this subgroup contains numerous patients whose stump wounds healed

promptly and who were discharged from the hospital between the fourteenth and twenty-first postoperative day.

From this it may be concluded that the average post-operative hospital stay was not reduced by fascial closure of the stump. On the contrary, it was increased by twelve days over the stay following simple skin closure.

It is of course desirable to obtain a good weight bearing stump. In the present series this seemed to be of secondary importance. Time and again the elderly patient was given an artificial limb only to discard it for crutches. This is in sharp contrast with the action of the younger patient who has had a traumatic amputation.

SUMMARY AND CONCLUSIONS

Arteriosclerotic gangrene with or without the complication of diabetes carries a heavy operative mortality.

In the present series, when major amputations were done the case mortality was 37.6 per cent and the amputation mortality 32 per cent.

While many factors enter into the problem, attention is called to the relation of operative procedure and stump healing to mortality.

The usual anatomic fascial plane closure in the majority of instances (a) devitalizes the already poorly nourished stump tissues, thus predisposing to necrosis and suppuration, (b) allows inadequate drainage for infected stumps or stumps which become infected, (c) results in only a small number of promptly healing stumps (21.3 per cent of those operated on in the present series), (d) definitely increases the operative risk and (e) does not shorten the average postoperative hospital stay.

Nearly one half of the hospital deaths are directly or indirectly attributable to necrosis and sepsis of the amputation stump.

In the great majority of amputations for arteriosclerotic gangrene no thought should be given to skin flaps or stump repair. The simple circular amputation is by far the safest. In general this consists of a circular incision of the skin at the operative site in the leg or thigh. The dissection is carried perpendicularly through the fascia and muscle layers at the level of skin retraction. No attempt is made to fashion skin flaps or separate the fascial planes, as these procedures tend to interrupt an already diminished blood supply. Gentle retraction on the muscles will allow bony resection at a somewhat higher level. When infection is a danger, no attempt is made to close the stump. This leaves it in a condition for maximal drainage. When infection is but a slight hazard, the skin may be closed with a few interrupted sutures. This allows drainage without constriction. When there is any doubt as to the possibility of sepsis, it may be well to place the skin sutures at the time of operation and, if the healing progresses satisfactorily, they may be tied a few days later. In the extremely septic patient, often with uncontrollable diabetes, the safest procedure would seem to be a simple chop amputation at or just above the knee, which minimizes the danger of opening or disturbing the muscle planes.

The anatomic fascial plane suture of the stump should be reserved for the exceptional case in which there is no infection and an abundant blood supply.

The surgeon must not lose sight of the fact that he is dealing with a very serious situation. The patient's life must receive prime consideration rather than the attempt to produce a perfect anatomic stump.

MAJOR AMPUTATIONS FOR ADVANCED
PERIPHERAL ARTERIAL OBLITER-
ATIVE DISEASE

HENRY H. FAXON, M.D.
BOSTON

In the Peripheral Vascular Clinic of the Massachusetts General Hospital in the ten year period from Jan. 1, 1929, to Jan. 1, 1939, there have been 530 patients with sufficiently advanced arterial obliterative disease to require admission to the hospital. Of that number 204 have had single major amputations and fifty-eight have had bilateral amputations. My paper is based on this material.

GENERAL CONSIDERATIONS

The treatment of this trying condition should be concerned primarily with those measures which, with reasonable safety to the patient, hold out the greatest hope of painless independence consistent with the known prognosis of the disease and the age of the patient. It must be remembered that the peripheral lesion is but one manifestation of a generalized progressive process and that a protracted hospital stay to save a potentially useless extremity is neither a kindness to the patient nor an intelligent utilization of the beds of a charitable institution.

For an intelligent application of these criteria of treatment in the care of peripheral arterial disease, the cases must be subdivided into the three clinical entities of Buerger's disease, or thrombo-angiitis obliterans, peripheral arteriosclerosis and peripheral arteriosclerosis associated with diabetes mellitus. Each of these subdivisions has definite surgical characteristics and economic implications that justify a wide difference in procedure; the lesions are apparently similar, but the underlying pathologic process is different.

Progressive arterial disease did not precipitate a single major amputation of the upper extremity in the ten year period studied, although in many instances the vessels of the arm showed clinical evidence of advanced involvement in the same pathologic process that was the basis of the signs and symptoms in the leg.

Conservative Treatment.—Any method of treatment, such as sensory nerve block, incision and drainage, minor amputation or lumbar sympathectomy, that obviates the necessity of major amputation and yet rehabilitates the patient is always carried out if warranted by the status of the peripheral circulation. In a study of the same series of cases, McKittrick¹ has reported in detail the experience which my associates and I have had with the use of these conservative measures, but it might well be stressed here that the technical simplicity of an operation is by no means a true measure of its degree of conservatism, for an ill advised toe amputation or poorly conceived incision and drainage of an infected area may be the most radical procedure to which the patient could be subjected.

Diagnosis.—An appreciation of the presence of an impaired peripheral arterial circulation and a practical determination of its extent do not require the use of any instruments of precision, for simple palpation and

observation readily reveal absence of or diminution in the intensity of the pulsations of the peripheral arteries as well as coolness and a color change of the skin not found in the normal extremity. Furthermore, the consistency with which the story of intermittent claudication, subjective coldness of the feet and persistent apparently trivial lesions of the toes is repeated should lead any surgeon to consider seriously the possibility of progressive arterial occlusion.

The results of urinalyses and the blood sugar levels determine whether or not diabetes mellitus is present as an associated complicating factor with arteriosclerosis.

As our criteria for establishing the differential diagnosis between arteriosclerosis and Buerger's disease have been reported in detail by Allen² and McKittrick,³ it is sufficient to state here that the following constitute the salient differences between these conditions (table 1):

1. The incidence of Buerger's disease is less than one third of that for arteriosclerosis with and without diabetes.

Double amputation	12	11	15	8	31	13

* No amputation, 50 per cent; single amputation, 39 per cent, and double amputation, 11 per cent.

2. Buerger's disease is confined to males and involves younger patients than does arteriosclerosis.

3. The duration of symptoms prior to admission to the hospital is longer in Buerger's disease than in arteriosclerosis.

4. The five year life expectancy following successful major amputation is four times greater for patients with Buerger's disease than for those with arteriosclerosis.

5. An open lesion associated with Buerger's disease is invariably extremely painful, whereas pain is a far less striking factor in similar lesions with an arterio-sclerotic basis, especially if associated with diabetes mellitus.

MAJOR AMPUTATION

Incidence.—As one would expect in the light of the fundamental differences already referred to, major amputations are necessary in far fewer cases of Buerger's disease than of arteriosclerosis (table 2). However, the proportion of patients coming to amputation

From the Peripheral Vascular Clinic of the Massachusetts General Hospital.

Read before the Section on Surgery, General and Abdominal, at the Ninetieth Annual Session of the American Medical Association, St. Louis, May 18, 1939.

Mrs. Eunice Wilson and Miss Katherine Foster of the House Social Service Department assisted in securing follow-up data on the resulting function in these cases.

who require bilateral procedures is strikingly higher for Buerger's disease than for arteriosclerosis.

For the arteriosclerotic patients without diabetes the incidence of amputation was relatively high, but the proportion of patients with both extremities subjected to amputation was low as compared with the patients in whom diabetes mellitus was an associated condition. This is explained in part by the fact that among diabetic patients there are many with a favorable prognosis whose problem is primarily one of sepsis in a foot with

good circulation, whereas in arteriosclerotic patients the circulation is almost invariably poor. When diabetes and advanced arteriosclerosis coexist, the presence of the diabetes increases the probability that the remaining extremity will have to be sacrificed.

The average interval between operations on the two sides in bilateral amputations was forty-three months for the patients with thrombo-angiitis obliterans, twenty months for the arteriosclerotic patients and twenty-five months for the diabetic patients.

The most important single factor in the lowering of the incidence of major amputations for patients with Buerger's disease during the period studied was the introduction into our clinic of sensory nerve block by Smithwick and White.⁴ This procedure is most suitable for patients with thrombo-angiitis obliterans who present open painful lesions, and by employing it for 27 per cent of such patients we have reduced our incidence of major amputations from 74 to 31 per cent for patients with thrombo-angiitis obliterans.

Types.—It is all important at the onset of this discussion to point out the clearcut distinction between a guillotine, or preliminary open operation, and a closed undrained type of amputation. The former was carried out as a simple circular procedure in fifty-two instances in which we felt that the life of the patient was seriously jeopardized by the presence of infection in the extremity. In all save three of these the site of operation was through the lower part of the leg, and no attempt was made to modify in any way the simplest possible procedure lest the very purpose of ridding the patient of his infection be defeated by a further spread of the sepsis.

The midportion just distal to the main bulk of the gastrocnemius muscle was selected as the site of choice for this procedure, but when the streaks of lymphangitis extended above this level the open amputation was usually done in the upper third of the lower part of the leg. It is desirable to carry out the operation above the level of demonstrable lymphatic involvement, but if a pulsation is present in the popliteal artery of a relatively active person this consideration may be disregarded in

order to leave enough of the lower part of the leg to permit the carrying out of a Gritti-Stokes amputation as a secondary procedure.

Vertical 1 inch incisions through the fascia were carried up from the site of operation to prevent any tendency toward limitation of the drainage by stenosis of cicatricial tissue at the end of the stump. The application of a ham splint and some form of ointment dressing has been found to give the patient the maximum amount of comfort after this type of procedure, although in certain instances the use of diluted solution of sodium hypochlorite has been deemed advisable.

A secondary closed amputation at a higher level was always contemplated and was carried out in 84 per cent of our patients who survived the guillotine procedure. We now feel that this secondary operation can usually be carried out approximately three weeks after the initial operation. We feel that the type of preliminary open amputation advocated here assures the extremely ill patient of the best chance of surviving but, even with subsequent plastic operations, does not result in a satisfactory stump.

The success or failure of a guillotine amputation in combating infection as a rule is evident from the clinical chart within forty-eight hours by a return of the elevated temperature to an essentially persistent normal level, as shown in the accompanying chart. In those cases in which hemolytic streptococci persist in the granulations of the open amputation, an initial course of sulfanilamide therapy is employed to rid the wound of these organisms and the drug is given three days before and after the secondary operation to protect the patient against reactivation of the infection.

An open amputation was done as a preliminary procedure in 10 per cent of the entire series of cases, the incidence of the procedure being approximately one half as great for the patients with Buerger's disease as for those with arteriosclerosis (table 3).

A closed amputation was carried out as a primary procedure in 40 per cent of the total number of cases.

It is our belief that with meticulous hemostasis in the types of amputation we advocate, drains serve only as a source of irritation and potential infection, and in only five instances were the wounds drained; this is in con-

trast to the use of drains in 72 per cent of the major amputations done from 1916 to 1926 at this hospital and reported by Wilson.⁵ The hospital mortality in the cases of progressive obliterative disease in the earlier period was 24 per cent, and we feel from a study of the figures that the avoidance of drains in the present series ranks close to the advent of insulin as a factor in reducing our present mortality to 13.1 per cent.

We fully realize the functional advantages of preserving the knee joint, but it has been our experience that when the underlying pathologic process is of a progres-

sive nature, amputation at the lower part of the leg does not prove permanently successful. Even with thrombo-angiitis obliterans accompanied by a palpable pulsation of the popliteal artery, for which the prognosis is the most favorable, a second amputation at a higher level was eventually necessary in 75 per cent of the cases in which our enthusiasm to save the joint led us to carry out as the original procedure an operation on the lower part of the leg.

In no instance in which an amputation at or above the knee was carried out was it necessary to reamputate because of circulatory difficulty in the end of the stump.

It is our feeling that the Gritti-Stokes type of operation provides the most suitable weight bearing stump for patients whose general condition and underlying pathologic process render the prognosis favorable for a future of economic usefulness.

Since the outlook for continued years of activity is so much greater for patients with thrombo-angiitis obliterans than for arteriosclerotic patients, it is not surprising that the incidence of Gritti-Stokes amputations in the former group (62 per cent) was more than twice that for the older patients (21 to 32 per cent), as shown in table 4. Another factor in our preference for this type of procedure for patients with Buerger's disease and our apparent reluctance to adopt it for arteriosclerotic patients is the fact that the former patients will tolerate a complicated technical procedure infinitely better than the latter. That the Gritti-Stokes operation lays a greater demand on the general resistance and local process of repair is suggested by the fact that 68 per cent of the total number of patients submitted to this type of amputation have shown either a postoperative rise of at least 2 degrees Fahrenheit or an increase in the pulse rate of more than thirty points, whereas only 44 per cent of those submitted to a thigh amputation have done so. This observation has not been colored by either the length of operation or the choice of anesthetic, for the duration of each type of procedure has averaged almost exactly one hour, and spinal anesthesia has been used for 91 per cent of all our major amputations regardless of operative technic.

The absence of a popliteal pulsation does not per se contraindicate the use of the Gritti-Stokes type of amputation, for the potentially rich collateral circulation about the knee joint frequently more than compensates for occlusion of the main vessel. In twelve instances in which this operation was carried out, it was specifically noted that no pulsation could be made out in the popliteal artery, but under this circumstance this procedure should never be carried out if color changes in the skin denoting a precarious collateral circulation are noted at or above the ankle when the foot is in the dependent position.

A thigh amputation done with a simple circular incision and division of the fascia and bone at progressively higher levels to permit closure of the layers without drainage is the safest closed major amputation of an extremity to which the patient can be subjected. For this reason it should be the procedure of choice for patients whose general condition is so poor that there is little hope of their using a prosthesis and for whom the chief aim of operation is removal of the distal portion of an extremity which is hopelessly involved in infection or gangrene. This situation was more frequently seen with arteriosclerosis, and consequently the incidence of thigh amputations for this condition was more than two and one-half times that for thrombo-angiitis obliterans, with its more favorable prognosis.

We have found that this procedure is attended with less postoperative reaction than any of the other types of major amputation we have employed, and we have had only one instance of shock following it.

The lower portion of the thigh, just above the patella, is a more desirable site for such an amputation than the more bulky level of the upper or middle part of the thigh, and in only two instances have we been forced by potential infection and inordinately poor blood supply to operate at the higher site.

Although in many of the more recent thigh amputations we have done a tendoplastic type of operation, we never employ long skin flaps such as those advocated by Callendar,⁶ as we believe that in extremities such as those under consideration the circulation in these flaps is apt to be too precarious to insure primary healing.

Indications for Preliminary Open Major Amputations.—We recognize the following as the indications for carrying out a guillotine type of operation through the lower part of the leg:

1. Progressive ascending infection with signs of extending lymphangitis at or above the ankle.

Clinical course in a case of nondiabetic arteriosclerosis with persisting infection of the foot and extending lymphangitis of the lower part of the leg.

2. General manifestations of persisting, overwhelming infection arising from a septic extremity, with an elevation of temperature over 103 F.

An appreciation of the fundamental differences between the behavior of the three types of progressive arterial disease under discussion is of vital importance in determining how long a period of observation and conservative treatment is justifiable. In Buerger's disease an infectious process tends to remain confined to the foot, whereas in arteriosclerosis, especially when diabetes mellitus is present as an associated factor, a rapid, extensive spread by way of the lymphatics and blood stream is not uncommon.

That the presence of diabetes, even though under control, provides a very real added hazard cannot be overstressed, and it is especially important with this condition that no undue optimism be allowed to influence a rigid adherence to the indications for operation already noted. The diabetic patient with spreading infection or overwhelming sepsis represents both a medical and a surgical emergency, and delay in the

6. Callendar, C. L.: Tendoplastic Amputation Through the Femur at the Knee, J. A. M. A. 110: 113-118 (Jan. 14) 1938.

adoption of surgical intervention as the method of treatment is rarely justifiable, whereas a period of twelve hours of observation may be adopted for patients with arteriosclerosis unassociated with diabetes, and an interval of twenty-four hours may be utilized with equal safety for patients with thrombo-angiitis obliterans.

Naturally no arbitrary stipulations can be formulated to cover all conditions, and the surgeon should consider it his responsibility to keep in such close contact with this type of case that he will be ready to operate without delay at any time when the infection gives evidence of

extending despite conservative measures. If improvement of the septic process is noted at successive periods of observation, conservative treatment may be continued until the lesion has regressed to the quiescent state in which the criteria for primary closed amputations apply.

Indications for Primary Closed Amputations.—We have come to believe that in a case of peripheral arterial disease the following represent the indications for primary closed major amputations:

1. Infection or gangrene in a pulseless foot involving all of one or more toes.
2. Infection or gangrene proximal to the base of the digits in a foot with palpable arteries that under conservative treatment continues to extend.
3. The involvement by infection or gangrene of so much tissue that any so-called successful treatment will consume a major part of an individual's life expectancy or result in a functionally useless extremity.
4. The persistence of pain either in the presence or in the absence of an open lesion which cannot be controlled within a three weeks period of hospital care and adequate conservative treatment.
5. A history of repeated incapacitating ulcerations of an extremity on which all conservative measures compatible with the status of the circulation have been carried out.

These indications must be interpreted according to the underlying pathologic process because of the marked difference in economic potentialities and resistance to infection that exists between patients with thrombo-angiitis obliterans and those with arteriosclerosis. It is especially true of the former patients that an exception may be made to these stipulations if an adequate collateral circulation can be demonstrated by the persistence of a normal color of the skin of the extremity on elevation and dependence.

As patients for whom major amputation is contemplated are in no such precarious condition as those facing preliminary open amputation, a longer interval of study may be safely employed to evaluate their condition. Undue procrastination, however, is indefensible,

especially when diabetes is present, and there can be no more glaring example of mismanagement than to be forced to do a guillotine operation on a patient who, at an earlier period of his hospital observation, presented clearcut indications for a closed procedure.

The fundamental differences between Buerger's disease and arteriosclerosis should be weighed in determining the level of amputation, and the arterial blood supply of the selected site should be sufficient not only to insure primary healing but also to maintain the end of the stump in normal condition under its anticipated demands.

In 12 per cent of the patients, sepsis of sufficient extent to prolong the hospital stay developed. Twenty-five patients with infection had undrained closed amputations, but of these only one died because of this complication. Seven patients on whom a preliminary open operation had been done showed extension of their sepsis at the site of the guillotine amputation, and of these two died as a result of this condition.

In only four of our earlier cases did we have to deal with a *Bacillus welchii* contamination despite the fact that we do not as a routine employ the prophylactic use of gas bacillus antitoxin. The patients who showed sepsis in their stump probably represented an error as much in the proper selection in the type and site of amputation as in the actual operative technic.

Mortality.—An important factor in any operative mortality is the degree to which the performance of the operation and the care of the patient are delegated to a limited number of persons. Although six surgeons of the visiting staff have maintained a continuous active interest in the clinic since its inception, a large number of the amputations have been carried out by the more recent additions to our group and by the frequently changing personnel of the house staff.

In determining the hospital mortality in this series of cases, with two exceptions, we attributed any death which occurred during the stay at the hospital in which the major amputation was done to the operation. One

TABLE 6.—Causes of Hospital Deaths, Thirty-Six Cases

of the deaths excepted followed a laparotomy for carcinoma of the stomach and the second a hysterectomy carried out for a twisted pedunculated fibroid growth.

The hospital mortality for the 262 major amputations in this series was 13.1 per cent (table 5).

For the patients on whom it was necessary to do a preliminary open amputation the mortality would presumably have been staggeringly high without operative intervention, and we feel that with such extremely ill patients our hospital mortality of 25 per cent justifies our enthusiasm for the use of a guillotine procedure through the lower part of the leg.

The relative operative risk in the three subdivisions of the series is well illustrated by the fact that with preliminary open operations there were no deaths of patients with Buerger's disease, a 25 per cent mortality for the arteriosclerotic patients and a 32 per cent mortality for the diabetic group. It is interesting to note that only one of the patients who had a closed amputation secondary to a guillotine procedure died, and his death was not due to sepsis.

For the primary closed amputations the mortality was 9.6 per cent, with a figure of 4 per cent for the patients with Buerger's disease and 11 per cent for the arteriosclerotic groups.

Pulmonary complications, the majority of which were bronchopneumonia, accounted for the greatest number of deaths, with cardiac complications and infection next and of almost equal importance (table 6). In four of the six cases in which death was due to infection, it was the sepsis of the stump that was primarily responsible. Four patients died of emboli.

Function.—The ability of the patient to employ a prosthesis successfully does not depend solely on the level and condition of the amputation stump. His general mental and physical vigor, the care with which he is instructed in the use of his pylon and the condition of his remaining extremity are more important factors in his rehabilitation than the type of procedure that has been carried out.

It has been our practice to equip our patients with temporary limbs and give them at least a few days instruction in the use of these before they leave the hospital. Temporary limbs which are simple in construction and appearance are employed for the period of shrinkage of the stump and in many instances these are used indefinitely as a matter of choice by the patient. With a Gritti-Stokes or thigh amputation, a patient who cannot handle the rigid, full length type of appliance should be spared the mental and financial disappointment of being "graduated" to one of the knee action type of limbs.

Eighty-eight per cent of the patients with Buerger's disease who had a single amputation mastered the use of a prosthesis, as compared with approximately 50 per cent of the more elderly arteriosclerotic patients (table 7). Naturally there is a wide variation in the proficiency attained in the use of the pylons.

Every patient with thrombo-angiitis obliterans who had a single amputation secured some type of pylon, while almost exactly one fourth of both the arteriosclerotic and the diabetic patients who had a single amputation did not obtain any appliance for, with these segregated groups, the likelihood that a prosthesis would be used did not seem to warrant the financial outlay involved.

When bilateral amputations were carried out, two thirds of the patients with Buerger's disease used some form of artificial appliance. It is discouraging to find that with bilateral amputations it was deemed feasible to provide pylons for only one third of the arteriosclerotic and one half of the diabetic patients.

CONCLUSIONS

1. A guillotine amputation through the lower part of the leg for critically ill patients with ascending infection is indicated as a life-saving measure.

2. The open operation does not result in a satisfactory stump in cases of obliterative arterial disease and should be considered as a preliminary step to a secondary closed amputation at or above the knee.

3. A closed amputation through the lower part of the leg rarely proves permanently satisfactory in cases of advanced arterial obliterative disease.

4. The Gritti-Stokes amputation is the most satisfactory procedure for a patient with arterial disease whose general condition does not preclude the use of a prosthesis.

5. A simple low thigh operation is the safest major amputation of an extremity that can be carried out and is the procedure of choice for enfeebled patients for whom a major amputation is indicated.

6. Drains should never be used in primary closed amputations.

7. The decision as to the advisability and site of amputation should include due consideration of the nature of the underlying pathologic process, the future usefulness and life expectancy of the patient and the status of the peripheral circulation.

264 Beacon Street.

ABSTRACT OF DISCUSSION

ON PAPERS OF DRS. TAYLOR AND FAXON

DR. LELAND S. MCKITTRICK, Boston: Our problem was not quite what Dr. Taylor faced, because one of our seniors, the late Dr. D. F. Jones, had gone a long way toward teaching us the fundamental principles in the management of this group of cases. May I stress one of the points that he has made, and that is the importance of cooperation between the surgeon and the physician; not only must there be cooperation, but if the surgeon is not interested in vascular disease, if he does not want to give the detailed attention necessary to the diabetic patient with gangrene, he ought not to take the responsibility. Therefore the cooperation must be between interested people. With regard to where and how to amputate, it seems to me that there are two or three decisions that we must make. We must decide in our own minds (1) what is the safest amputation I can do in the presence of extending infection, (2) what is the safest closed amputation I can do and (3) what is the best amputation for this particular patient. As Dr. Taylor said, if one is facing probable fatality, one had better not worry what is the best amputation but rather try to save the patient's life. I believe that the safest amputation to do in the presence of fulminating, overwhelming infection is a guillotine amputation, in most instances done below the knee. I nearly always do a reamputation at a higher level when the condition of the stump and the condition of the patient permit. There seems to be no definite agreement as to the safest closed amputation. Callander feels that it is his modification of the Gritti-Stokes procedure. Smith of New York will say that it is his operation below the knee. For me and for the members of the Peripheral Vascular Clinic at the Massachusetts General Hospital the safest closed operation is a supracondylar amputation. Operation should be done without a tourniquet. A circular incision is used. Nothing which touches the skin is allowed to touch the inside of the wound, and the wound is closed without drainage. We have obtained primary wound healing in 93 per cent of our cases, and in only 2 per cent of 100 consecutive cases was stump sepsis a factor in death. I should like to point out that in the group reported by Dr. Faxon a very high percentage of the amputations were done by our surgical resident staff—men of immature experience, just beginning to learn their surgical technic—but they had been told when to operate and where to amputate. In other words, if one can make up one's mind early to do an amputation when it is indicated, whether to do an open amputation below the knee or a closed amputation above the knee, I believe that the results will be just as good as Dr. Faxon's or Dr. McKittrick's.

DR. GEZA DE TAKATS, Chicago: I should like to state briefly my experience with the Callander type of amputation. This type of amputation does not cut through muscles but cuts through tendon insertions; adequate drainage can be procured for four or five days. In thirty-five amputations our mortality has been 11 per cent. In a comparative group of sixty-five

patients on whom lower thigh amputations have been performed the mortality was 27 per cent. This series, of course, is very small. One is, however, impressed with the fact that, while one can maintain free drainage for four or five days, the clips are then applied and an excellent weight bearing stump can be obtained without reamputation. We have had unfortunate experiences with gas gangrene following amputations, even in patients receiving from two to four prophylactic doses of antitoxin, and I should like to ask both Dr. Faxon and Dr. Taylor whether or not they have had any gas gangrene in their series. As to the level of the amputation, I believe that in addition to the palpation of pulses and the sudden drop in skin temperature the study of cutaneous histamine flares is a very exact guide to the level at which a skin flap will take.

DR. HENRY H. FAXON, Boston: As regards the question of gas bacillus infection, it is of interest to note that the four cases presenting this complication were all early in our series, the last one occurring in 1931. I do not employ gas bacillus antitoxin as a routine measure for I feel that skin contamination is the primary source of such infection and that with proper preparation of the extremity for operation this complication should not occur. In recent years I have laid special emphasis on the fact that the involved distal portion of the extremity should be completely isolated by a separate dressing from the site of amputation. The preoperative preparation should not encroach on the area of apparently normal skin adjacent to the infection, and only the gentlest cleansing of the skin at the site of operation is permitted. I feel that these steps have played a major part in reducing the incidence of gas bacillus infection and that no preoperative preparation of the extremity is far more desirable than one that carries with it the risk of transmitting *Bacillus welchii* into the operative field.

THE VALUE OF EARLY OPERATION IN CHRONIC PRIMARY GLAUCOMA

ALGERNON B. REESE, M.D.

NEW YORK

There seems to be a considerable difference of opinion among ophthalmologists regarding the tractability of chronic primary glaucoma to operative treatment. There are those who believe that the disease can be arrested in most cases by well chosen and well executed operation when indicated, and there are others who take a much less optimistic view.

Judgment in the choice of the operation and the technique employed do not seem to be the most important factors in this difference of opinion; it rests rather on the time in the course of the disease at which the operation is performed. My own observations have inclined me to the opinion of those ophthalmologists who hold that primary glaucoma is relatively tractable if the patient is operated on in the early stages of the disease when an operation is indicated and relatively intractable if the operation is deferred until the disease has advanced.

In an effort to establish this belief on a more certain footing, I have studied a series of 105 selected cases (153 eyes) of chronic primary glaucoma¹ in which a trephine operation was performed. The fields of vision and blind spots, together with tonometric readings, were recorded before the operation and again repeatedly after the operation for an average follow-up period of over four years. In many instances observations made

on gonioscopic examinations were available. All cases in the following categories were excluded from the series:

1. Primary glaucoma in Negroes, because the disease is notoriously intractable in this race.
2. Primary glaucoma in eyes later subjected to cataract extractions, which complicated postoperative follow-up studies.
3. Cases not followed over a sufficient period of time after operation.
4. Cases presenting incomplete perimetric and tonometric determinations before or after the operation.
5. Incipient or chronic cases which were made acute by the use of mydriatics.
6. Cases in which any question of secondary glaucoma has arisen.
7. Cases in which there was any question of defective operative technic and in which any postoperative complication seemed to influence the result.

These 105 cases of chronic primary glaucoma, selected in accordance with the foregoing stipulations, were divided arbitrarily into so-called early and so-called advanced cases.

The early cases were considered to be those in which the peripheral fields had not contracted to a point closer than 30 degrees of fixation in any meridian and in which the blind spots were not larger than 15 degrees in any diameter. It follows that the advanced cases comprised those in which the peripheral fields had contracted in any meridian to closer than 30 degrees of fixation and in which the blind spots were enlarged more than 15 degrees.

The presence or absence of a cupping of the optic disk could not be used satisfactorily as a criterion in classifying these cases. It can only be said that the majority of the so-called advanced cases presented cupping. Cupping was rare in the early cases and when present seemed to be an unfavorable sign.

The early cases examined with the gonioscope showed mostly open filtration angles, while the late cases showed the angles closed, either in part or entirely, by peripheral synechiae. Many of the eyes were not examined with the gonioscope.

EARLY CASES

There were fifty-one eyes classified as early glaucoma at the time of operation. Of these, forty-six, or more than 90 per cent, showed arrested disease after an average follow-up of approximately five years from operation. The intra-ocular tension taken on many occasions during this period was always normal except in six instances, in which once or several times it was found to be as high as from 30 to 35 mm. of mercury with the Schiötz tonometer. The peripheral fields showed no further contraction, and in only eight cases was there any progressive enlargement of the blind spots (to an average of only 6 degrees). In only two cases was more than one operation performed; one of these showed a progressive contraction of the fields and will be discussed later; the other showed no progression and the tension was reduced to normal for the remainder of the follow-up period after the second operation.

The five cases in which operation failed to check progressive contraction of the peripheral fields or to control the intra-ocular tension will be taken up briefly:

1. Two operations were performed in this case and the intra-ocular pressure following each ranged from 30 to 45 mm. of mercury with the Schiötz tonometer. There were indications for still another operation, as the pressure was not controlled. The fields showed progressive contraction, and central vision was lost. Before the second operation the fields showed a nasal step and a 10 degree enlargement of the blind spot,

From the Eye Institute.

Read before the Section on Ophthalmology at the Ninetieth Annual Session of the American Medical Association, St. Louis, May 17, 1939.

1. These include both chronic noncongestive or simple glaucoma and congestive glaucoma, as I believe that in the present state of our knowledge we must consider them the same disease, producing congestive manifestations or not, according to the degree of the tension and the duration of time required for the vascular system of the eye to adjust itself to the increased tension.

which would probably put this case in the advanced group at the time the second operation was done. The gonioscopic examination revealed that ciliary processes were caught in the trephine opening, a factor which probably had an unfavorable influence on the drainage. The possibility that this was a case of secondary glaucoma must be considered: the slit lamp showed some synechiae and some nebulous folds in Descemet's membrane but no deposits on the cornea and no cells in the aqueous.

2. In this case another operation should have been performed, as the tension was obviously not controlled by the first one. It ranged from 25 to 33 mm. of mercury. The nerve head showed a definite cupping.

3. This case might also have been arrested had another operation been done, because the tension ranged from normal to 33. There was a deep cupping of the optic nerve.

4. This was a case on the borderline between early and advanced, as the fields before operation were 30 degrees from fixation in one meridian. The tension was not satisfactorily controlled, as it ranged from normal to 35. Another operation could possibly have prevented progression.

5. The tension in this case was also not controlled; it ranged from normal to 35.

ADVANCED CASES

There were 102 eyes classified as late cases. Of these, sixty-five showed progressive contraction of the visual fields following operation. Three showed improvement, followed later by contraction, and in nine cases the fields were so telescopic that it was difficult to determine the question of progressive contraction; it could only be surmised on the ground that central vision was lost.² Of the 102 eyes there were twelve in which the fields of vision had contracted beyond fixation, with loss of central vision before operation, so that it was difficult to determine the question of progression after operation. Of the remaining ninety eyes, sixty-five, or 72 per cent, showed progressive contraction of the fields following operation during an average follow-up period of over five years. Of these sixty-five eyes in which the fields progressively contracted, thirty-nine, or 60 per cent, had normal intra-ocular tension at numerous times over the average follow-up period and at no time was the intra-ocular pressure found to be above normal.

COMMENT

The operation done in the early cases successfully reduced the intra-ocular pressure to normal, where it remained during the four years and two months average follow-up period in more than 90 per cent of the cases. This percentage is not surprising when certain facts about primary glaucoma are considered. In the early stages there are no peripheral synechiae; but if the glaucomatous state is not relieved and exists long enough peripheral synechiae develop, increase in extent, ultimately occupy the entire circumference of the filtration angle and also increase progressively in breadth. It can therefore be said that peripheral synechiae do not cause glaucoma but that glaucoma causes anterior peripheral synechiae which in turn cause glaucoma. Here is a vicious circle which is initiated by the unknown factor in glaucoma. If a filtering operation is done while the filtration angle is still open, then the filtration load, which must be borne by the operation, is less than when the angle is closed over a portion or over its entire circumference.

2. Twenty-five eyes among the advanced cases showed progressive constriction of the visual fields to the point of so-called telescopic fields and then showed no further progression over the follow-up period. This central field remained in twelve instances in spite of the fact that the intra-ocular pressure remained above normal. In ten of the twenty-five eyes the patients retained central vision and five of these even showed an increased intra-ocular pressure over the follow-up period. The explanation for this seems to be that in some eyes the macular region receives sufficient nutrition from the underlying choroid to enable it to function independently of the retinal blood supply altered by the glaucoma.

Furthermore, if the filtration furnished by the operation is adequate to keep the intra-ocular pressure within normal limits, no further blocking of the angle by synechiae will occur and therefore, as time goes on, no additional burden will be placed on the filtration produced by the operation. This is true because an increase in the intra-ocular pressure per se produces peripheral synechiae. Witness the almost uniform presence of peripheral synechiae in the later stages of all types of glaucoma and the relation between the extent of the synechiae and the stage of advancement of the disease. Peripheral synechiae develop ultimately not only in primary glaucoma but in secondary glaucoma due to whatever cause. It is my belief that even in glaucoma of the deep chamber type peripheral synechiae develop if the intra-ocular pressure is elevated over a sufficiently protracted period. It seems, therefore, that an increase in the intra-ocular pressure per se, from whatever cause, produces anterior synechiae, and it follows that an early lowering of the intra-ocular pressure to normal prevents their occurrence and in so doing prevents an additional drainage load on the operation.

Of the late cases there were thirty-nine eyes out of sixty-five, or 60 per cent, which showed progressive contraction of the visual fields in spite of the fact that the intra-ocular pressure had been reduced to normal over the five year follow-up period following the operation. This would indicate that if the vascular changes occasioned in the retinal vessels by the increased intra-ocular pressure producing the peripheral field contraction have reached a certain degree or have gathered a certain momentum, so to speak, they continue to progress, thus producing progressive field defects in spite of normal intra-ocular pressure. This fact is also a strong argument in favor of operating early in cases of primary glaucoma, before this vascular process gathers sufficient momentum to progress regardless of the successful reduction of the intra-ocular pressure.

The results of this analysis show that chronic primary glaucoma is quite a tractable disease if the operation when indicated is done in the early stages. This is not possible in some instances because the patients do not present themselves for treatment until the disease has already made inroads, a tendency rising from the fact that the disease frequently has an insidious course with few symptoms. The ophthalmologist is familiar with even intelligent patients who, without realizing it, have practically lost the vision in one eye from glaucoma. General practitioners and the lay public should therefore be familiar with the cardinal symptoms of glaucoma so that patients may present themselves for diagnosis early enough to arrest the disease. The same importance should attach to the early recognition of and the early operation when indicated for glaucoma as is generally conceded for cancer. By the same token the ophthalmologist should be able to detect glaucoma in its earliest stages and even in its prodromal stage in many instances. This can be done only by the frequent use of the tonometer and by constantly suspecting glaucoma, particularly in predisposed eyes such as those with hyperopia and with shallow anterior chambers. If the diagnosis is not made until there is cupping of the optic disk, usually the disease has advanced too far to be arrested.

As soon as it has been established that the intra-ocular pressure in a case of primary glaucoma cannot be controlled by miotics, an operation is indicated.³ An

3. De Wecker said "If miotics have never cured a case of glaucoma, they have prevented many glaucomatous patients from being cured."

exception to this is the patient whose intra-ocular tension is somewhat above normal, even with the strongest miotics that can be used as a routine, but who has an expectancy, whether because of age or of poor health, which makes it justifiable to temporize with the idea that the vision will probably outlast the patient. An operation is also indicated when, with the use of miotics, the intra-ocular pressure is normal or near normal when it is measured but the visual fields continue to contract, the blind spots to enlarge and peripheral synechiae to form, all evidence that the tension is appreciably elevated at times when the patient is not under observation.

When the indications point toward an operation, no time should be lost in advising and even insisting on it. Quite frequently the patient, the physician, or both, tend to procrastinate. This is not surprising when we consider the fact that we are dealing frequently with a highstrung, nervous, apprehensive individual to whom we advise an operation on an eye usually with normal vision and often giving no symptoms. We promise this patient no tangible result as we do in squint and cataract cases. We can only state that we hope to save the vision for the future.

Too frequently the operation is deferred until the disease has advanced to the point at which the chances of arresting the process are slight. Then repeated operations are done in quick succession, all in vain, and glaucoma is branded a most intractable disease. For the best results the operation should be done before there is enlargement of the blind spots and constriction of the fields, and certainly before there is any cupping of the disk. When this desideratum is fulfilled, chronic primary glaucoma ceases to be one of the terrors of ophthalmology.

635 West 165th Street.

ABSTRACT OF DISCUSSION

DR. HARRY S. GRADLE, Chicago: The conclusions that Dr. Reese so ably presented should be spread broadcast not only to cure the intolerable pessimism of many of our colleagues regarding glaucoma but to urge those with glaucoma to seek attention early. The classification of the cases into the early and the late is most proper. There is no question that a late case of compensated glaucoma with the classic appearance of the cupped disk and the extensive field changes is a surgical case immediately; but there are many early cases that we are finding now, thanks to the better diagnostic methods, more commonly than we did in the past. I do not believe that Dr. Reese emphasized sufficiently the fact that early operation is desirable when it is indicated. It is true that, if the disease cannot be controlled by other than surgical methods, temporizing is to be avoided and early operation will produce the results that Dr. Reese has shown. But there must be definite indications for surgical intervention and we are not justified in operating in early cases of compensated glaucoma until we are sure that they cannot be controlled by nonsurgical treatment. We cannot be sure of the lack of control by nonsurgical treatment until a good many weeks or even a good many months have elapsed. We cannot be sure of lack of control if we depend entirely on the tonometric measure of intra-ocular pressure. We may obtain a given level of intra-ocular pressure that can be held by miotics, but whether that intra-ocular pressure is pathologically high for the eye in question can be determined only when the effects on the visual field and the central visual acuity have been determined. Those effects are slow in making their appearance and we must not judge too hastily. Therefore I am trying to stress the necessity of strenuous indications for surgery; but when surgery is indicated, then Dr. Reese is correct; nothing should be allowed to interfere with the immediate performance of such an operation.

INFECTIOUS RELAPSE IN SYPHILIS OF MORE THAN TWO YEARS' DURATION

HARRY PARISER, M.D.

PHILADELPHIA

The importance of infectious relapse in early syphilis has been discussed by many observers.¹ In the Cooperative Clinical Group studies² of 339 cases of mucocutaneous relapse, 84 per cent occurred within the first two years of infection and 91 per cent within two years after treatment had ceased. These figures correspond closely to those of Stokes, Besancon and Schoch,¹ who noted 93 per cent of their relapses by the end of the second year of infection, and those of Rosahn,³ who recorded 86.7 per cent over a similar period of time in inadequately treated patients.

Although infectious relapse is largely a phenomenon of the first two years of infection, a not insignificant number of instances of relapse after two years have been reported. Stokes, Besancon and Schoch¹ cited a case of infectious recurrence in the mouth six years after onset of the disease, and of the finger nine years after the initial lesion. Nielson⁴ recorded the finding of *Spirochaeta pallida* in lesions that appeared nine years after infection. Hudelo and Rabut⁵ cited two cases of infectious lesions six and seven years respectively after the onset of the disease. Cassar⁷ observed a monorecived or recurrent chancre three years after the appearance of the original chancre. In the Cooperative Clinical Group material of 5,952 cases there were thirty-three instances of infectious relapse occurring from three to seven years after the infection, and eight instances after more than seven years' duration of the disease.⁸

Within a relatively short period, from July 1, 1937, to Dec. 31, 1938, six cases of infectious relapse occurring two and a half or more years after onset of infection were noted in a rather small group of 120 cases, an incidence of 5 per cent. These patients included a group previously diagnosed as having primary and secondary syphilis who for the most part were urged through active solicitation by the social service staff to return to the Syphilis Clinic of the Hospital of the University of Pennsylvania for reexamination. Only patients whose infection was of two or more years' duration were included in this study. Two of the six cases discovered in this series will be reviewed as representative of this type of late relapse:

REPORT OF CASES

CASE 1.—P. D., a white man, was first seen in the Syphilis Clinic of the Hospital of the University of Pennsylvania Feb. 2, 1928, at the age of 21. A diagnosis of seropositive primary syphilis was made. After he had received seven injections of arsphenamine (3.1 Gm.) and two injections of bismuth arsphenamine sulfonate (bismarsen) (0.4 Gm.) irregularly over a period of ten months, he disappeared from observation for twenty-one months. He reappeared in September 1930 with dark field positive penile lesions. Treatment was again instituted. However, after only two injections of neoarsphenamine (0.75 Gm.) and three injections of bismuth subsalicylate (0.36 Gm.) he again lapsed from observation. In November 1932, twenty-six months after the first relapse, he returned with another dark field positive penile lesion. He was given nine injections of trisodium arsphenamine sulfonate (3.9 Gm.)⁹ and nine injections of bismuth subsalicylate (1.2 Gm.) over a period of two months, only to disappear again from observation. Five months after his last injection he again made his appearance in the clinic with a penile lesion. He received trisodium arsphenamine sulfonate ten injections (4.8 Gm.) and bismuth subsalicylate ten injections (1.2 Gm.) irregularly over a period of six months. After a lapse of four months he returned in April 1934 with another dark field positive penile lesion. As the result of repeated urgings and many visits, he was kept under treatment until March 1936, almost two years, receiving during this time twenty injections of trisodium arsphenamine sulfonate (10.4 Gm.) and twenty-six injections of bismuth subsalicylate (3.12 Gm.) irregularly, plus nonspecific therapy with aolan, fuadin and antimony and potassium tartrate.

In November 1938, ten years and nine months after the infection was first discovered and after a lapse of thirty-one months from his last treatment, he reappeared with dark field positive perianal condylomas and multiple penile indurated ulcers. He stated that he had had similar penile lesions recurrently during this last lapse.

Serologic tests of the blood for syphilis were about as irregular as his clinic attendance. They tended toward early reversal with treatment and toward frequent serologic relapses both during treatment and during lapse of treatment. An examination of the spinal fluid performed in January 1936 gave negative results.

CASE 2.—V. H., a Negro woman aged 23, was first seen in the clinic in June 1932 with perianal condylomas positive under dark field examination. Serologic tests for syphilis were strongly positive on admission, reversed after the sixth week of treatment and relapsed at frequent intervals.

From June 1932 to March 1934 the patient received forty-four injections of trisodium arsphenamine sulfonate (23.4 Gm.) and thirty-five injections of bismuth subsalicylate (4.2 Gm.) quite regularly, followed by ten injections of bismuth subsalicylate (1.20 Gm.) irregularly to February 1935. In February 1936 she reappeared, stating that she had had a "boil" on the vulva which had been cauterized by a private physician to whom she applied for treatment because of abdominal pains. Dark field examination of this cauterized lesion was negative.

In October 1938, six years and four months after her original infection, she again appeared with two small, slightly indurated papular, dark field positive erosions of the labia. She stated at that time that she had noticed "sores" on the vulva on several occasions during lapse from treatment but had not sought aid because they did not bother her. These observed lesions were associated with a serologic relapse; the spinal fluid examination was negative in February 1933.

COMMENT

Infectious recurring lesions appeared in the other four cases from two and one-half to four years after onset of infection.

That the reported cases may represent reinfections is improbable, for not one of them fulfils even the less rigid criteria of probable (grade 2) reinfection as out-

lined by Stokes and his collaborators.¹⁰ The second case reviewed perhaps more nearly falls into a borderline type which satisfies some of the criteria of probable reinfection. However, the occurrence periodically of moist vulvar lesions during the two years of lapse from observation points to infectious relapse rather than to reinfection. The patient was not asymptomatic for at least a year after treatment had been discontinued. This considerably weakens the argument in favor of reinfection. Although one cannot be certain that the lesions as observed by the patient were syphilitic, the probabilities favor this assumption, for the last crop of vulvar lesions, similar in characteristics to those observed by the patient, were found to contain *Spirochaeta pallida*.

Stokes and his collaborators² have shown that early mucocutaneous relapse occurred in 15 per cent of those who received nineteen or less injections of an arsenical and in only 2 per cent of those who received twenty or more injections. Twenty injections of an arsenical with corresponding amounts of heavy metal were regarded as the minimum needed to control the danger that the individual represented to his contacts and to the public. This was designated for statistical purposes as "adequate" treatment. The term "adequate" was by no means intended to be synonymous with sufficient or total treatment necessary but was merely used as a convenient designation for the division of material. It is in this sense that the term is used in the remainder of the paper.

Seventy-eight patients (65 per cent of this series) received, numerically speaking, "adequate" treatment. Five of the six relapses occurred in this group. This curious fact of higher proportion of relapse in the "adequately" as compared with the "inadequately" treated cases is due to the closer observation of the more cooperative "adequately" treated patient and to the fact that the prime relapsing period, the first two years, is excluded by our selection of material. Although the "adequately" treated patients tended to be under fairly close observation during the first two years of infection while under treatment and recent post-treatment observation, the "check-up" periods tended to become spaced further and further with time. The recorded incidence of infectious relapse of 5 per cent in syphilis of more than two years' duration therefore constitutes a minimum percentage. The actual incidence can only be surmised.

Two of the six patients were completely unaware of the existence of any lesions; a third ignored the perianal condylomas and regarded them as hemorrhoids. In other words, in one half of the total number of late relapsing cases the lesions appeared so unobtrusively that they were either unrecognized or minimized by the patient. It is probable, therefore, that these spirochete-containing, banal looking painless lesions may "come and go" more frequently than is generally recognized in ostensibly "late latent" syphilis.

Three of the five cases received "adequate" treatment irregularly. That irregular treatment is notorious in the production of infectious relapse has been noted by many observers (Hoffmann,¹¹ Gennerich,¹² Spence,¹³

10. Stokes, J. H., Cole, H. N., Moore, J. E., O'Leary, P. A., Parran, Thomas, Jr., and Wile, U. J.: Cutaneous and Mucosal Relapse in Early Syphilis and Its Differentiation from Reinfection, *Ven. Dis. Inform.* 12: 55 (Feb.) 1931.

13. Spence, H.: Recurrent Syphilide Simulating Reinfection, *Proc. Roy. Soc. Med., Dermat. Sec.* 9: 96 (March) 1915.

9. Stokes, J. H., and Beerman, Herman: New Arsphenamine Synthetics in the Treatment of Syphilis: A Consideration of Test Procedure and of a New Drug (Triarsen), *Arch. Dermat. & Syph.* 35: 78 (Jan.) 1937.

Frühwald,¹⁴ Harrison,¹⁵ Stokes and Usilton,¹⁶ Dennie,¹⁷ Rosahn,³ Gaté,¹⁸ Tzanck and Cord¹⁹ and others). This type of treatment was very apparent in case 1, in which treatment at no time was regularly given for more than ten weeks. The patient suffered no less than five known infectious relapses in ten years. Irregularity in treatment, even though "adequate" from the standpoint of total number of injections, constitutes an important factor in increasing the incidence in this type of relapse.

In two of the six cases treatment was begun in the seropositive primary stage. This tendency toward mucocutaneous relapse in this stage has been shown by Stokes and his collaborators²⁰ to be higher than in any other corresponding stage of early syphilis. However, as has been pointed out in this Cooperative Clinical Group study, the physician's public health duty demands the earliest possible diagnosis as well as the earliest possible institution of treatment.

Four of six cases showed a tendency toward early serologic reversal; that is, seronegativity by the fourth to the seventh week of treatment. Two of these patients showed a tendency toward frequent serologic relapse. Moore and Kemp¹ have pointed out that, in those cases showing "prematurely negative" serologic reactions for syphilis in early infection, relapse of the infectious type is about five times more frequent than in the average case. It becomes, therefore, extremely important to check repeatedly the individual whose blood serologic reactions for syphilis reverse easily or relapse frequently.

Two of the six patients received "adequate" treatment regularly; one of these continued treatment to the point recommended for "biologic cure." Certainly one is forced to the conclusion that there exists a refractory group, however small, who in spite of "adequate" treatment regularly administered may still suffer infectious relapse.

The purpose of recording this group is to reemphasize the fact that infectious relapse can occur for many years after the original infection and to stress that numerically "adequate" treatment, meaning thereby twenty injections of an arsenical and a corresponding number of injections of heavy metal preparations, does not insure noninfectiousness, especially when given irregularly. No rule is infallible as to the total amount of treatment, nor can any arbitrary period of time be stated as the absolute end point of the infectious stage in a given case. It is therefore urged that the criteria of treatment to "biologic cure" and of five years' observation from the time of the original infection²¹ rather than the minimum of twenty injections of an arsenical and twenty

of a heavy metal preparation, plus two years of treatment and observation,²² be applied in the evaluation of the individual case and its infectious status.

SUMMARY AND CONCLUSIONS

1. Although infectious relapse in syphilis is largely a problem of the first two years of infection, a not insignificant number of cases relapse after this period of time.
2. During the course of examination of 120 patients whose infection was two and a half years or more in duration, six were found to have suffered an infectious relapse.
3. Five of the six patients with infectious relapse received more than twenty injections of an arsenical and a corresponding number of heavy metal treatments. Three of the five received this treatment irregularly.
4. Two of the patients in whom relapse occurred began treatment in the seropositive primary stage.
5. Four showed a tendency toward early serologic reversal.
6. No rule is infallible as to the total amount of treatment or the time that must elapse to render the individual patient continuously noninfectious.
7. When possible, it is wiser to strive for the Cooperative Clinical Group standard of from thirty to forty arsenical and sixty weekly bismuth injections than for the artificial median of twenty arsenical and twenty bismuth injections employed as a statistical evaluation device.

By DR. JOHN L. RICE
Commissioner of Health

One of the most serious obstacles to the eradication of syphilis lies in the fact that even the most modern methods for rendering the disease permanently noncommunicable require a minimum of from eight to ten months of treatment. A therapeutic method which would radically shorten this period and be safe, efficient and not too expensive would go far toward the ultimate conquest of this infection and be of enormous significance in the public health control of syphilis. The present discussion deals with the practical application to medical and public health problems of what began originally as an experiment in pure science—the development along physiologic and pharmacologic lines by Hyman and his associates¹ of a new technic for introducing, with impunity, large amounts of fluids, drugs

and biologic substances by means of the intravenous drip. At Chargin's suggestion, the method was applied for the administration of massive doses of arsenicals in the treatment of early syphilis.

The experiments of Chargin, Leifer and Hyman² in 1933 with this new method of treatment seemed to open a new vista on the horizon of syphilis control measures. Twenty-five patients with recent syphilis were given massive dose chemotherapy with the intravenous drip. At the end of five years a check-up showed that very satisfactory results had been obtained,³ and these warranted a consideration of a much larger study. Expert group judgment was needed. For this reason I appointed a committee of syphilologists and internists to study this problem and to decide whether a more extensive investigation was warranted. The committee concluded that such a study should be undertaken and agreed to sponsor it. With representatives of the health department, this committee has assumed responsibility for the work and has guided the project and assured the greatest care and thoroughness in all its phases. The members include Dr. Charles C. Lieb, chairman, Dr. George Baehr, Dr. Louis Chargin, Dr. Walter Clarke, Dr. Eugene Du Bois, Dr. Harold Thomas Hyman, Dr. John F. Mahoney, Dr. Walter W. Palmer, Dr. Theodore Rosenthal, Dr. Evan Thomas, Dr. Bruce Webster and Dr. John L. Rice. The work of the committee has been made possible by grants from the New York and Markle Foundations and the Friedsam Fund, and through the collaboration of the Mount Sinai Hospital, the New York Hospital, Bellevue Hospital, the United States Public Health Service and the New York City Health Department.

During the period of active treatment the patients were hospitalized at the Mount Sinai Hospital. After discharge from the hospital the patients were assigned alternately to Dr. Evan Thomas at Bellevue Hospital or Dr. Bruce Webster at the New York Hospital for periodic follow-up observation. Dr. John F. Mahoney of the United States Public Health Service made serologic examinations on specimens that were taken at the same time as the routine specimens examined by the department of health. The chemical examinations on arsenic excretion were performed by Dr. Harry Sabotka and Mr. Walter Mann, and the special studies of bilirubin excretion for liver function by a group of three at the Mount Sinai Hospital. The hematologic examinations were made by another group. The department of health has provided cases of syphilis suitable for this treatment and has also, with its personnel, carefully checked and investigated all such patients and carried out necessary follow-up procedures.

If the encouraging results obtained up to now are borne out by subsequent experience, it is likely that the intravenous drip method of arsenotherapy may lead to a radical revision in the management and treatment of early syphilis and improve our control of this most prevalent communicable disease. Aside from the obvious economic advantages to the patient and to the community of an abbreviated and more concentrated therapeutic procedure, the work has a wider public health significance. In a recent article by the members of the Cooperative Clinical Group under the auspices of the United States Public Health Service and spon-

sored by the League of Nations Health Organization, it was stated that "the aim in early syphilis may be crisply defined as, first, the prevention of transmission by treatment and, secondly, the individual cure."

The method which is now under investigation and for which this is a preliminary report appears to offer the possibility of rendering a large proportion of patients permanently noninfectious and, perhaps, of curing them in a very short time, namely from five to seven days. It has the further advantage of protecting the community from infection by hospitalizing the patient during the period when there is the greatest danger to intimate contact. These possible advantages have warranted the department of health in undertaking this research project.

CLINICAL STUDIES

BY DRs. HYMAN, CHARGIN AND LEIFER

In the chemotherapy of syphilis, Ehrlich⁴ originally strove to effect a total sterilization of the infected tissues. The serious and even fatal toxic phenomena that resulted from the administration of the arsenicals in effective spirocheticidal doses led to the abandonment of this and subsequent attempts at massive chemotherapy, in favor of the use of divided doses spread over a period of months or even years.

The concept that these untoward reactions might not be specific to the drug, but rather technical in their origin, arose from the work of Hyman and his co-workers¹ in 1931. These investigators reported that the "rapid intravenous introduction of pharmacologically active or inert chemicals, drugs and biologic fluids may give rise to alarming and, at times, fatal symptoms" ("speed shock"). Thus, in laboratory animals "speed shock" was characterized by a rapid and precipitous fall in blood pressure, usually transitory but occasionally fatal: respiratory distress, manifested either by simple dyspnea, apnea with atelectasis or bronchospasm and noncoagulation of the drawn blood. In fatal instances, such as might be produced with simple saline solutions, autopsies revealed multiple punctate hemorrhages in the viscera, fresh thrombi in the pulmonary veins, and either atelectasis or emphysema of the lungs.

The elimination of "speed shock" was accomplished by the regulation of the velocity of injection through the intravenous drip. With the rate of flow regulated at 2 or 3 cc. a minute, "even highly toxic substances such as anaphylatoxin and histamine could be introduced with complete impunity."⁵

Clinical application of these laboratory experiments resulted in the introduction of intravenous drips for use in the administration of physiologic fluids such as saline solution, dextrose and citrated blood.⁶ As a further extension of this work, it was suggested that potent therapeutic agents might be administered "in doses far greater than at present employed and this without serious damage to the cells of the host." The production of "speed shock" with arsphenamine led to the statements (1) that "there might be an intimate relationship between nitritoid crises and 'speed shock' if indeed these were not found to be identical," and (2) that "the intravenous drip may prevent 'speed shock,'

anaphylactoid reactions, nitritoid and hemoclastic crises." Should certain of the toxic phenomena in massive arsenotherapy prove to be manifestations of "speed shock" rather than the specific effect of the drug molecule, intravenous drip chemotherapy might successfully approach the goal of *sterilisatio magna*.

In 1933 Chargin, Leifer and Hyman² treated twenty-five patients who were suffering from recently acquired syphilis. Over the course of five days there was introduced, by means of the intravenous drip, 4 Gm. of neoarsphenamine. Febrile reactions, toxicodermas and mild gastrointestinal symptoms occurred in the majority of patients. There was no immediate or delayed liver or renal damage nor significant parenchymal lesion other than polyneuritis, which occurred in one third of the patients and was annoying rather than incapacitating. Quantitative urinary studies revealed a satisfactory excretion of arsenic averaging about 20 per cent of the total dose. Nitritoid crises were conspicuously absent.

The effect of massive therapy on the clinical manifestations was rapid and dramatic. At the time of the preliminary report,² eighteen of the nineteen patients who were followed beyond a period of three months became and remained seronegative. One man, who was lost at the end of four months and who had received but 2.9 Gm. of the drug (an amount which we now believe to be insufficient for complete sterilization) remained seropositive. Six patients disappeared from observation immediately on discharge from the hospital. It seemed reasonable to state that there had been demonstrated "the possibility of administering colossal doses of an effective chemical agent without seriously or permanently damaging the cells of the host."²

After five years a second survey of this small group was reported. Five patients never achieved seronegativity. None of these patients were followed beyond the fifth month. The remaining twenty patients all accomplished complete serologic reversal though five members of this seronegative group were not followed a sufficient time for satisfactory observation, since all disappeared before the end of the first year. Fifteen of the seronegative patients were examined on or about the fifth year. Eleven of these had repeatedly negative Wassermann reactions, thus giving assurance that their late clinical course had been wholly and completely uneventful. Four patients required explanatory notes: one man, a hospital orderly, insisted on continuing therapy without our knowledge or supervision. On one occasion, though he had repeated negative Wassermann reactions both before and after, his serum reaction was reported to be 2+ in the blood and the spinal fluid. He presented no clinical manifestations of the infection and at the last visit was completely clear in all respects. A second member of this group was not seen between the end of his first month following treatment, when his reaction was 4+, and a period of four and a half years, when the blood, spinal fluid and teleoroentgenogram were normal. Two patients became reinfected with syphilis. In one instance the evidence was indubitable, in the other highly presumptive, though there was the possibility that this may have been a cutaneous relapse.

At this time³ the conclusions were broadened to include the statements that (a) "primary and early secondary syphilis could not only be cured by the massive injection of neoarsphenamine by the method described but a permanent and complete result was possible though no other therapy was introduced in any other way or at any other time"; (b) the method offered "a means for the rapid and successful eradication of

this dread disease" and "possibly presented a new vision of the syphilis problem for public health officials and legislators."

PROTOCOL

Repetition of this earlier work was made possible through the efforts of Commissioner Rice and the Syphilis Project Committee. Treatment was limited to male patients with primary or early secondary syphilis. Eighty-six men were studied and treated. The average dose of neoarsphenamine was slightly in excess of 4.1 Gm. The average duration of treatment was slightly less than five days.

TECHNIC

As in the previous study, the intravenous drips were set up so that 5 per cent dextrose was administered by the gravity method at a rate approximately 100 cc. an hour. At the end of each hour there was added a solution of 0.1 Gm. of neoarsphenamine dissolved in 50 cc. of 5 per cent dextrose. In turn, this was followed by another hour of the plain dextrose, followed by another 0.1 Gm. of the drug until the total daily dose had been administered. Thus, in a period of fifteen hours a patient might receive 1,500 cc. of 5 per cent dextrose and 1 Gm. of neoarsphenamine. The treatment was usually started at 8 a. m. and continued throughout the day, the needle remaining in situ. The diet was semisolid and rich in carbohydrate.

TOXICOLOGY

Forty-nine patients (57 per cent) experienced primary or Herxheimer fever. The average duration of this fever was slightly over one day and the average height was 102 F. The highest temperature recorded was 105 F. and the longest duration of the febrile reaction was four days.

A secondary fever, usually appearing toward the latter part of therapy or after the termination of the injection, was noted in fifty-four patients (63 per cent). The average duration of this fever was slightly under four days and the average height of the temperature was 102.8 F. The highest elevation was 105.4 F. and the longest duration was ten days. Those with primary fever did not necessarily have secondary fever; similarly, those with secondary fever might not have had the primary fever.

TOXICODERMAS

Toxicodermas were usually associated with the secondary fever. The immediate eruptions were scarlatiniform, morbilliform or erythema multiforme-like in character and occurred in forty patients during the period of hospitalization. An additional group of four patients developed toxicodermas while under observation in the follow-up clinic, so that this complication was present in forty-two patients (52 per cent). One patient developed a desquamation of the skin following a toxic erythema but the process was mild and recovery was rapid. A true dermatitis exfoliativa occurred once and was followed by complete recovery.

It is interesting to note that neither gonorrheal infection nor the virus of the common cold occurring simultaneously with syphilis yielded to these massive doses of neoarsphenamine.

NEURITIS

Peripheral neuritis occurred in thirty-one patients (38 per cent) but none were severely incapacitated. The neuritis developed two or three weeks after discharge from the hospital and lasted as long as from four to six months. There was no relationship between arsenic excretion or retention and the polyneuritis.

KIDNEY FUNCTION

Daily routine urinalyses, blood chemistry examinations on admission and discharge, and concentration tests failed to reveal any significant evidence of renal irritation or damage.

LIVER FUNCTION

Liver function was studied in a routine manner through observations of clinical jaundice, daily examination of the urinary urobilin and estimation of the icterus index on admission and discharge. Four patients developed mild jaundice. In none of these was there any apparent permanent damage. Eight patients showed an increase in the urobilin to more than one tenth at one time or another, but on discharge all were within normal limits. Seven patients showed an icterus index that exceeded 10 at least once during the course of hospitalization, though on discharge the index was significantly elevated in none. An additional five patients showed an icterus index of 15 or more in the follow-up clinic but none developed significant hepatitis.

Bilirubin excretion tests⁷ were performed on ten consecutive and unselected patients. The first test was made before the institution of treatment, and the comparative reading was checked immediately following the completion of therapy. Three of the ten patients showed slight impairment of hepatic function, i. e., retention of 100 per cent or more bilirubin. None of these patients showed any clinical evidence of hepatic damage.

BLOOD COUNT

Complete blood counts were made on admission and discharge. No abnormalities were noted in the erythrocytes or leukocytes.

A hemorrhagic tendency developed five weeks after treatment in one of the early patients. When it was found that he had a thrombocytopenia (5,000 platelets), routine platelet counts were included in the study. It was the original impression that the thrombocytopenia resulted from arsenotherapy in this patient. More careful study by Dr. Nathan Rosenthal, however, led him to the conclusion that this was an instance of chronic idiopathic thrombocytopenia, intensified but not fundamentally caused by the administration of the drug. At Dr. Rosenthal's suggestion a splenectomy was performed, following which the platelets rose and remained normal.

Through a fortunate error there was noted a second interesting observation concerning thrombocytopenia. The routine blood count, which should have been performed before the institution of therapy, was delayed in one patient until just after the first small and diluted dose of the arsenical had been introduced. By this time the platelets had already dropped to 20,000. The injections were immediately discontinued. Five days later the platelets had risen to 200,000. The patient was rejected for further therapy with the arsenicals. Following a routine course of treatment with the other heavy metals, he was readmitted to the hospital. His blood platelets were then 240,000. He was given 0.1 Gm. of neoarsphenamine and again the platelets fell to 60,000. This experience suggests that idiosyncrasy rather than overdosage may be the determinant factor in the production of this as well as other toxicologic phenomena.

CEREBRAL SYMPTOMS

Two patients gave cerebral symptoms that suggested hemorrhagic encephalitis. In one instance, without other antecedent or later difficulties, the patient had a single convulsion. The spinal fluid was normal and the course, otherwise, uncomplicated. In the second instance, death occurred. This man was an 18 year old Negro, admitted with a seropositive primary syphilis. He received 1 Gm. of neoarsphenamine the day after admission. This was followed by a primary fever to 103 F. The next and succeeding two days his temperature was normal and he received 1 Gm. daily on each of these three days. On the last day of treatment, after receiving 0.4 Gm. of the drug, he became nauseated and vomited. Treatment was discontinued, since he had received 4.4 Gm. in all. The next day his temperature was normal, but the following morning, or six days after the beginning of treatment, a toxicodermata was observed. At this time there was no febrile reaction and no other complaint. At 3 p. m. he appeared somewhat dazed and had a tremor of the hands and head pain. At midnight he went into a convulsive seizure followed by stupor. The spinal fluid was clear, was under increased pressure and contained 20 cells per cubic millimeter with increase in the globulin but negative Wassermann and colloidal gold reactions. Despite vigorous treatment the convulsions continued, the temperature gradually rose to 107.4 F. and he died on the third day. All of the various laboratory examinations were normal. No autopsy could be obtained. A careful review of his records and the course of the symptoms during hospitalization failed to reveal any extenuating circumstance. Since this patient and the aforementioned one with the single convulsion were treated simultaneously, the suspicion arose that there may have been some unusual toxicity in the particular batch of the drug employed at this time. Samples were submitted to the National Institute of Health and examined by W. G. Workman, acting chief. No unusual variation from the original assay was found, and the fatality must be recorded as the direct result of therapy.

Cole and his associates⁸ in a series of 1,212 cases observed twelve deaths, of which six were due to hemorrhagic encephalitis. Five of the six patients received four or fewer injections of the average dose of the arsenical. The sixth patient received nine doses. These facts suggest the possibility that hemorrhagic encephalitis, like thrombocytopenia, may result from idiosyncrasy rather than overdosage.

It is noteworthy that nitritoid crises, the various types of atrophy and degeneration of the liver, aplastic anemia and pulmonary embolizations were conspicuously absent as toxicologic phenomena.

ARSENIC EXCRETION STUDIES

The fate of the injected arsenic was followed by quantitative analyses of the total urine and stool specimens collected, during therapy, in twelve consecutive and unchosen cases. Of the 800 mg. of arsenic administered in the course of therapy, 160 mg., or 20 per cent, was excreted in the urine. This corresponds closely with Leifer's experience in our first series,² in which approximately 150 mg. of arsenic was found to be the average excretion over a similar period. It was not possible to do stool analyses in the first series, and the results of the fecal arsenic excretion in the present series was regarded with considerable interest, for it has been

7. Soffer, L. J.: Postarsphenamine Jaundice, *Am. J. Syph., Gonorr. & Ven. Dis.* 21: 309 (May) 1937.

8. Cole, H. N., and others: Arsenical Reactions in Treatment of Syphilis, *J. A. M. A.* 97: 897 (Sept. 26) 1931.

generally believed⁹ that the fecal elimination is higher than urinary excretion. Confirming this view, an average of 260 mg., or 32 per cent, was recovered from the total feces during the course of therapy. Thus, 52 per cent of the injected arsenic was accounted for through urine and stool during the treatment period. It was not possible for us to determine the amounts that may have been excreted through other channels such as the skin.

In a few instances the urine and stool analyses were carried on for several days following the completion of actual therapy. An additional 1.7 per cent was recovered from the urine (ten specimens) and an additional 9.5 per cent from the stool (seven specimens). Thus, in certain of the completed cases as little as 27 per cent of the arsenic was unaccounted for at the end of this brief period.

During hospitalization an average approximating 60 per cent of the total arsenic dosage was recovered from urine and feces, indicating quite clearly that significant retention or accumulation of the drug did not occur.

CLINICAL RESULTS

Rapid healing of both primary and secondary lesions was noted. Dark field examinations invariably became negative within twenty-four hours. The patients were apparently rendered free from infectivity on discharge from the hospital, a significant point in the public health aspect of syphilis control. This is the more striking in comparison with the results in patients treated by routine methods. For example, Cannon¹⁰ observed that in twenty patients using arsphenamine in the routine manner the average time for involution of the chancre was 12.5 days following 3.1 injections. With nearsphenamine the involution of the chancre was 21.3 days after 4.8 injections. Since these patients were ambulatory it follows that, for at least two to three weeks, the syphilitic patient treated by routine methods is a hazard to the community to which he is returned, whereas patients treated by the massive dose technic are probably noninfectious on discharge from the hospital.

An interesting clinical observation in our patients was their sense of well-being. Striking gains in weight were frequently recorded. During therapy patients sometimes ate voraciously. Since most of the patients were recruited from the unemployed and underprivileged, this may not have been wholly attributable to therapy; but it at least emphasizes the point that therapy is not completed at the expense of general nutrition.

EFFECT ON SERUM REACTION

Chargin¹¹ has previously expressed the view that the serum reaction is the most valuable guide for determining the efficacy of any method of treatment in early syphilis. In the present work this was particularly borne out by the amazing sensitivity, accuracy and close parallelism that existed in the results obtained by Senior Surgeon John Mahoney working at the United States Marine Hospital at Stapleton, Staten Island, and Mr. John Koopman, analyzing duplicate blood samples at the Laboratory of the New York City Department of Health.

The technic employed by Dr. Mahoney was as follows:

The reports submitted in this study were produced by the Kolmer quantitative complement fixation technic. The antigen used was the "new Kolmer antigen," the test dose being determined by the titration method of Boerner and Lukens. High titer lyophilic complement was employed and the natural anti-sheep hemolysin was removed from the serums through the use of washed sheep's blood cells. Serum dilutions of 0.2, 0.1, 0.05, 0.025 and 0.005 cc. were used and the degree of inhibition of hemolysis indicated by the conventional numeral method for each dilution. In all details of technic there was strict adherence to the procedure recommended by the originator of the method.

Readings varied from 00000 to 44444.

The technic employed by Koopman is as follows:

The antigen used was prepared by alcoholic extraction of dried beef heart. The alcoholic extract, after evaporation, was mixed with an equal portion of acetone. The acetone insoluble fraction was redissolved in alcohol and 0.2 per cent cholesterol added. To each of twelve tubes were added 0.1 cc. of the patient's serum, 0.1 cc. of antigen, 0.2 cc. of salt solution and increasing amounts of complement, the first tube receiving 0.1 cc. and each succeeding tube receiving 0.05 cc. additional until the last tube contained 0.7 cc. The tubes were then permitted to stand at 6 C. for eighteen hours, after which 0.3 cc. of sensitized cells was added.

If complete fixation occurred in the first tube, the serum was given a value of 4+; a value of one (1) was then added for each of the other tubes that showed complete fixation, so that the maximum reading was 15+. If the reagin titer was reduced to the point at which the first tube showed incomplete fixation, 0.02 of serum was used in order to obtain readings of less than 4+. This quantitative test, as employed by Koopman in the drip cases, was more sensitive than the routine test used in the New York City Department of Health.

The Mahoney and Koopman serologic studies subject these patients to most highly sensitive tests. The test was repeated at first every two weeks and then every month.

LOST FROM OBSERVATION

Seven patients (42, 46, 47, 64, 68, 70 and 84) failed to report to the follow-up clinics after discharge from the hospital.

DEATH

One patient (80) was the unfortunate Negro who succumbed to a hemorrhagic encephalitis immediately following treatment.

FAILURES

The course in four cases has been clinically or serologically unsatisfactory:

Two of the men (14 and 76) had cutaneous relapses. The first of these may possibly have been reinfected, since his wife showed evidences of active syphilis. In the absence of complete evidence of reinfection, however, he will be reported as a failure so that in this instance, as in all others, the results might be reported with the utmost conservatism.

Two patients (52 and 66) showed serologic relapse. In each instance the present titration of reagin is at the admission level. The spinal fluid and clinical examinations are normal and further treatment is being withheld, for there still exists a remote possibility that seroreversal may yet occur.

PENDING CASES TENDING TOWARD SEROREVERSAL

A trend toward seronegativity is occurring in seven patients whose bloods have not yet completely cleared.

Patient 4 is completely normal in the Kolmer titration, but the Wassermann is still 1+ at fifty-eight weeks. The spinal fluid and physical examinations are normal. This patient had a splenectomy at his twentieth week because of an idiopathic thrombocytopenic purpura.

9. Underhill, F. P., and Davis, S. H.: The Excretion of Arsenic After Serial Administration of Arsphenamine and Nearsphenamine, *Arch. Dermat. & Syph.* 5: 40 (Jan.) 1922.

10. Cannon, A. B.: Outline of Treatment for Syphilis, *New York State J. Med.* 39: 70 (Jan. 1), 145 (Jan. 15), 254 (Feb. 1) 1939.

11. Chargin, Louis: Antisyphilitic Therapy, *J. A. M. A.* 76: 1154 (April 23) 1921.

Patient 38 presents an obstinate serum reaction in which, after forty-four weeks, the Wassermann has been reduced from 12+ to 4+ and the Kolmer from 44444 to +0000. The spinal fluid is normal and the recent progressive changes in the tendency toward seronegativity give promise of a late clearing.

Patient 49, not observed after his discharge from the hospital for almost nine months, had an admission Wassermann reaction of 4+ that has been reduced to 0 and an admission Kolmer of 44444 that is now 43100 with completely negative spinal fluid.

Patient 59, whose highest Wassermann reaction was 12+ and Kolmer 44444, at thirty-nine weeks, has now a 1+ Wassermann and a normal Kolmer.

Patient 71 entered the hospital with a Wassermann reaction of 6+ and a Kolmer of 44444. At eight weeks the former was \pm and the latter 11000. The patient was not again seen by us but eighteen weeks after his discharge from the hospital, and ten weeks after his last serologic observation, he appeared at the Charles V. Chapin Hospital in Providence, R. I., with a fresh sore on the penis that was located in an area different from the previous scar. Dark field examination was positive. He gave a definite history of exposure. The blood Wassermann reaction was negative in the alcoholic antigen and \pm with the cholesterinized antigen. His spinal fluid was normal. There is abundant evidence, therefore, for regarding this as a reinfection but again, in the interests of conservatism, we are reporting the case among those which are questionable. Routine therapy was instituted for this patient. It is interesting to observe that, despite the fears of sensitization to arsenic, no unusual toxicologic phenomena developed during the second course of treatment. This was the experience with patient 14, reported as having a cutaneous relapse, who received a second course of massive dose therapy.

Patient 79 at his last observation, at eighteen weeks, had a Koopman Wassermann reaction that had fallen from 13+ to 5+, and a Kolmer that had been reduced from 44444 to 443 ± 0 .

The last patient (86) in the pending group of seven entered the hospital with a Wassermann reaction of 10+ and a Kolmer reaction of 44444. His spinal fluid showed a 4+ routine Wassermann reaction, 11 cells, a globulin of 4+ and a colloidal gold of 55544332211. He has now been observed for forty-four weeks. The spinal fluids, taken at the end of two and six months, are normal. The blood Wassermann reaction has been reduced to 4+ and the Kolmer to 1 ± 000 . Both clinical and neurologic examinations are completely normal.

Of these seven patients tending toward seroreversal, none show any evidences of their infection other than a slight and reduced amount of reagin in the blood. It is not unlikely that further observation will show complete clearing in some, at least.^{11a}

COMPLETE SEROLOGIC REVERSAL

Sixty-seven patients are already completely seronegative. This constitutes 86 per cent of the surviving patients who were adequately followed, including those who are still pending, and 94 per cent of the survivors excluding, for the time being, those patients who are still pending.

The composite picture of the seronegative group shows that the admission Wassermann reaction was 8+, the Kolmer 44442, the average time for the achievement of seronegativity slightly over twelve weeks, the average number of negative blood tests 6.7 and the average span of observation to date forty-five weeks. Fifty-seven patients have had normal spinal fluid examinations, the majority having been taken between the eighth and the twelfth month.

11a. In the four months that has elapsed since the preparation of this paper, three of these pending cases have become completely seronegative: Patient 4, now in the seventy-fifth week of observation, has had four examinations of his serum without any evidence of any reagin since the sixty-second week. Patient 59, now in the sixtieth week of observation, has had three blood examinations showing complete negativity, and one negative spinal fluid. Patient 86, whose spinal fluid was positive on admission to the hospital and now in the sixteenth month of observation, became seronegative at fifty-two weeks and now has had four normal blood examinations, as well as a normal spinal fluid.

There still exists the possibility that there may be added to this group of satisfactory cases some now in the group of seven reported as pending cases tending to seroreversal.

With three exceptions, these patients have been observed for six months or more. As many as thirteen negative reports have been received on a single individual and but two patients have fewer than three completely normal readings.

These results, of course, are not to be interpreted as final. As time progresses it is our intention to present a further study, and Commissioner Rice has arranged, through the agencies interested in this work, to provide adequate funds for several years of detailed study. As in the previous report, no conclusion can be ventured at this time beyond the statement that the massive dose method of arsenotherapy by the intravenous drip method is capable of producing a serologic reversal in the vast majority of patients under observation. The later course of these patients, the possibility of serologic or clinical relapse, cannot now be hazarded. However, the five-year results³ on the previously reported small group might give rise to the conjecture that no important or significant sequelae are to be anticipated.

The serologic results have been retabulated according to the duration of infection preceding treatment. While the histories are not always wholly reliable, fifty-four patients, of whom we have complete records on forty-six, sought treatment within eight weeks of infection. All are seronegative on an average of ten weeks or less and the average of the highest Koopman titration approximates 7+.

These figures indicate that the sooner the patient seeks treatment the lower the titration of the Wassermann reaction; the lower the Wassermann titer, the more rapid and sure will be the achievement of seronegativity.

The thirty-two remaining patients did not seek treatment until the infection was present for eight weeks or more. All of the unfavorable cases are included in this later group, illustrating again the importance of early treatment. However, twenty-one of these late cases achieved and maintained seronegativity. Whereas in the early group this occurred at about the tenth week on the average, in this group it did not occur until approximately the sixteenth week. Similarly, the Koopman titration checked on the history of prolonged infection and served in a prognostic sense, for the average was 11+ as opposed to 7+ in the earlier series.

These results may have prognostic significance, for they suggest, even in a series so small, that massive dose chemotherapy may reasonably be expected to affect a complete and rapid serologic reversal provided the duration of the infection is eight weeks or less and the Koopman titration does not exceed 7+.

COMPARISON OF THE LATE AND EARLY SERIES

It is possible now to compare the toxic phenomena and the early clinical observations in the original twenty-five patients and the present group of eighty-six.

(a) *Toxicology*.—In neither group was a nitritoid crisis observed. Primary fever was present in 80 per cent of the first and 57 per cent of the second series. Secondary fever was present in 68 per cent of the first and 63 per cent of the second group, the toxicoderma being present in 32 per cent of the first and in 52 per cent of the second series. In the second series 200 mg. daily of vitamin C was administered orally during

therapy, since it had been reported¹² that vitamin C protects against these particular toxic phenomena. Our work does not indicate that the administration of vitamin C is of value as a prophylactic against the secondary fever and toxicodermas. Polyneuritis was present in 32 per cent of the first and 38 per cent of the second series. In the second series the patients were treated daily with 6,000 units of vitamin B into the drip and 1,200 units daily by mouth thereafter during the hospital stay. It had been suggested that vitamin B might protect against chemical polyneuritis but this hope is not confirmed by our experiences. The therapeutic use of vitamin B as practiced in the follow-up clinics after the development of polyneuritis similarly seemed not to affect the course of this complication.

Significant renal or hepatic damage was not observed in either series. No late parenchymal damage was experienced. The single dire complication that arose was the fatal case of hemorrhagic encephalitis occurring in the second and larger series.

The toxicologic phenomena in the two series were therefore quite parallel, the discrepancies probably being due to the factor of chance that will necessarily enter in any small series.

(b) *Clinical Results.*—The immediate clinical results were remarkably parallel in the two series. Infectivity was of short duration, the spirochetes disappearing from the lesions within twenty-four hours. Serologic reversal was obtained in approximately 90 per cent in both groups.

Of the completed cases there are but five acknowledged failures. In the first group there was one patient with inadequate therapy (2.9 Gm.) and persistent seropositivity at his last visit at four months. In the second group there were two clinical relapses and two serologic relapses. Thus far in neither group has there been any other manifestation of syphilis. The original group of twenty-five followed over the course of five years showed no late tendency to relapse either clinically or serologically. Normal spinal fluid and cardiac condition gave further assurance that sequelae had been averted. The close parallel that exists between the two series of cases in the early experience gives promise that equally favorable data will be obtained in the late observations of this current group.

SUMMARY

The massive dose method of chemotherapy in early syphilis, apparently, yields immediate clinical and serologic results that equal the best results that are obtainable by the optimal methods of routine continuous treatment. In fact, there is more than a suggestion that our results, obtained without the use of bismuth and mercury compounds, excel the best reported results that come from the most eminent syphilologists working under optimal conditions.

We are not yet satisfied, however, that the factor of toxicity cannot be greatly reduced. Our experiences with the febrile reactions, the toxicodermas, the neuritides, and particularly the fatal incident due to hemorrhagic encephalitis, have made us emphasize again that this method of treatment must still be considered in an experimental phase and should not be employed for routine clinical use until greater safeguards have been established. Vitamin therapy, both for prophylactic and for curative purposes, has proved ineffectual in the management of the toxicologic phenomena.

Massive dose chemotherapy, if it proves safe, practicable and effective, holds out the possibility of greater convenience, greatly shortened period of infectivity, removal of the syphilitic person from circulation during his active months, and a course of therapy to be measured in days rather than months. It is too soon to judge of the ultimate effect of the method, though the small group of cases followed for a period of five years appear to be clinically and serologically cured.

ABSTRACT OF DISCUSSION

DR. R. A. VONDERLEHR, Washington, D. C.: Every new method for the treatment of syphilis described by reputable investigators deserves the most careful study. While modern therapeutic methods are effective if generally applied, they are expensive and inconvenient for the patient. The medical and public health professions cannot, however, accept either new methods or new drugs for the treatment of syphilis without subjecting them to the most intensive and critical investigation. Those in the Public Health Service in charge of the control of syphilis feel that any new method or drug advocated must meet the following requirements before it can be accepted as an equal of the continuous alternating scheme of treatment described by the Cooperative Clinical Group: 1. The new method must be as actively spirocheticidal as the continuous alternating method of treatment with the arsphenamines and must heal open lesions as quickly. 2. It must prevent the communicable forms of relapse with the same degree of efficiency. 3. It must prevent the late crippling manifestations of syphilis to the same extent. The evidence presented by the authors indicates that the intravenous drip method does bring about rapid healing of the open lesions. Whether it prevents mucocutaneous relapse is not finally established. The indications are that communicable relapses occur in a somewhat higher percentage of the patients treated with the drip method than with the continuous alternating scheme, although statistical study of present figures shows that the difference is not significant, owing to the dearth of patients treated by the former plan. It has not been possible for advocates of the intravenous drip method to obtain sufficient information regarding its ability to prevent the late crippling manifestations of syphilis because sufficient time has not elapsed since the procedure was first used. Toxic reactions to the antisiphilitic drugs with the two schemes of treatment must also be considered. The untoward effects resulting from treatment with the intravenous drip method cannot be compared with material which has been published by the Cooperative Clinical Group because in the former instance the reaction rate is based on the number of patients treated and, in the Cooperative Clinical Group material, on the number of reactions per thousand injections of drug. When a larger number of patients have been treated by the drip method, so that the material becomes more significant statistically, the reaction rate should be compared on the same basis. I am prepared to offer the cooperation of the Public Health Service in a study of this kind, should the authors desire it.

DR. GEORGE V. KULCHAR, San Francisco: I have been interested in the development of the massive intravenous drip method and the methods that have been developed abroad for massive therapy in syphilis. It closely approaches our ideal, but the high incidence of reactions evidenced by Dr. Chargin, Dr. Hyman and their associates, and that observed by Tzanck in Paris would indicate that this method should be approached with care. There may be some method by which these abnormally frequent undesirable reactions, particularly hemorrhagic encephalitis, might be avoided. Dainow in France has been able to detoxify the arsphenamines by the addition of ascorbic acid, and I wonder whether this has been tried by the authors. If it should be applicable, the addition of ascorbic acid to the solution might be efficacious in preventing hemorrhagic reactions. Ascorbic acid, as you know, is concerned with the maintenance of vascular permeability, which is the pathologic lesion in hemorrhagic encephalitis. I would be interested in hearing Dr. Hyman discuss this point.

¹² Dainow, I.: Relation of Vitamin C to Intolerance to Arsenobenzenes, *Presse méd.* 45: 1670 (Nov. 24) 1937.

DR. EARL MORRIS, Hays, Kan.: The point of technic was mentioned. How do they get around the atopic effect of having the drug made up a fairly long time? How long is it safe?

DR. HAROLD T. HYMAN, New York: As to the effect of ascorbic acid on the toxic manifestations secondary to arsphenamine therapy, we have given adequate doses of vitamin C without observing any perceptible favorable effect. I regret that the work of Tzanck has been brought into the discussion. I hoped not to have to mention it. Following the publication of our work in France, Tzanck initiated his so-called week-end treatment. The work has been badly controlled, early cases were not chosen, the patients apparently were incompletely examined. Following the week-end course in which Tzanck used exactly our dosage and our technic, though he denied knowledge of our published work, his patients received a course of bismuth injections and, in many instances, a second and even third "week-end treatment" with neoarsphenamine. We believe that the work was reckless and uncontrolled. Already he has published records of two deaths. We do not wish our work to be confused with his. In answer to a written question from Dr. Wilbur, the rate of administration is about 100 cc. per hour. The drip is put on at about 8 a. m. and the patient usually has had the completed dose by 5 or 8 p. m. At this time the drip is discontinued and the patient is free to carry out normal activities. To prevent oxidation, the neoarsphenamine solution is made up 1 decigram at a time and immediately administered.

THE EXANTHEM OF ACUTE MONONUCLEOSIS

H. J. TEMPLETON, M.D.

AND

ROBERT T. SUTHERLAND, M.D.

OAKLAND, CALIF.

In view of the increasing frequency of the recognition of acute mononucleosis and its occasional occurrence in epidemic form, we have felt that it would be worth while to describe further the exanthem that occasionally occurs with it. We are not the first to do so, as Tidy,¹ Lyght,² Sadusk³ and Isaacs⁴ have mentioned the eruption in articles on the disease.

THE DISEASE

Acute mononucleosis has been known since Pfeiffer described it in detail in 1889 and called it "glandular fever." In brief, it may be described as an acute infectious disease occurring usually in young people and characterized clinically by malaise, fever and glandular swellings. From the laboratory standpoint there is a characteristic blood picture and agglutination test. The typical case begins acutely with sore throat, general malaise and aching, fever and sometimes nausea and vomiting. There is a generalized lymphadenopathy, but the cervical glands, particularly those in the posterior triangle, are most commonly involved. The spleen is quite commonly enlarged. The fever is generally of a moderate degree and may last from a few days to several weeks. Some cases of mononucleosis present an initial leukopenia, a rising temperature, an enlarged spleen, abdominal pain, and a rash suggesting rose spots. Such cases may sometimes be confused with typhoid

until further laboratory work confirms the diagnosis. Complications practically never occur. Convalescence varies greatly and may be prolonged and characterized by weakness. There is another type of glandular fever in which the onset is more insidious, the symptoms are less acute and the febrile period and lymph node enlargement more prolonged.

LABORATORY EXAMINATION

Two laboratory procedures are characteristic and diagnostic: the blood picture and the heterophile antibody agglutination test. The typical blood picture is that of leukocytosis associated with a marked mononucleosis. The total white blood count generally ranges from 10,000 to 20,000. The mononuclear cells constitute from 60 to 90 per cent of the total cells. Lyght² has shown that the total white cell count and the degree of the mononucleosis are directly proportioned to the height of the patient's fever. Return of the count to normal is rather slow, often being delayed for several weeks. We know of a physician whose count did not return to normal until months later. The agglutination test depends on the existence in this disease of heterophile antibodies which produce agglutination of sheep corpuscles. Another finding of considerable significance is the presence of fenestrations of the cytoplasm of the mononuclear cells.

THE ERUPTION

A careful review of the textbooks on dermatology and general medicine as well as the current literature failed to disclose mention of an eruption in this disease except as will be mentioned.

Tidy¹ says:

There is no characteristic eruption constant for all types. In the glandular and anginose types eruptions are rare—especially among children between 6 and 15 years of age. Urticaria occasionally develops. Amongst younger children and infants eruptions are more frequent and variable, and may be urticarial, erythematous or rubelliform.

Character of Eruptions.—There are two important types: (1) a macular eruption in the febrile type and (2) a rubelliform eruption, mainly in young children. In the febrile type, in the English 1930 epidemic, the rash was a prominent feature and present in the majority of cases. It usually was referred to as a maculopapular or roseolar eruption and closely resembles enteric. It has been described fully in the section on the febrile type. It is rare in childhood. In the ordinary course it fades before the glands become palpable; this is almost invariably so in adults. The rubelliform eruption occurs mainly among young children. It may appear at the onset, before or with the glandular enlargement or later in the attack. Glanzmann is convinced that in many cases it is indistinguishable from rubella, and also that the occipital glands are frequently enlarged. As in rubella, the eruption may be confluent in parts and discrete in others. Other authorities describe it as scarlatiniform.

Eruptions may develop which have been variously described as urticaria, erythema nodosum or morbilliform. These are usually transient. Rolleston saw a case diagnosed as typhus. Goldman observed absolute lymphocytosis in a case diagnosed as chickenpox. Herpes labialis has been recorded many times. I have never seen it in the ordinary glandular type.

Lyght,² in describing 100 cases seen in the student health service of the University of Wisconsin, reports that 5 per cent of his patients developed a rash. We repeat his description:

The rashes mentioned were in general of a fine, discrete, pinkish red maculopapular or macular type, confined mostly

2. Lyght, C. E.: Infectious Mononucleosis, *Journal-Lancet* 58: 91 (Feb.) 1938.

3. Sadusk, J. F., Jr.: Temporary Positive Kahn and Wassermann Reactions in Infectious Mononucleosis, *J. A. M. A.* 112: 1682 (April 29) 1939.

4. Isaacs, H. J.: Infectious Mononucleosis, *Illinois M. J.* 71: 161 (Feb.) 1937.

to the trunk, neck, proximal parts of the extremities, and less frequently seen distally on the face. Two were reddish brown in color and two purplish red. Three were truly urticarial, two frankly purpuric, three mildly pruritic, and two showed some tiny vesicles scattered among the maculopapules. No pustules were observed. The rashes described best fell within the category of so-called toxic dermatitides, if a descriptive term is to be attempted that will give a reasonably accurate picture of the exanthems seen. It should be understood, however, that no two of the rashes were identical.

Sadusk³ reported another case associated with an eruption as seen in German measles. He said: "On admission there was observed a rather faint morbilliform eruption over the neck, chest, abdomen, upper part of the back and in the right antecubital fossa." He remarked, "On admission the case was regarded as one of German measles."

Isaacs⁴ stated that in a few cases maculopapular cutaneous rashes were present.

Our hospital records among students at the University of California show a total of ninety-one cases of acute mononucleosis. Of these seventeen, or 18.5 per cent, presented an associated eruption. It was not until we had observed a number of eruptions on our patients and had labeled them "toxic" that we began to realize that the incidence was strikingly high. We were chagrined at having made a clinical diagnosis of German measles in several of our cases which were later proved to be infectious mononucleosis with positive agglutination tests and characteristic blood counts.

It is difficult to give a composite description of the rashes seen on our patients. They were, in general, of a fine macular character with occasionally a certain papular element present. The trunk was most frequently involved, with the face running a close second. Probably the best description one could give of these rashes would be to say that they were often practically indistinguishable from German measles. Twelve of the seventeen instances of eruption seen by us were of this type. The other five were less characteristic, consisting of multiform lesions or of a slight erythema of the face or abdomen. Itching was mild or absent. The eruption appeared at no regular period of the disease, being first noted anywhere from the third to the twentieth day. They lasted from three to seven days and faded without desquamation.

CRITICISM

Since most of these patients had received some drug or other (frequently a barbiturate) such as is given for symptomatic relief of febrile diseases, it might fairly be maintained that some of the eruptions were due to these drugs. This we cannot deny. However, very few such eruptions have occurred following the administration of the same drugs to far more patients who were hospitalized because of such diseases as influenza and infections of the upper respiratory tract. Therefore we feel that the great majority of these eruptions must have been independent of drugs and due directly to the acute mononucleosis.

SUMMARY

Seventeen instances of eruptions were observed in a series of ninety-one cases of proved acute mononucleosis.

Twelve of the seventeen cases were practically indistinguishable from the rash of German measles. Five were less specific.

Acute mononucleosis frequently presents a morbilliform eruption as an outstanding objective symptom.

3115 Webster Street.

DYSPNEA OF SILICOSIS: WHAT CAUSES IT?

LEWIS GREGORY COLE, M.D.

Director of Silicotic Research, John B. Pierce Foundation
AND

WILLIAM GREGORY COLE, M.D.
NEW YORK

Dyspnea, or the labored breathing of miners' phthisis, as it was called, was well known to patient and doctor alike long before the word silicosis was coined.

The crux of the problem of what causes the dyspnea of silicosis is well illustrated and described in figures 1 and 2 with their elaborate captions.

Dyspnea is the outstanding symptom of silicosis, yet in our opinion it has not been accounted for by hitherto recognized pathologic changes. Dyspnea is the prime factor that incapacitates the worker for hard labor and subsequently for any labor, and it is dyspnea that eventually terminates the victim's sufferings, yet dyspnea is singularly absent in many cases of well marked silicosis in which there are classic roentgenographic signs. It is universally conceded that small, hard, dense nodules in the lung are pathognomonic of silicosis, yet these small, hard, dense nodules are either absent or relatively infrequent in some cases of advanced silicosis in which dyspnea is an outstanding symptom. These silicotic nodules as observed roentgenographically often progress to an extreme stage before they cause dyspnea, yet dyspnea may occur and terminate fatally without a preponderance of the typical well defined nodules. Spherical whorls or nodules are considered pathognomonic of silicosis, yet we believe they constitute a protective mechanism—a constructive rather than a destructive process—and are not responsible for the outstanding symptom of silicosis: dyspnea.

Advanced silicosis is frequently found only by accident, when the patient is being examined roentgenologically for some other lesion or injury, such as a fractured rib. Such accidental discoveries are frequent, but, on the other hand, roentgenograms may show no evidence of typical nodulation even in a case of advanced silicosis such as the one illustrated in figure 2, and the one reported by Chapman.¹ A sandsoap worker died after a short illness, and on microscopic examination of the sections, the younger Mallory confirmed the roentgenologic evidence by reporting that the small, hard, dense nodules, considered pathognomonic of silicosis, were so overshadowed by other types of morbid changes that it was difficult to find them. Through the courtesy of Dr. Mallory of the Massachusetts General Hospital we had the privilege of seeing and studying the sections in this case and of confirming his observations. Certainly the very few nodules present were not the cause of the dyspnea from which the patient died. Typical silicotic nodules were inconspicuous in the West Virginia cases and also in some of the South Jersey cases.

If nodulation is not the cause of dyspnea what does cause it? In this article we will consider in detail three causes of the dyspnea of silicosis, but before proceeding we must consider the three types of silicosis which have been previously recognized and described:^{1a}

Peribronchial silicosis: chronic silicosis without typical nodulation and without dyspnea (Pancoast).

1. Chapman, E. M.: Acute Silicosis, *J. A. M. A.* 98: 1439 (April 23) 1932.

1a. The text of this article was submitted in December 1938, and since that time our investigations have led us to add a fourth type of pneumoconiosis to those enumerated above. This type will be described in articles published almost contemporaneously with this one.

Nodular silicosis: chronic silicosis with typical nodulation, with or without dyspnea (South Africa).

Acute silicosis: acute silicosis without typical nodulation but with extreme dyspnea (Macdonald, Piggot and Gilder; Chapman).

By setting these types up one against another we are making no claim to originality.

Peribronchial or perivascular silicosis was roentgenologically recognized by Pancoast.² It is evidenced by peribronchial and perivascular deposits of collagen caused by small amounts of silica, or silica in combination with other elements, inhaled over a long period, and it may be evidenced further by an overdistention of the blood vessels. This type of lesion is frequently observed in subjects exposed to small amounts of silica, who may live to a ripe old age without dyspnea and die of some other disease but who in the meantime have peribronchial, perivascular lesions in the lungs even though they may not be, and in my opinion should not be, considered of a type that is "within the law."³

Fig. 1.—Illustration lent by Dr. Edward Klein of Perth Amboy, N. J. Exposure to silica in vitreous brick works. Both lungs are literally shot full of silicotic nodules composed of collagen whorls. The nodules are more or less discrete, but there are three massive groups in the right midlung field which resemble a pawnbroker's sign. This patient, however, had no dyspnea. As a matter of fact he had no symptoms, and it was led to the x-ray examination. The patient as well as every one else was surprised at the extreme degree of silicosis revealed. Since this patient had no dyspnea and yet did have marked nodulation in both lungs, it is evident that nodulation is not the cause of dyspnea.

Nodular silicosis is the common and universally recognized type of silicosis and is caused by a more intensive exposure to silica dust than is the peribronchial type. Nodular silicosis was defined by the Industrial Hygiene Committee of America⁴ as "a disease due to the breathing of air containing silica, characterized anatomically by generalized fibrotic changes and the development of miliary nodulation in both lungs; clinically by shortness of breath, decreased chest expansion, lessened capacity for work, absence of fever, increased susceptibility to tuberculosis (some or

all of whose symptoms may be present) and by characteristic roentgen ray findings. The disease is divided arbitrarily into first, second and third stages for convenience of description and possible compensation purposes."

Acute silicosis was described first by Macdonald, Piggot and Gilder⁵ and later by Chapman.¹ We believe that it is manifested by a thickening of the walls of the alveoli. In some regions this thickening is caused by the laying down of small deposits of collagen, whereas in other regions it is caused by capillary dilatation. This type of silicosis is caused by an intensive exposure to silica or to silica in combination with other elements, probably alkaline elements. It terminates fatally within a short time and is therefore referred to as acute silicosis.

After making an intensive study of the pathologic changes of acute silicosis, we are convinced that dyspnea is caused by morbid changes in the blood and endothelial reticular structures, which in turn result in

Fig. 2.—Illustration lent by Dr. Leonidas Harless of Gauley Bridge, W. Va. Exposure to intensive silica dust for twenty months. In this roentgenogram there is not a single shadow that could be definitely interpreted as due to a silicotic nodule. The roentgenologic appearances consist of a general haze or cloudiness of both lung fields, more marked at the right apex. Even those with great experience in the interpretation of roentgenograms of silicotic cases considered that roentgenograms similar to this were not due to silicosis because of the absence of the typical nodulation on which the diagnosis and definition of silicosis are based. Yet at the time of this examination the patient was in the late stages of silicosis with extreme dyspnea. Since the roentgenogram of this patient, who was in the last stages of silicosis with extreme dyspnea, manifests no nodulation, it is evident that one can have dyspnea without nodulation, and it therefore follows that nodulation is not the cause of dyspnea. Much of our pathologic evidence is based on a study of microscopic sections obtained from the autopsy in this case.

changes in blood cells, observed in localized regions of the lung. It is these all important but hitherto unrecognized changes which, in our opinion, explain the distressing symptoms of which the patient complains and which finally cause his death. It is our belief that cases of acute silicosis are by no means so rare as physicians have been led to think. Acute silicosis does not become chronic but chronic silicosis may become acute or may have acute exacerbations or an acute termination. The terminal stage of chronic silicosis may exhibit many of the manifestations of acute silicosis. We believe that

3. Bateman, G. C., in a paper read before the National Safety Council convention in which he quoted Dr. Smith, chairman of the Silicosis Appeal Board, South Africa.

4. Gardner, L. U.: Pneumoconiosis, *Internat. Clin.* 2: 16 (June) 1935.

5. Macdonald, G.; Piggot, A. P., and Gilder, F. W.: Two Cases of Acute Silicosis with a Suggested Theory of Causation, *Lancet* 2: 846 (Oct. 18) 1930.

much, acute silicosis is not recognized clinically, roentgenologically or even pathologically as true silicosis, even by pathologists experienced in silicotic work.

In proof of this, we refer to Gardner's⁶ report on the fifteen cases in West Virginia. Here were patients as "dead as door nails" from silicosis who manifested extreme dyspnea in spite of the fact that typical nodulation was not observed either roentgenologically or pathologically. Because of this absence of typical nodulation their condition was not considered the conventional type of silicosis, and Gardner referred to it as "so-called acute silicosis."

Acute silicosis as observed in these cases provided the key to the solution of the problem of silicotic dyspnea. This acute type of silicosis without typical silicotic nodules would surely be missed except by a silica-minded pathologist. We believe that many a patient who dies of acute silicosis is declared by the pathologist

Fig. 3.—A, thumb section slightly larger than the usual thumb nail sections. As reproduced it is the actual size of the section. This is unsatisfactory for scientific study. B, section extending from the hilus to the pleura and composed of three sections mounted on one slide. Such a section enables one to correlate the pathologic observations with the regions in which they are observed.

to have had "unresolved pneumonia" without his even thinking of employing dark field examination of the lung section. This is particularly true if (a) a history of exposure to silica is unknown, (b) the patient was young and the disease of relatively short duration, that is less than two or three years, and (c) nodulation is not the outstanding change observed in the microscopic examination.

There are five regional manifestations of silicosis: (1) hilar, (2) peribronchial, (3) pleural, (4) interstitial and (5) parenchymal. For each of the five regions there are the following five types of pathologic change:

1. Flecks of silica and other foreign elements.
2. Phagocytes, some empty and some laden with silica and other elements.

3. Collagen laid down in patches in various patterns: (a) lamina, (b) whorls, (c) gobs, (d) fine fibrils.

4. Alveolar consolidation, varying in different regions: (a) alveoli may contain or be practically filled with phagocytes, (b) alveoli may contain homogeneous material with a stellate pattern ("cholesterol crystal clefts").

5. Morbid changes in the blood and endothelial reticular structures: (a) changes of the blood within the vessels, (b) changes in the endothelial reticular structures adjacent to the blood vessels.

The first four pathologic changes will be considered in greater detail in subsequent articles. The fifth, changes in the blood and endothelial reticular structures, is of first importance in an understanding of silicotic dyspnea and will be discussed in this article. As mentioned before, we believe that these changes are the chief cause of dyspnea.

An understanding of the normal anatomic and histologic structures of the lung is essential, but a description of these would be a digression from the subject under consideration. We shall simply refer to the bronchial tree as described by Huntington⁷ and the terminal lobe as described by Miller⁸ and describe a little more elaborately the capillary network in the walls of the alveoli, because these are the specific anatomic and histologic structures which are affected in the acute type of silicosis.

The walls of the alveoli are composed of a rich network of capillaries which is very much like the lattice work between two rooms. This lattice, or capillary network, is covered by thin, flat, squamous or shell-like cells of controversial type. These flat cells do not fit perfectly but have chinks between them. Lymphatic channels which have their origin in these chinks extend all the way to the hilus of the lungs, accompanying the blood vessels and bronchi, or those that are located just beneath the pleura may drain into the pleural cavity.

Just a word as to the preparation of the microscopic sections. The vast majority of microscopic sections of silicosis can be covered by a standard square cover glass about the size of one's thumb nail (fig. 3A). Gardner refers to these as "thumbnail sections" and scorns them. One may make a diagnosis of silicosis on the basis of such a section if he is fortunate enough to have it include one or more silicotic nodules, but such sections are useless for a scientific, microscopic study of the disease. To be useful for scientific investigation or even for a simple negative diagnosis of silicosis, the microscopic section should be large enough to include a portion of the lung all the way from the hilus to the pleura.

No matter how big or how well cut such sections are, they are of no use if photographed in black and white. Large sections stained with the conventional hematoxylin and eosin (4)⁹ are also unsatisfactory because of the poor tissue differentiations obtained; the collagen and muscle tissues and many other structures take on the same color, and the red blood cells are scarcely dis-

9. The numbers in parentheses hereafter refer to color photomicrographs. We believe that photomicrographs in black and white are useless to illustrate the pathologic changes herein described, and we are unwilling to submit inadequate proof of the observations made. Photomicrographs which prove these observations are on permanent exhibition at the office of the John B. Pierce Foundation, 40 West Fortieth Street, New York, and may be viewed at any time by appointment. We would welcome also an examination of the original microscopic sections with a record of each change and its position on the slide. We believe that these color photomicrographs are such that they can be projected readily on a screen for lecture purposes.

cernible (5).¹⁰ On the other hand, adjacent serial sections when stained with trichrome give spectacular differentiation of tissue (6), particularly the collagen and red blood cells, and in some regions they are so brilliant that they remind one of a sunrise. We believe that any success we have had is due largely to the use of Masson's trichrome stain, and we are indebted to the late Miss Helen Gregory, technician in the department of surgical pathology at Columbia University College of Physicians and Surgeons, whose services were acquired through the courtesy of Arthur Purdy Stout, professor of pathology.

TYPES OF MORBID CHANGE

If a large, specially stained, microscopic section extending all the way from the hilus to the pleura is observed with a magnifying glass or its image is thrown on the screen (7), one sees the varying types of morbid change in different regions of the lung and notes the various regional manifestations of the disease. Some portions of the picture produced on the screen are as brilliant as the red sunrise in the east (8), whereas other portions are as drab as the morning western sky (9).

The sunrise areas are as red as blood, for indeed it is blood that gives the brilliant red hue to certain portions of the section. The drab sections, on the other hand, are singularly free from blood. In fact, one may examine field after field microscopically without observing a single red blood cell. Strange as it may seem, it was the avascular area, or region of the drab, leaden sky, which became the most interesting portion of the microscopic section. It is also amazing that, while the absence of red blood cells was noted early, it was not until after more than a year of intensive, hour after hour, day after day study of brilliantly stained sections that this observation became significant. Even more surprising is it that when the slides were presented to a silica-minded pathologist and he was asked "What is the matter with this picture?" he too failed to recognize the singular absence of red blood cells.

When the large avascular areas are once noted, it is observed that in certain regions the line of demarcation between the brilliant red sunrise and the drab sky is so clear cut and well defined that half the microscopic field may contain an overabundance of red blood cells while the other half remains drab and almost entirely free from them (10).

The normal alveolar wall, composed of a lattice work of capillaries, contains only a small amount of collagen. Certainly this amount of collagen does not distort, constrict or contract the lumens of the capillaries, and the blood circulates through the capillaries freely. The lumens of normal capillaries are adequate for the transmission or circulation of the red and white blood cells. In these normal capillaries the red blood cells are observed from various angles, some being seen in profile, others full face and others obliquely (11 and 12).

Large microscopic sections of the silicotic lung show three general manifestations of morbid change: (a) avascular areas (9), (b) overvascular areas (8) and

(c) a region of invasion where the relatively normal lung is becoming avascular (10). In general we believe that the most completely avascular areas are in the mid-lung field, that the overvascular areas are adjacent regions, which may extend all the way from the pleura to the hilus, and that the most normal region of the parenchyma of the lung lies just beneath the pleura.

For the sake of simplicity in presenting our observations in these areas and in considering the sequence of pathogenesis in the lesion, we shall take up the third general manifestation first, as observed at the line of invasion, where the more normal portion of the lung begins to become avascular.

The Line of Invasion.—All portions of the lung show marked manifestations of silicosis by a laying down of collagen in one pattern or another. The collagen is laid down in the walls of the alveolus in such a way as to encroach on the capillaries, causing diminution or occlusion of their lumens. It is the presence of this collagen and the manner in which it is laid down in which one is interested. In certain regions of the section the walls of the alveoli may be thickened without completely obstructing the flow of the blood through the capillaries (13), but in other regions, perhaps because of more collagen or perhaps because of the manner in which it is laid down, the capillary circulation is interfered with. The collagen fibrils in the alveolar wall press on or compress the capillaries and diminish their lumens so that the red cells are caught in a traffic jam. That is, one red blood cell gets blocked in transit through a constricted capillary and other red blood cells pile up against it, much as coins are stacked, giving a typical rouleau appearance (14).

There is a film of serum between these red blood cells, so that they resemble a spinal column with the intervertebral spaces occupied by this film (15). If one red blood cell is compressed on one side, wedge shaped, the adjacent red blood cell changes its shape to fit, much as vertebral bodies change in Kummel's disease of the spine. This indicates that the red blood cells have been trapped there for some time.

Individual cells caught in the constricted capillaries are sufficiently aerated by their adjacent alveoli so that they retain their viability, even though they are slightly deformed or compressed, and take the red stain brilliantly. Red blood cells in the arterioles and in the small arteries proximal to the constricted capillaries still retain their normal shape, but they do not take the red stain brilliantly; instead they take a dirty reddish brown color.

At the point where the normal capillaries become constricted in the line of invasion one observes the most interesting and convincing change, a single constricted capillary forming a part of an alveolar wall and a normal-sized capillary filled with a moderate number of red blood cells forming another part of the same wall (16). All the section adjacent to the normally filled capillary is composed of well vascularized tissue, whereas all the section adjacent to the constricted capillary is avascular and may not contain even a single viable red blood cell.

Avascular Areas.—The walls of the alveoli are tremendously thickened—they may be from five to ten times as thick as the normal alveolar wall—and are composed of (a) increased amounts of collagen laid down in small fibrils in the chinks between the flat cells of controversial origin which line the alveoli, or similar deposits of collagen in the spaces around the

10. L. U. Gardner published an intensive study of Fifteen Cases (Pathology of So-Called Acute Silicosis, Am. J. Pub. Health 23:1240 [Dec. 1933]). His article should be studied in conjunction with the observations herein recorded on material obtained from the same source. The sections which we have prepared for some of the subjects who were exposed to the same dust hazard as Gardner's subjects showed pathologic changes so characteristic that when Gardner saw them he said "I know where those came from," indicating that the sections studied represent a good cross section of the fifteen cases on which his report was based.

capillary network (17); (b) large mononuclear cells which predominate over all other elements (18) in the formation of the alveolar wall; (c) phagocytes, some protruding into the lumen of the alveoli while others are entirely within the wall (19); (d) an occasional single cell or small group of red blood cells stained slightly red or pinkish (20) and (e) hypertrophied cells of controversial origin which line the alveoli (21).

The capillaries in the alveolar wall are so constricted or compressed by the adjacent collagen that they are unrecognizable and do not contain a single red blood cell. Red blood cells in the small and large blood vessels all the way back to the hilus in the avascular areas are disintegrated beyond all recognition (22, 23, 24, 25); they appear as reddish brown amorphous material. One may observe field after field without seeing a single vital red blood cell either in the constricted capillaries or in the arteries that supply the region or the veins that drain it (26).

Back close to the hilus at the branching of the larger arteries, one branch is observed to contain this amorphous material of disintegrated blood cells and fibrin, whereas the other branch contains normal red and white cells with only an occasional fragment of amorphous material (27). Such fragments have apparently broken off from the amorphous material. They do not plug the circulation of other red blood cells in the arteries in which they are lodged.

Overvascular Areas.—Overvascular areas (28) account for the brilliant red sunrise and present a direct contrast to the drab avascular areas. The alveolar walls between adjacent alveoli in the overvascular areas are thicker than normal, but they are composed of tissues radically different from those in the avascular areas. 1. The collagen elements are present but they are very scanty compared with the collagen elements in the avascular areas and are less numerous even than in the more normal regions of the section. 2. The thickened wall fails to contain a single cell with the large, brown-stained nucleus, in contradistinction to the abundance or overproduction of such cells in the avascular areas. 3. Phagocytes are singularly absent in the walls of the alveoli, although a few may be observed occasionally in the lumens. 4. The thickened wall contains a tremendous number of red blood cells—eight or ten times as many as normal—which are viable and stain brilliantly red. (Within the lumens of the alveoli there are large flakes of homogeneous material which stain bluish gray, and the alveoli in these regions contain a far greater amount of air than the alveoli in the avascular areas.) 5. The cells of controversial origin which line the alveoli are so thin and attenuated that they are scarcely recognizable. This is in direct contrast with the markedly thick and proliferated cells, many of which are desquamated, in the avascular area.

The capillaries may be dilated to eight or ten times their normal diameter and contain the overabundance of red blood cells just described. This marked increase in the number of red blood cells is the change which renders the overvascular region of the morning sunrise so brilliantly red. The immense dilatation of the capillaries allows far more than the normal number of red blood cells to circulate through the lumens of the capillaries. This is in direct contrast with the traffic jam in the avascular area. The free flow of the red blood cells through the dilated capillaries allows

them to retain their normal shape in contrast to those caught in the traffic jam, where one red blood cell presses on another in such a way as to deform it.

The aeration of the red blood cells as they flow through the dilated capillaries is problematical. Varying quantities of red blood cells are seen in the alveoli adjacent to the dilated capillaries. In some regions there are only a few red blood cells in the alveoli (29), but in other regions the seepage is so great as to fill completely adjacent alveoli, causing an area of hemorrhagic consolidation (30). The red blood cells observed in the dilated capillaries, the arteries supplying them and the veins draining them are viable and take the red stain brilliantly (31, 32, 33, 34).

CAUSES OF SILICOTIC DYSPEA

Theoretically dyspea has been explained by two pathologic factors: (1) nodulation and, later, massive interstitial fibrosis and (2) alveolar consolidation. To these we add a third, capillary obstruction and dilatation.

Nodulation may diminish the lung somewhat, but the fact that nodulation is not the prime factor in the cause of dyspea is shown by two facts: (1) nodulation may be present in extreme quantities without dyspea, as in the case of fractured ribs, and (2) dyspea may be present to an extreme degree without nodulation, as in acute silicosis. When dyspea is present to an extreme degree there may be nodulation, but this may be so slight that the condition has been referred to as "so-called acute silicosis" when described by a silica-minded pathologist. It is true, however, that in an advanced stage of nodular silicosis dyspea may be caused by so-called massive fibrosis which interferes with the expansion and contraction of the lung.

One of the accepted causes of the dyspea of silicosis is alveolar consolidation. This consolidation is caused by a collection of various materials within the alveoli. These may contain or even be filled with (1) phagocytes, either empty or silica laden; (2) a more or less homogeneous, amorphous material, often with a stellate pattern (Gardner's "cholesterol crystal clefts"); (3) red blood cells, sometimes in hemorrhagic consolidation, and (4) hypertrophied, proliferated and desquamated cells that originally lined the alveoli.

Even this alveolar consolidation, however, is caused by capillary obstruction, which interferes with the regular itinerary of the phagocytes, preventing new ones from entering and old ones from escaping. In other words, we maintain that most of the dyspea of silicosis is caused by circulatory disturbance rather than by mere diminution of the ventilation of the lung.

PATHOGENESIS OF SILICOSIS

From an intensive study of the various sections of the jigsaw puzzle, and by the fitting together of these sections, a conception of silicotic pathology has developed which implies the following pathogenesis: Foreign body flecks composed of silica and other elements that have been inhaled are deposited on the walls of the alveolus. Phagocytes mop up these flecks and engulf them—with amebic hospitality. When the phagocyte becomes laden with silica, it works its way through the chinks between the cells lining the alveoli and comes in contact with the walls of the capillary network, and thence it moves along the lymphatic channel, either toward the hilus or toward the pleura. In its progress it leaves a trail in the form of fine

fibrils of collagen. These fibrils compress or contract the adjacent capillaries in the walls of the alveolus, so that the red blood cells have difficulty in circulating through them. Eventually they cause a contraction of a capillary wall, so that a red blood cell becomes caught and others pile up against it, forming the traffic jam referred to. At first these red blood cells find methods of detouring, but finally even the alleys and side streets are so constricted by collagen fibrils that it is impossible to get through. The red blood cells that form the traffic jam remain viable because they are oxygenated by the air in the adjacent alveolus. As the capillaries become obstructed the blood is dammed back into the arterioles and eventually into the smaller and larger arteries all the way back to the root of the lung. The red blood cells in the smaller and larger arteries and veins have died and become disintegrated because they were not located sufficiently close to the alveoli to enable them to become oxygenated. The hypertrophy and proliferation is another contributing pathologic factor accounting for silicotic dyspnea. (The hypertrophy and proliferation of the thin cells of controversial origin lining the alveoli is similar to the hypertrophy and proliferation in the same type of cell when it is exposed by contact to tubercle bacilli. Therefore this phase of the pathogenesis of silicosis resembles an early phase in the development of the miliary pulmonary tubercle.) The avascularizing process occurs in relatively large areas of the lung, and these areas are rendered functionally useless.

While this avascularizing process is going on in certain large areas of the lung, the direct antithesis is occurring in other large areas, which become overvascularized, perhaps as a compensatory process, as evidenced by dilatation of the capillaries. Because of this free circulation of the blood, the red blood cells are normal and viable and take a brilliant red stain, but blood flows through the dilated capillaries in such large quantities that it is doubtful whether it is well oxygenated.

In view of these observations we are convinced, first, that nodulation, the pathologic change on which the diagnosis and definition of silicosis has been based, is not the prime factor in silicotic dyspnea, and, second, that capillary obstruction, either as an entity or combined with alveolar consolidation, as observed in acute silicosis or as an acute manifestation of the late stages of chronic silicosis, is the chief pathologic factor which causes dyspnea. We believe that the dyspnea of silicosis is principally due to occlusion of pulmonary capillaries in large, localized regions of the lung, with compensating capillary dilatation in other regions. In cases of acute silicosis in which there is massive exposure to certain types of silica, perhaps in combination with some other elements, capillary occlusion is spectacularly present. In cases in which the irritant has less silica and a preponderance of other elements, radically different circulatory disturbances have been observed, but these are too extensive and complicated to be included in this article.

These statements have been made after an intensive study of a limited number of cases of silicosis, but circulatory changes seem to have played an important part in one way or another in practically all the cases that we have observed. An analysis of the roentgenologic evidence and an attempt to correlate this with the pathologic evidence has strengthened our conviction that

there are three types of silicosis, as mentioned earlier in this article. A more recent survey seems to indicate also that these types vary in frequency in different localities.

SUMMARY

Dyspnea is the outstanding symptom of silicosis, but it has not been accounted for by hitherto recognized pathologic changes. It is frequently absent in cases of marked nodulation and is, on the other hand, present in cases of indefinite nodulation.

A consideration of silicosis under the three types previously recognized—peribronchial, nodular and acute—aids in the comprehension of this problem. The acute manifestation, as observed in the Gauley Bridge cases, gave the key to this silicotic problem.

Large sections from the hilus to the pleura stained with Masson's trichrome stain were most valuable in enabling us to make the observations reported. Black and white photomicrographs were useless, and hematoxylin and eosin stain was also unsatisfactory.

Large microscopic sections of silicotic lungs show three general manifestations of morbid change: (1) avascular areas, (2) overvascular areas and (3) a region of invasion.

The region of invasion, where collagen constricts the capillaries, is the most important region for intensive study. In the avascular portion, capillary occlusion by external pressure causes a traffic jam of red blood cells, with a damming back of the blood into the arterioles and a lack of drainage of the veins. The blood in the larger vessels in the avascular areas disintegrates. Overvascular areas, where there is immense dilatation of the capillaries and engorgement of the veins and arteries with viable red blood cells, seem to compensate for avascular regions in different portions of the section.

Theoretically dyspnea has been explained by two pathologic factors: (1) nodulation and (2) alveolar consolidation. To these we add a third, capillary obstruction and dilatation.

From a study of microscopic sections we have made certain deductions which constitute our conception of the life history of silicosis at least as it occurs in some groups of cases. We believe that the dyspnea of silicosis is due to capillary occlusion in large localized regions of the lung, with compensating capillary dilatation in other regions.

Most diseases exhibit morbid changes which can be recognized in relatively small sections, for example certain types of neoplasm can be determined by small groups of characteristic cells, but in silicosis there is a vast variety of morbid changes in various portions of the lung. Different varieties of dust result in different types of morbid change in varying regions of the lung.

40 West Fortieth Street.

Beverages in Reducing Diets.—The amount of fluids which stout persons should drink is greater than that which normal people need. When the obese are reducing weight, plenty of water is also needed. They should drink 3 to 5 pints of fluid daily. This amount can be taken without discomfort provided that drinks are spaced properly throughout the day. Most of it should be taken between meals, i. e., before breakfast, about 11 a. m., about 4 p. m. and before retiring to bed. A limited amount, say a tumblerful, at meal times is quite justifiable, since it aids digestion by softening food.—Christie, W. F.: *Ideal Weight: A Practical Handbook for Patients*, London, William Heinemann, 1938.

Clinical Notes, Suggestions and New Instruments

DIABETES MELLITUS COMPLICATED WITH LYMPHATIC LEUKEMIA

REPORT OF A CASE WITH AUTOPSY

JAMES FINLAY HART, M.D.; JAMES R. LISA, M.D., AND
PAUL A. RIEDEL, PH.D., NEW YORK

Diabetes and leukemia are rarely found associated in one case. By 1928 Wright¹ had collected four cases from the literature and added one of his own. In 1936 Elman and Marshall² recognized a terminal acute leukemia in a patient suffering from anemia of the pernicious type complicated with diabetes. Joslin in 1937³ reported six cases in his own practice. We hereby present a case with autopsy of lymphatic leukemia occurring ten years after the onset of mild diabetes.

According to Wright in 1928 three of the four cases then reported were of the myeloid while his case was of the lymphoid type. The case of Elman and Marshall was diagnosed as lymphoid, while Joslin had four of the lymphoid, one of the monocytic and one of the myeloid type. Our case was of the lymphoid type.

In six of the thirteen cases diabetes was known to have preceded the leukemia, and the period ranged from four months to twenty-two years.

Our case represents the sixth on record to come to autopsy.

REPORT OF CASE

Mrs. S., aged 51, was admitted to the New York City Hospital Nov. 26, 1938, for diabetes and lymphatic leukemia. In 1924 she injured her foot and was operated on in Bellevue Hospital. In 1928 a complication set in and she returned to Bellevue to have the leg amputated. At that time diabetes was discovered. After that she went on a fairly strict diet and made periodic visits to a private physician. According to her statement, she never showed sugar in the urine, though her blood sugar was always found to be in the diabetic range. She had never taken insulin.

In March 1938 she had hemorrhages in both eyes and became blind in the right eye with very poor vision in the left. Six months before admission great weakness developed with loss of appetite and a loss of 28 pounds (12.7 Kg.) in three months.

On examination there was a slightly enlarged liver and a spleen that showed a definite increase in size. There was a generalized lymphadenopathy.

There was a consistent fall in the content of hemoglobin from 50 per cent in October 1938 to 35 per cent in January 1939, with a corresponding diminution of erythrocytes from 2.75 to 1.7 millions. The leukocytes always remained high, from 350,000 to 600,000. The lymphoid cells varied from 88 to 100 per cent with some lymphoblasts always present. When granulocytes were found they were sometimes adult and sometimes young. An occasional eosinophil could be seen. The erythrocytes showed microcytosis, anisocytosis and polychromia. Platelets were diminished in number and the color index was between 0.8 and 0.9.

She was put on a diet of 1,575 calories with 150 Gm. of carbohydrate, 75 Gm. of protein and 75 Gm. of fat. December 1 her fasting blood sugar was 93 mg. per hundred cubic centimeters. December 3 and 6 there was sugar in the urine. The fasting blood sugar December 19 was 114 mg. Sugar tolerance tests with 100 Gm. of dextrose done Jan. 9, 1939, were 114, 154, 210, 222 and 182 mg. On the 12th the urine was positive for sugar. On the 14th the diastase of the urine was 6.6 and that of the blood was 3. The blood cholesterol was 143 mg. and the cholesterol esters were 75 mg. per hundred cubic centimeters.

3. Joslin, E. P.: The Treatment of Diabetes Mellitus, Philadelphia, Lea & Febiger, 1937.

January 18 an estimation of glycolysis was done on whole blood kept at room temperature.

Dextrose was found in the urine January 24 and lactose, pentose and maltose were ruled out. She died January 27.

PATHOLOGIC REPORT

Only the pertinent conditions found are reported.

The axillary and inguinal nodes were enlarged, soft and discrete. The general adenopathy was the most prominent sign of the gross examination. The tracheobronchial nodes were slightly enlarged, soft and deeply pigmented with carbon. All the other nodes of the body, aortic, iliac and mesenteric, were enlarged, soft and discrete and the cut surfaces were fleshy and homogeneous. The spleen was greatly enlarged and likewise soft, homogeneous and fleshy in appearance. The heart appeared tigroid. The other organs presented no macroscopic changes.

The glands and spleen presented the same appearance, a diffuse sheet of fairly homogeneous lymphoid cells. Leukemic infiltration was present in the heart, liver and peripelvic renal fat.

Estimation of Dextrose in Whole Blood January 18

Time p. m.	2:30	3:30	4:30	5:30	6:30
Dextrose, mg. per 100 cc.	145	129	121	114	105

The pancreas was completely free of leukemic infiltration. The islands of Langerhans appeared very scanty but those present were quite normal in appearance.

The other organs were normal, the only change being the large numbers of lymphoid cells in the vascular bed.

The anatomic diagnosis was diabetes mellitus and chronic lymphoid leukemia.

COMMENT

At first the history of the diabetes suggested a possibility of error in diagnosis. It was thought that with so few positive urinary specimens in ten years it might not be diabetes mellitus but pentosuria or some other condition of sugar excretion. The diabetic type of blood sugar curve following a dextrose tolerance test, however, established the fact that the carbohydrate metabolism was at fault and more than likely of a diabetic nature. There was no sugar excreted in the urine during the test, and no reducing substances were found thereafter until the diet was raised to high carbohydrate values. The exact amount of sugar intake was difficult to estimate, as she refused many of her feedings and vomited many more. It was only after she was put on an exclusively fruit juice regimen that sugar occurred in the urine. This was shown to be dextrose first by fermentation, which eliminated pentose, and then by Barfoed's reagent, which gave a positive reaction and eliminated maltose. The diagnosis of diabetes mellitus was then confirmed and the degree shown to be mild enough for control by slight restrictions in the diet.

Because leukemia and diabetes are so rarely found together, it was thought that some factor in the blood might be responsible. With this in view, the glycolytic rate of the blood was investigated. It is a well known fact that the blood sugar will gradually disappear when blood is allowed to stand in vitro. The reaction is influenced by the temperature of the blood. Cold retards it and heat hastens it, while it ceases if the blood is heated to 58 C. It occurs only in the presence of blood cells, especially of white blood cells.⁴ According to Schmitz and Glover⁵ the normal rate is from 15 to 23 mg. per hundred cubic centimeters of blood an hour. They reported that the glycolysis was more rapid in myelogenous leukemia, in which it may be 84 mg. The rate was parallel to the number of white blood cells, though they thought that the rate was dependent on the number of immature forms. They did not believe that the initial concentration of dextrose affected the rate of glycolysis in the normal or in the leukemic blood. Denis and Giles⁶

5. Schmitz, H. L., and Glover, E. C.: Glycolysis in Leukemic Blood, J. Biol. Chem. 74:761 (Sept.) 1927.

6. Denis, W., and Giles, U.: On Glycolysis in Diabetic and Non-diabetic Blood, J. Biol. Chem. 56:739 (July) 1923.

found glycolysis in normal blood much more active than in the blood of persons suffering from severe diabetes. Tolstoi⁷ disagreed with this, concluding that the two were the same when kept at a temperature of 37 C.

The rate of glycolysis in a specimen of whole blood which contained 600,000 white blood cells and many immature forms was determined for hourly periods up to the fourth hour. The specimen as taken showed 145 mg. of sugar per hundred cubic centimeters. At the end of the first, second, third and fourth hours it was 129, 120, 114 and 105 mg. respectively. This appears to be about normal.

The aforementioned data relate to the blood in vitro. It seemed possible that conditions in the blood during life might be different. We therefore investigated the blood sugar values of the last fifteen admissions of leukemia to the New York City Hospital for which there were records of fasting blood sugars. These showed a range from 80 to 174 mg. per hundred cubic centimeters. There was no difference between the myeloid and the lymphoid types.

The pancreas was examined in three of the earlier reported cases and no evidence of lymphatic infiltration was found. We were likewise unable to find any lymphatic infiltration in our case.

CONCLUSIONS

It would seem that the occurrence of diabetes and leukemia at the same time is very rare. The number of cases found is far below what would be expected from the rate of occurrence of these diseases individually.¹ In the majority diabetes precedes leukemia. The three types of leukemia are represented, though the lymphoid type is much the more common.

The rate of glycolysis was no different from that in normal blood. It could be said that the rate was unaffected by the excessive number of lymphoid cells or by the large amount of immature forms. Furthermore, it was shown that the blood sugar values in patients with leukemia without diabetes are within the normal range.

No explanation can be made, therefore, of this relationship between diabetes mellitus and leukemia from the evidence at hand.

THE DIAGNOSIS AND MANAGEMENT OF CHRONIC OBLITERATIVE VASCULAR DISEASE

CLINICAL LECTURE AT ST. LOUIS SESSION

LELAND S. MCKITTRICK, M.D.

BOSTON

During the ten year period from 1929 to 1939, 288 patients have been under the care of the members of the Peripheral Vascular Clinic at the Massachusetts General Hospital for the treatment of obliterative arterial disease due either to thrombo-angiitis obliterans or to peripheral arteriosclerosis. Between May 1923 and Jan. 1, 1939, 565 patients with arteriosclerotic gangrene associated with diabetes mellitus have been operated on by my associate Dr. Theodore C. Pratt and myself at the New England Deaconess Hospital. The disease of these patients was so advanced as to warrant their admission to the wards of either hospital. From a review of the records of these patients we shall try to summarize the problems in diagnosis and hospital treatment which this group presents.

SYMPTOMS AND SIGNS OF OBLITERATIVE ARTERIAL DISEASE

History.—The symptoms of progressive occlusion of the arterial supply to an extremity are similar regardless of the nature of the obliteration.

Intermittent claudication is one of the earliest and most common of these symptoms. It is variously described as a discomfort, lameness or at times a true cramp, which may be felt through the arches of the foot, in the calf of the leg or even in the muscles of the thigh or of the gluteal region. It is brought on by walking and is relieved by rest. Not infrequently the reference of discomfort to the arches of the foot is responsible for prolonged orthopedic treatment under the mistaken impression that the pain is due to faulty mechanics of the foot rather than to inadequate blood supply. This symptom may be a prominent part of the presenting complaint or it may be elicited only on careful questioning. Rest pain is usually a late symptom, though in patients suffering from thrombo-angiitis obliterans it is almost always present by the time hospitalization has become necessary. Paresthesias, such as coldness, numbness or burning, are often present. The burning at times may be so extreme that even the weight of a bed sheet cannot be tolerated. Some minor trauma or infection in a corn or around a nail is the usual precipitating factor which brings these patients to the hospital.

Physical Manifestations.—As a diagnosis sufficiently accurate for proper therapy can be made on a basis of careful clinical examination, no attempt will be made to discuss the more intricate procedures or mechanical means of evaluating the degree of vasospasm or of arterial obliteration.

The patient should be lying in bed or on a table. Both legs should be bared to the mid thigh and should be

Read in the Medical Division of the General Scientific Meetings at the Ninetieth Annual Session of the American Medical Association, St. Louis, May 16, 1939.

exposed to the room temperature for a period of from ten to fifteen minutes before the examination is carried out. To the experienced eye a comparison of the two extremities will give important information. The more normal the appearance of the foot, whether horizontal, elevated or dependent, the more normal is the arterial supply to that foot, whether it is through main arteries or through extensively developed collateral supply. A foot with deficient arterial supply is a foot deficient in oxygen and nutrition. Atrophy of the muscles and subcutaneous fat of the foot or calf, thin, brittle nails, a parchment-like skin or trophic changes at the tip of one or more digits are commonly noted. At times the foot and toes are a little swollen and full, though without actual pitting edema. On elevation, particularly if the foot is moved vigorously at the ankle, as suggested by Samuels,¹ blanching rapidly occurs; the veins in the foot collapse and it assumes a cadaveric hue. With the patient in a sitting position and the legs hanging over the edge of the bed, the gradual return of color is followed by the appearance of a marked rubor or cyanosis which may involve the toes alone but which may extend to, but rarely above, the junction of the upper and middle thirds of the lower part of the leg. The superficial veins fill slowly and then become tense and distended. Gross changes in skin temperature may be elicited with the examiner's hand. Beginning above the knees, different levels of the same leg and similar levels of the two legs are compared; a gradual or a sudden temperature change may be noted and this level will frequently coincide with that of color change.

Palpation of the dorsalis pedis, anterior tibial, posterior tibial, popliteal and femoral arteries to determine the presence or absence of pulsation is a most important part of the examination not only in relation to the diagnosis of obliterative disease but more particularly as a guide to treatment. The oscillometer is useful in confirming the presence or absence of pulsation in the main arterial channels or in eliciting a change in its character. It has not been of great help to us in interpreting the actual blood flow to the limb, especially through collateral vessels, and has been of little practical value in the actual management of these cases. The blood pressure cuff, inflated to slightly above diastolic pressure, serves as a practical method of comparing the oscillations at various levels of the same leg and at similar levels of the two legs.

Roentgenographic examination of the vessels to determine the presence or absence of calcification may be of value in differentiating between thrombo-angiitis obliterans and arteriosclerosis. It is however of no value in determining the adequacy of the lumen of the vessels and is therefore valueless as a factor in determining the level at which amputation, if necessary, should be done.

Spinal anesthesia, procaine block of one or more sensory nerves, and typhoid vaccine intravenously are used to determine the presence or absence of vasomotor spasm and are used rather to evaluate a possible ganglionectomy than as diagnostic procedures.

DIFFERENTIAL DIAGNOSIS

Thrombo-angiitis may be described as a generalized disease involving both arteries and veins. It is most frequently associated with pathologic changes of the peripheral vessels but may involve those of the mesen-

tery, heart, cerebrum and other viscera. The disease is usually chronic and, if untreated, progressive; but it may be of an acute fulminating type with symptoms of short duration and rapidly spreading gangrene necessitating early high amputation.² There is early diminution in or disappearance of pulsation in one or all of the peripheral arteries to the foot. Later the popliteal and not infrequently even the femoral artery may be obliterated. These patients have an extraordinary ability to develop a collateral circulation early, so that not infrequently one may see a patient with a useful foot entirely dependent on the collateral supply below the level of the groin.

Average age at onset.....	39 years	68.2 years	66.5 years

* This includes all diabetic patients admitted to the New England Deaconess Hospital from Jan. 1, 1935, through Dec. 31, 1938, with gangrene of either extremity, whether operation was required or not.

Thrombo-angiitis is a disease of the young and middle aged (table 1) and the symptoms are of years' rather than months' duration before the patient becomes urgently in need of treatment (table 2). It is not limited to any race and is rarely seen in a woman.³ The lower extremities are usually the first to be involved, one at a time, but only rarely is the disease limited to one foot. Involvement of the upper extremities is not uncommon but has occurred in only 24.2 per cent of the cases under consideration.

Migrating phlebitis occurring as small, tender, red, firm areas along the superficial veins of the extremities, not following the course of any one vein, is pathognomonic of the disease.

Calcification of the arteries demonstrable by x-ray examination may occur in thrombo-angiitis obliterans. It is usually slight in amount and is the exception rather than the rule (table 3). It has been present in 10 per cent of the twenty-nine cases in which roentgenograms have been taken and the diagnosis of thrombo-angiitis obliterans has been proved pathologically. In no case has the calcification been of more than slight degree.

A definite diagnosis of thrombo-angiitis obliterans would seem justified in a man 40 years of age or younger, with symptoms of years' rather than months' duration, without presence of calcification of his vessels on x-ray examination and with a normal content of blood sugar. A history of migrating phlebitis may or may not be present. A probable diagnosis may be made in a man between the ages of 40 and 55 with symptoms

2. This acute form of the disease has been present in two of our cases. One patient aged 24 years, who entered with a history of one month duration, had a bilateral thigh amputation within nineteen months of onset and died suddenly three years after onset. A patient aged 32 years, who nearly died following a mid thigh amputation three months after onset of symptoms, died at home two years after onset following ten days' illness, said to have been due to a gastric ulcer.

3. There is one questionable but no proved case of thrombo-angiitis obliterans in a woman in the records of the Massachusetts General Hospital.

1. Samuels, S. S.: The Early Diagnosis of Thrombo-Angiitis Obliterans, J. A. M. A. 92: 1571 (May 11) 1929.

of more than one year's duration who shows slight or no evidence of calcification by x-ray examination, particularly if there is evidence of involvement of an upper extremity. A diagnosis of thrombo-angiitis obliterans should rarely be made in a patient over 55 years of age, with or without demonstration of calcification of his vessels by x-ray examination and with a story of less than one year's duration at the time of his hospital admission. We should be unwilling to make a diagnosis of thrombo-angiitis obliterans in a woman unless she was 40 years of age or younger with a history of years' rather than of months' duration, without calcification on x-ray examination and with a normal blood sugar.

Arteriosclerotic gangrene is usually not difficult of diagnosis. It occurs at an older age (table 1), the symptoms are of months' rather than years' duration (table 2) and it affects both men and women, usually one leg at a time, but frequently it is or becomes bilateral. The upper extremity may be involved but rarely, only 7.4 per cent of 176 cases. Calcification is usually demonstrable by x-ray examination, although in 30 per cent of sixty-six proved cases such evidence was lacking. We believe that a diagnosis may be made with reasonable certainty in a patient 55 years of age or over with symptoms of less than one year's duration and with calcification of the vessels demonstrable by x-ray examination. As already described, it is impossible to make a positive diagnosis in a man between the ages of 40 and 55 with symptoms of approximately a year's duration and with little or no calcification on x-ray examination.

Arteriosclerotic gangrene associated with diabetes mellitus, while differing slightly from arteriosclerotic gangrene in nondiabetic patients, presents little in the way of a problem for diagnosis. It occurs in both men and women, is limited almost entirely to the lower extremities, and may appear at an early age (table 1). The symptoms are usually of short duration, but in many instances we have seen patients of whom a careful history has elicited symptoms of intermittent claudication years previously and the patient at the time of examination depended entirely upon collateral circula-

tion below the level of the femoral. Other patients, such as in senile gangrene, have a short progressive history. We have for years been looking for a patient with diabetes and thrombo-angiitis obliterans and as yet we have found no such case either among the patients at the Massachusetts General Hospital or in the large group of diabetic patients who have come under our care at the New England Deaconess Hospital. We therefore feel justified in making a diagnosis of so-called diabetic gangrene for any patient, male or female, with definite evidence of obliterative arterial disease associated with diabetes mellitus.

PRINCIPLES OF AND RESULTS AFTER TREATMENT

It is not within the limits of this discussion to go into the detail of or the reasons for the various therapeutic procedures used in the management of these cases. We can only refer to certain of the fundamental principles of treatment common to all forms of the disease, point out important variations in the response of the three different conditions already described and to the treatment available and emphasize the importance of carrying out certain procedures with a minimum of delay and with a maximum of care.

TABLE 3.—Calcification of Arteries of Legs by X-Ray Examination in Proved Cases (Massachusetts General Hospital)

	None	Slight	Definite
Thrombo-angiitis obliterans.....	89.7%	10.3%	0
Arteriosclerosis	30.3%	0	69.7%

All patients entering the hospital for treatment are given:

1. Bed rest. Sufficient medication is given to control pain. It is important that the resting position of the involved foot is such that the foot is not blanched (Buerger's 'angle of circulatory sufficiency'). Heat is avoided because of the inability of the circulation to respond to the increased demand for oxygen.
2. Careful hygiene. Careful examination of the feet is made for any evidence of epidermophytosis and if it is present active treatment is undertaken. In its absence or after it is controlled, the feet are massaged daily with hydrous wool fat. A small pillow is placed under the legs just above the heels so that there is no pressure to this vulnerable area. Handles are attached to a Balkan frame to facilitate movement in bed. In diabetic patients particularly, meticulous care must be given to the back.
3. General supportive measures such as iron for anemia, and a well balanced diet with adequate vitamin intake. Smoking is prohibited for patients with thrombo-angiitis obliterans, but only in isolated instances for patients whose process is due to arteriosclerosis with or without diabetes.
4. Buerger's postural exercises as modified by Allen,⁵ unless contraindicated by lymphangiitis or spreading infection.

5. Intermittent venous hyperemia⁶ based on the earlier work of Bier,⁷ later confirmed by Lewis and Grant,⁸ and recently introduced by Collens and Wilensky⁹ is a practical method for the treatment of peripheral vascular disease.

By careful attention to details and by learning to live within the circulatory possibilities of their feet, many patients in the earlier stages of obliterative disease may avoid or at least postpone the onset of gangrene for many years by the simple methods that have been enumerated. In the more advanced cases, however, these simpler methods will be unsuccessful and more active

procedures become indicated. The indications for and the response to treatment vary so markedly in the different conditions, they will be considered separately.

Thrombo-Angiitis Obliterans.—Every patient in this series with the diagnosis of thrombo-angiitis obliterans has had, at the time of admission, severe rest pain usually referred to the region of an open ulceration on one or more toes. To be successful, treatment must

TABLE 4.—Major and Minor Amputation in 112 Cases of Thrombo-Angiitis Obliterans (Massachusetts General Hospital)

Treatment	No. of Cases	Per Cent of Total	Mortality

Total	112	100.0	1.8 per cent

(1) relieve pain, (2) produce a maximum of vasodilatation, (3) increase collateral circulation and (4) so far as possible retard the progress of the disease.

Smoking.—This is prohibited. Samuels¹⁰ credits Michaels in 1909 with observing the effect of smoking. He and Silbert have for years stressed the important relationship between smoking and the disease, but not until Maddock and Coller¹¹ demonstrated the vasoconstriction associated with smoking was I convinced of the importance of complete cessation of smoking as fundamental in the proper treatment of this disease.

Nerve Block.—This was suggested by Silbert¹² in 1922 and popularized by Smithwick and White¹³ and is used extensively. It is, I believe, one of the most valuable procedures available in the care of the more advanced stages of the disease. Not only does it give complete relief from pain but there is associated a vasodilatation in the denervated area lasting from four to seven months. It has been used in 27 per cent of our cases.

Lumbar Ganglionectomy.—Excision of the second and third lumbar ganglions has been used more in recent years than formerly. Increasing experience has suggested that the vasomotor index is frequently so low as to suggest little benefit from this procedure. The maintenance of a dry foot with maximum vasodilatation affords optimal conditions under which a collateral circulation may be developed and maintained. I now feel that it is indicated for a good risk patient with a cold, moist foot which under spinal or peripheral block becomes dry and improves in color, even though the actual increase of temperature may be of no more than a few degrees.

Minor and Major Amputations.—The earlier and more effective the treatment, the fewer will be the number of patients subjected to major amputation. I cannot go into the indications for operation at this time. Faxon¹⁴ in his study of this same group of

patients, carefully considers this in his paper. It is, however, of extreme importance to realize that pain is no longer an indication for amputation in thrombo-angiitis obliterans and that septicemia is an extremely rare complication in this group. These patients are young, with their economic life ahead. Better a thorough trial at conservative treatment with minor amputation as indicated than a hasty decision for early amputation at a higher level without careful and thorough hospital treatment (table 4).

As frequent recurrences have been seen because of minor infections of a digit, we now do prophylactic amputations of the remaining toes of the affected foot in many of our cases after the patient's infection has been cleaned up and under the vasodilating influence of peripheral nerve block or sympathectomy.

Results.—It is our experience and that of Silbert, Samuels, Horton¹⁵ and others that early and proper treatment, particularly if this includes complete and permanent cessation of smoking, will in many instances be followed by a definite arrest of the obliterative process at least over a period of years. Late or inadequate early treatment, however, will result in a distressing morbidity. Between Jan. 1, 1929, and Jan. 1, 1939, 112 patients have been treated in the wards of the Massachusetts General Hospital for this disease. Although there has been progressive improvement in our understanding and management of the disease, the frightful economic burden of these patients and the distressing morbidity of the disease remain a challenge to our knowledge and care. The marked discrepancy between the results obtained by us and those obtained by Silbert and Samuels is most impressive. Table 4 shows that 25 per cent of our patients have left the hospital after an amputation of one or more toes and that 31 per cent of the group have required a major amputation. This is in striking contrast to the 6.4 per cent of Silbert's 687 cases and to Samuels' report of one major amputation in 300 patients seen over an eight year period. We offer no explanation for this discrepancy.

TABLE 5.—Major and Minor Amputation in 176 Cases of Arteriosclerosis (Massachusetts General Hospital)

Treatment	No. of Cases	Per Cent of Total	Mortality
No operation	43	24.4	7 per cent
Miscellaneous	11	6.25	0
Minor amputation only.....	11	6.25	0
Major amputation			
Single	96	54.6	16.7 per cent
Double	15	8.5	6.7 per cent
Total	176	100.0	11.4 per cent

any. Horton¹⁵ reports amputations in 22.5 per cent of his group of 948 cases observed over a thirty year period from 1907 to 1937.

Arteriosclerotic Gangrene.—Many of these patients enter the hospital because of severe pain preceding the actual onset of gangrene. In most instances careful adherence to the conservative regimen that has been described will permit adjustment of the patient's circulation to his oxygen needs, and many of these patients may be carried along for the remainder of their lives without the actual development of gangrene. When gangrene has actually developed so that all or a part of one or more toes is involved, the outlook is much more serious than in thrombo-angiitis obliterans. Nerve block

for the relief of pain is indicated only for the occasional patient with arteriosclerotic gangrene. Most patients who cannot be made pain free under three weeks of hospitalization as described will rarely have or develop circulation adequate to permit a satisfactory result following local amputation, and major amputation will usually be indicated. The element of vasospasm is not great and these patients are poor surgical risks, so that lumbar ganglionectomy has not seemed indicated. The

TABLE 6.—565 Operations for Diabetic Gangrene (New England Deaconess Hospital)

Treatment	No. of Cases	Per Cent of Total	Mortality
Minor amputation only.....	58	10.2	6 per cent
Miscellaneous	12	2.1	0
Major amputation

Total	565	99.9	12.9 per cent

tendency to develop adequate collateral circulation or circulation sufficient to permit the successful accomplishment of a local amputation for gangrene is very slight (table 5). It is our experience that in most instances a patient with arteriosclerotic gangrene becomes an economic burden to his family or to the community, and the ultimate result after the appearance of gangrene does not justify a prolonged period of hospitalization in the hope of avoiding a major amputation except in the occasional case.

Diabetic Gangrene.—Gangrene in a patient with diabetes mellitus is a medical and surgical emergency. Its successful management requires the most meticulous attention to detail, early operation when and where indicated and carefully performed, plus complete cooperation with and from the medical components of the team. The mortality associated with amputation for gangrene is appalling. That excessive mortalities are unjustifiable and are the result of delayed or inadequate treatment, there can be no doubt. The average diabetic patient with gangrene is about 66 years old, he has had diabetes for eight years, and he has advanced arteriosclerosis. He has, in addition, a metabolic disease more difficult of control in the presence of infection and a lowered resistance to local and general infection. Between 5 and 6 per cent of the patients treated for gangrene without operation at the Deaconess Hospital have died of cardiovascular-renal disease. With a mortality of 10.5 per cent for all operations on the lower extremities of 883 diabetic patients at this same hospital, about one half of these, or 4.6 per cent of the entire group, have died of degenerative processes. With but few exceptions the difference between this mortality of approximately 5 per cent and our actual mortality is the mortality of delayed or inadequate treatment. This delay may be your responsibility as a practitioner, yours as an internist, or mine as a surgeon. It may be, and probably frequently is, that of the patient. Nevertheless it is a responsibility which you and I must accept and do all in our power to justify.

Approximately half of these patients admitted to the New England Deaconess Hospital are successfully treated without operation. Once gangrene has definitely developed so as to involve all or a part of the deeper structure of one or more toes of a pulseless foot, the chance of extending infection and possible death is greater than the chance of spontaneous amputation and

permanent healing. Early decision of the level for amputation should be followed by an early and carefully executed operation. We have been able to do a successful removal of a gangrenous toe in only 10 per cent of our patients. When amputation at a higher level is necessary, that procedure assuring the greatest safety and shortest period of hospitalization is usually indicated. We therefore prefer amputation through the femur just above the condyles for most of these patients whose condition will permit primary closure.¹⁶ For bad infections in patients badly depleted from long standing sepsis and untreated diabetes; in short, for any case in which in our judgment primary closure is unsafe, we employ a guillotine amputation usually through the lower leg. This has been necessary in only 6 per cent of our cases. In carefully selected cases, closed amputation through the lower leg or a Gritti-Stokes type of operation is done. We feel strongly, however, that either a lower leg or Gritti-Stokes amputation is justified only when the patient's general condition is sufficiently good to permit subsequent use of an artificial limb.

CONCLUSIONS

A review of the records of 112 patients with thromboangiitis obliterans and 176 patients with arteriosclerotic gangrene under the care of the Peripheral Vascular Clinic at the Massachusetts General Hospital, and 565 patients with diabetic gangrene under my care at the New England Deaconess Hospital suggest that:

1. Thrombo-angiitis obliterans is a disease of young and middle-aged men with symptoms of years' duration.
2. It is rarely seen in a woman.
3. Calcium deposits in arteries are only rarely demonstrated by x-ray examination and when present are slight in amount.
4. Certain cases in men between the ages of 40 and 55 may be indistinguishable clinically from cases of gangrene due to arteriosclerosis.
5. In spite of improvements in management of these cases, 30 per cent of our cases have come to major amputation.
6. Twenty per cent of sixty-six proved cases of arteriosclerotic gangrene failed to show calcium deposits in the arteries of the legs by x-ray examination.
7. Sixty-three per cent of 176 patients treated with a diagnosis of arteriosclerotic gangrene came to amputation through or above the lower part of the leg.
8. Early and adequate treatment of diabetic gangrene is of great importance.

205 Beacon Street.

16. Fifty-three per cent of 559 patients operated on by us for gangrene prior to Jan. 1, 1939, had primary closed thigh amputations with a mortality of 11.7 per cent (McKittrick, L. S.: *Am. J. Surg.* 44: 46 [April] 1939).

Classification of Mental Diseases.—Three general diagnostic categories of mental disease are recognized: the organic psychoses, the functional psychoses and the psychoneuroses. The principal organic psychoses are senile dementia, cerebral arteriosclerosis, general paresis and the alcoholic psychoses. In these disorders there exists a known physical or organic basis. The principal functional psychoses are dementia praecox, manic-depressive psychosis, involutional melancholia and paranoia. To date, no demonstrable organic pathology has been shown in these psychoses, so that hereditary and constitutional factors are considered to be of chief etiological importance. The etiological factors in the psychoneuroses and in the psychoses allied with psychopathic personality are usually said to be psychogenic.—Landis, Carney, and Page, James D.: *Modern Society and Mental Disease*, New York, Farrar & Rinehart, Inc., 1938.

Council on Physical Therapy

THE COUNCIL ON PHYSICAL THERAPY HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORTS.

HOWARD A. CARTER, Secretary.

LIEBEL-FLARSHEIM SW-221 SHORT WAVE GENERATOR ACCEPTABLE

Manufacturer: The Liebel-Flarsheim Company, 303 West Third Street, Cincinnati.

The Liebel-Flarsheim SW-221 Short Wave Generator is recommended for medical and minor surgical diathermy. It is furnished in an all metal semiportable cabinet with a separate subcabinet. Standard equipment includes inductance cable, cuff and pad electrodes and a treatment drum on a counterbalanced, adjustable arm. Various surgical accessories for coagulation and desiccation are also available. The shipping weight for the entire unit is about 175 pounds. Without subcabinet and accessories, the shipping weight is 98 pounds.

Liebel-Flarsheim
SW-221 Short Wave
Generator.

A tuned plate, tuned grid oscillating circuit is utilized, with the patient's circuit inductively coupled to the oscillator. There is a variable condenser in the patient circuit for resonating this circuit with the oscillator. A single tube is employed, operating at a wavelength of approximately 16 meters. The input power required to operate the unit at full load is 750 watts, according to the firm, and the output, using a

lamp load, is 260 watts. The final temperature of the transformer after a run of two hours at a full load came within the limits of safety.

A filter is employed in the supply line for the purpose of minimizing line feed-back for possible radio interference. The circuit also incorporates a device which protects the oscillator tube from overload and gives an audible signal when the unit needs readjustment.

Tests were submitted by the firm to support claims made for the heating efficacy of the unit when applied to the human thigh.

Averages for Six Tests with Each of Three Technics

Technic	Deep Muscle, Degrees F.		Oral, Degrees F.	
	Initial	Final	Initial	Final
Coil	96.3	105.8	97.6	98.2
Cuff	97.3	104.6	97.9	98.1
Treatment drum	96.9	103.6	97.8	98.5

In addition, the firm submitted evidence to support the use of this unit in producing hyperpyrexia and for orificial heating. Seven fever therapy charts were supplied indicating tempera-

Schematic diagram of circuit.

ture and pulse readings at fifteen minute intervals. These were run with the SW-221 Short Wave Unit and the Liebel-Flarsheim Fever Cabinet. Analysis of six charts shows that an average temperature of 106 F. or over was reached in an average induction period of approximately one and two thirds hours (unit on-off). From these data it would appear that the

SW-221 Short Wave Unit may be used for raising general body temperature to 106 F. or over when used with the Liebel-Flarsheim Fever Cabinet for maintaining the temperature at the desired level.

Seventeen tests were made with the SW-221 Short Wave Unit and the Chapman vaginal electrode. Twelve of these were carried out in an office of a qualified physician and five of them at a clinic. The twelve show an average initial temperature of 98.7 F. and an average final temperature of 108.6 F. Of the five tests, the initial average temperature was 97.8 F. and the average final reading was 108.4 F. These figures indicate that this unit may be efficacious for pelvic heating.

The unit was investigated in a clinic acceptable to the Council and it was reported to give satisfactory service.

In view of the foregoing report, the Council on Physical Therapy voted to accept the Liebel-Flarsheim SW-221 Short Wave Generator for inclusion in its list of accepted devices.

WESTINGHOUSE THIN WINDOW LAMP ACCEPTABLE

Manufacturer: Westinghouse X-Ray Company, Inc., Long Island City, N. Y.

The Westinghouse Thin Window Lamp provides mercury arc radiation of an essentially monochromatic wavelength of 2,537 angstroms for limited use by the physician as a bactericidal and fungicidal agent. There is also thermal radiation from a hot cathode. The unit is compact, consisting of a Thin Window Lamp, shield and transformer, all of which are demountable from the stand for portable use. The arm holding the lamp housing on the stand is adjustable in various directions. Ultraviolet radiation is emitted only through a narrow treatment port in the hood, which also provides ventilation to the lamp. The hood and rim of the treatment port can be sterilized. Goggles and a velvet-lined carrying case are also provided.

Westinghouse Thin
Window Lamp.

The high vacuum, hot cathode, mercury vapor glow lamp is encased in an envelop of high transmission glass with a very thin window (approximately $\frac{1}{1,000}$ inch). The high emission filament is flanked by two anodes. The transformer and lamp require about 50 watts to function at 110 volts alternating current.

In order to operate the lamp, the rated voltage is applied to the filament for fifteen seconds for preheating purposes, after which the plate voltage is applied to each anode by a thermostatic relay. The arc is formed in mercury vapor present in the lamp and the radiations emanating are characteristic of a mercury arc discharge. The power supply is connected to the lamp through a specially designed transformer the inherent regulation of which automatically adjusts the current supplied to the lamp. A spectrum of the lamp radiation was submitted.

The radiometric investigation by the Council revealed ultraviolet 55 per cent, visible 10 per cent, infra-red 35 per cent.

1. *Spectral Radiation Intensities.*—The spectral ultraviolet intensities were determined radiometrically with a vacuum thermopile connected with an achromatic quartz-fluorite spectrometer and corrected for absorption. The spectral energy distribution differs remarkably from that of the low voltage, "hot quartz," mercury vapor lamp, having one or both electrodes of mercury, in which the intensity of the resonance emission line at 2,537 angstroms depends on the temperature and hence the amount (absorption) of mercury vapor in the burner. In the present model all the mercury is vaporized, there is no marked absorption by cool mercury vapor, and the intensity of the emission line at 2,537 angstroms, relative to the emission lines at longer wavelengths, is about three times that of this same line emitted by a so-called hot quartz lamp.

The intensity of the emission lines at 2,967, 3,024 and 3,132 angstroms respectively is somewhat higher than that of the high potential mercury vapor lamp.

Of the biologically effective radiation, including 3,132 angstroms and shorter wavelengths, over 80 per cent is in the emission line at 2,537 angstroms, recognized as having a strong germicidal action.

2. *Total Radiation Measurements.*—The intensity of the ultraviolet emitted by the lamp was determined by means of a differential thermopile and filter radiometer, recommended by the International Committee on Measurement and Standardization of Ultraviolet for Use in Medicine.

At a distance of 35 mm. from the front edge (portal protector) of the lamp housing, the intensity of the ultraviolet radiation, including 3,132 angstroms and shorter wavelengths, was found to be 650 microwatts per square centimeter. Of this amount, over 500 microwatts per square centimeter is in the highly germicidal emission line at 2,537 angstroms. Owing to absorption by the glass window and by the air, the intensities of the emission lines at 1,849 and 1,950 angstroms respectively are relatively weak radiometrically.

The erythemalogenic efficiency of the emission line at 2,537 angstroms being only about 55 per cent that of the maximum at 2,967 angstroms, it is possible to deliver about twice as much radiation without causing an erythema. Moreover, in comparison with the skin tolerance to wavelengths at 3,134 angstroms, the biologic effects are distinctive in that a large overexposure is permissible without causing a blister.

Under radiometrically controlled conditions a threshold erythema (minimum perceptible erythema) was produced on the untanned skin by an exposure of sixty seconds at a distance of 35 mm. in front of the portal protector of the lamp, in good agreement with the calculated time of exposure of seventy seconds.

As evidence to establish the bactericidal and dermatologic effects of the lamp, the firm furnished reports of clinical and experimental studies from various physicians. A study of the *in vitro* bactericidal effects of the lamp was also furnished.

Five qualified physicians investigated the lamp for the Council. Clinical tests on normal skin revealed that even prolonged exposures (fifteen minutes) with the Thin Window Lamp failed to produce vesiculation. Persistent erythema, followed by exfoliation, was noted in all cases in which the prolonged exposures were given. Of the many dermatologic conditions that were treated with varying doses, none showed any irritation.

The lamp was used successfully for the treatment of furuncles, carbuncles, chronic granulating surfaces and various localized skin diseases. It is not to be assumed, however, that the lamp may be substituted for x-rays, other forms of ultraviolet generators or conventional topical remedies for the treatment of many dermatologic conditions.

The lamp was recommended after these studies for the reasons that:

1. It emits ultraviolet radiations and is a generator of essentially monochromatic ultraviolet radiation of a wavelength which produces persistent erythema without blistering, combined with infra-red radiation.
2. It is bactericidal *in vitro*.
3. It is particularly suitable for treating small lesions and diseases of the skin of limited localization. The claim that the Thin Window Lamp is a useful aid in controlling pyogenic, fungous and parasitic skin infections, indolent ulcers and wounds cannot be wholly substantiated according to some clinical experience. There is no doubt that *in vitro*, pyogenic and fungous organisms may be attenuated or destroyed, but *in vivo* the beneficial effects of ultraviolet radiation emitted by the Thin Window Lamp on disease caused by these organisms are not so striking.
4. It is easy and convenient to use.
5. It is portable.
6. It has a good margin of safety in its application. In view of the foregoing report, the referee recommends that the Council on Physical Therapy accept the Westinghouse Thin Window Lamp for inclusion in its list of acceptable devices.

Council on Pharmacy and Chemistry

NEW AND NONOFFICIAL REMEDIES

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION.

PAUL NICHOLAS LEECH, Secretary.

SULFANILAMIDE (See New and Nonofficial Remedies, 1939, p. 463).

Sulfanilamide-Merrell.—A brand of sulfanilamide-N. N. R. Manufactured by the Wm. S. Merrell Company. No U. S. patent or trademark.

Sulfanilamide Tablets, 5 grains.
Sulfanilamide Tablets, 7½ grains.

SULFANILAMIDE-ABBOTT (See New and Nonofficial Remedies, 1939, p. 466).

The following dosage form has been accepted:
Sulfanilamide-Abbott, 4 Gm. Ampoules (Crystals).

IMMUNE GLOBULIN (HUMAN) (See New and Nonofficial Remedies, 1939, p. 412).

Sharp & Dohme, Inc., Philadelphia and Baltimore.
Immune Globulin (Human).—A sterile concentrated globulin obtained from human placental blood and tissue and containing immune factor or factors against measles. The placentas are repeatedly incised and extracted with 4 per cent saline solution for forty-eight hours. The soluble material is centrifuged, precipitated with ammonium sulfate, filtered, and otherwise refined and concentrated by standard methods used in the concentration of antitoxins. The final product is adjusted to a pH of 7.0 and contains 0.5 per cent of phenol. Sterility is obtained by filtration. Its immunizing potency is determined on the basis of the diphtheria antitoxin titer of the placental blood. Marketed in packages of 2 cc. and 10 cc. ampule-vials.

STEARNS VIOSTEROL (A. R. P. I. PROCESS) IN OIL.—A brand of viosterol in oil-N. N. R.

Manufactured by the American Research Products, Inc., a subsidiary of General Mills, Inc., Minneapolis, under license agreement with E. I. du Pont de Nemours Company (Frederick Stearns & Company, distributor). U. S. patent 2,117,100 (May 10, 1938; expires 1955).
Stearns viosterol (A. R. P. I. Process) in oil is prepared by the activation of ergosterol by low velocity electrons. The activated ergosterol is refined and dissolved in vegetable oil. The final product is biologically assayed to contain not less than 10,000 units (U. S. P.) of vitamin D per gram.

STEARNS COD LIVER OIL CONCENTRATE IN VEGETABLE OIL.—A concentrate of the nonsaponifiable fraction of cod liver oil dissolved in corn oil, adjusted to a potency of not less than 58,800 units (U. S. P.) of vitamin A per gram and not less than 5,800 units (U. S. P.) of vitamin D per gram.

Actions and Uses.—It possesses the therapeutic properties recognized for the vitamins present in cod liver oil.
Dosage.—For the liquid: Daily prophylactic dose for the average infant and child, from 6 to 9 drops. For the capsules: One capsule daily.
Manufactured by the International Vitamin Corporation, New York (Frederick Stearns & Company, Detroit, distributor). The concentrate used is made under U. S. patent 1,690,091 (Oct. 30, 1928; expires 1945).
Stearns Cod Liver Oil Concentrate Capsules, 3 minims.—Each capsule contains 3 minims of Stearns cod liver oil concentrate in vegetable oil adjusted to a potency of not less than 10,000 units (U. S. P.) of vitamin A and 1,000 units (U. S. P.) of vitamin D per capsule.

STEARNS COD LIVER OIL VITAMIN CONCENTRATE TABLETS.—A concentrate of the nonsaponifiable fraction of cod liver oil in the form of tablets, each having a potency of not less than 3,150 units (U. S. P.) of vitamin A and 315 units (U. S. P.) of vitamin D.

Actions and Uses.—Stearns cod liver oil vitamin concentrate tablets possess properties similar to those of cod liver oil so far as these depend on the vitamin content of the latter.
Dosage.—Two to three tablets daily, or as prescribed by physician.
Manufactured by the International Vitamin Corporation, New York (Frederick Stearns & Company, Detroit, distributor). The concentrate used is made under U. S. patent 1,690,091 (Oct. 30, 1928; expires 1945).

STEARNS HALIBUT LIVER OIL PLAIN.—A brand of halibut liver oil-N. N. R.

Prepared by the International Vitamin Corporation, New York (Frederick Stearns & Company, Detroit, distributor). No U. S. patent or trademark.
Stearns Halibut Liver Oil Plain, Capsules, 3 minims.—The content of each capsule is assayed to contain not less than 10,000 units (U. S. P.) of vitamin A and not less than 170 units (U. S. P.) of vitamin D.
Stearns halibut liver oil plain is prepared by extracting the oil of fresh halibut livers. The oils are refined and assayed biologically to have not less than 59,000 units (U. S. P.) of vitamin A and 1,000 units (U. S. P.) of vitamin D per gram.

EPIDEMICS AFTER WARS

In practically every war for which accurate records are available, disease has always caused more deaths than military maneuvers and engagements. Typhus, plague, cholera, typhoid, dysentery, pneumonia and influenza do more damage under military conditions than can be brought about by dynamite, torpedoes, gun powder and poison gas. As Dr. Hans Zinsser has said, "Epidemics get the blame for defeat; generals the credit for victory. It ought to be the other way around."

In many a great war of the past, epidemic has come to terminate the conflict. According to Lieut. Col. Nelson Mercer,¹ the Persians under Xerxes were defeated in their invasion of Greece by plague and dysentery. In 1741 the French captured Prague because of a typhus epidemic among the Austrian defenders. Napoleon's campaign failed in Russia because of typhoid, typhus and pneumonia. In the Mexican War of 1846-1847, 100,000 soldiers went to Mexico; of these 10,986 died of typhoid, dysentery, smallpox, malaria and tropical diseases—only 1,549 were killed or died of wounds. In the Civil War the Union Army lost more than 200,000 men by disease and approximately 112,000 from battle wounds.

The records of the Spanish-American War and of the World War are so recent that they linger in the memories of many of us. In the Spanish-American War deaths of American troops in battle were 379, but 4,795 died from disease, most of them never reaching Cuba. In the camps in this country typhoid caused 20,904 cases and 2,188 deaths. During the World War, Mercer points out, our losses were 58,119 from disease, 50,385 killed or died of battle wounds. A large percentage of deaths were, of course, the result of the pandemic of influenza which prevailed in 1918. By this time typhoid had been brought under control so that there were only 2,200 cases of typhoid among more than 4,000,000 soldiers, and there were only 200 deaths.

When influenza swept the world in 1918, epidemiologists undertook investigations and surveys with a

view to developing knowledge which might prevent a similar occurrence in the future. At that time it became evident that there is a periodicity in these attacks and that it might reasonably be suspected that a similar epidemic would return twenty-five or thirty years later. Recently Dr. Thomas M. Rivers of the Rockefeller Institute told the Congress on Microbiology in New York that another outbreak of influenza may well be expected in association with the present war. He pointed out at the same time that we have not as yet any effective weapon for either the prevention or the treatment of influenza.

In the World War of 1918 the problems of tetanus and of gas gangrene were serious. Much was learned relative to the proper treatment of war wounds. Since that time there has been great advance in the development of antiseptics and of the surgery of trauma. New drugs like sulfanilamide and sulfapyridine give possibility of control over various types of infection which formerly were invariably fatal. Pneumonia of certain forms has begun to yield to specific antisera and to sulfapyridine. Gas gangrene, too, seems to be more amenable to modern chemotherapy, whereas it was apparently resistant to all efforts in 1918. In the last world war, trench fever and trench mouth accounted for vast numbers of cases of disability. We have learned much, too, about the control of these conditions.

Yet the fact remains that the assembling of great masses of men under conditions in which sanitation is difficult, if not impossible, and the movement of great numbers of men across wide areas of country where they come in contact with new populations invariably mean the spread of disease. The louse that spreads typhus fever, the rats concerned with plague, and many another insect and animal carrier of disease still exist, ready to demonstrate, when the favorable opportunity comes, that man is but a morsel in the great cosmic scheme and that when he seeks to destroy himself nature stands cynically ready to assist him.

GROUP HEALTH ASSOCIATION CONTRACT UNIQUE BUT NOT INSURANCE, SAYS U. S. COURT

In the opinion of the United States Court of Appeals for the District of Columbia,¹ the contract between Group Health Association, Inc., and its members may be unique, the obligation assumed by the corporation to its membership may be tenuous and the members' responsibility to it may be correlatively attenuated, but the contract is not one of insurance or indemnity. The court, in a decision rendered September 11, thus upheld the judgment of the District Court of the United States for the District of Columbia, that Group Health Association does not have to comply with the insurance laws of the District of Columbia. Whether or not the contract is a fair one, or whether or not it lacks sufficient

1. Mercer, Nelson: *Disease in Military Campaigns*, Mil. Surgeon 78: 130 (Feb.) 1936.

1. Albert F. Jordan, Superintendent of Insurance for the District of Columbia, appellant, v. Group Health Association, a corporation, appellee, decided Sept. 11, 1939.

consideration or mutuality of obligation to be valid and enforceable, the court refrained from discussing; those issues were not before it. A contract of insurance, the court pointed out, is predicated on the existence of a risk of loss to which one party may be subjected by contingent or future events and an assumption of that risk by another, by legally binding arrangement. Hazard is essential, and equally so a shifting of the resulting liability from the person primarily exposed to risk to some one else. If there is no risk, or there being one it is not shifted to another or others, there can be, in the judgment of the court, neither insurance nor indemnity. After reviewing the by-laws of the corporation, not as they were originally adopted in 1937 but as they have been variously amended since that time, the court was convinced that neither of these two elements was present in the contract entered into between the corporation and its members. The effect of the Group Health Association arrangement, according to the by-laws as interpreted by the court, is to make available to members, if they wish to receive them, the services of the physicians employed by the corporation. The only obligation the corporation assumes toward its members is to make contracts with physicians and others. There is no agreement or binding obligation to provide such service or see that it is supplied. It does not guarantee that any of the services will be rendered nor does it assume any liability for any act of omission or commission by any physician who does render them. If for any reason it becomes unable to procure any or all such services when called on to do so, its only obligation is "to use its best efforts to procure the needed services from another source." After carefully reviewing the by-laws of the corporation, the court referred to the obligation assumed by the corporation as tenuous and to the contract as unique. The court called attention to the uncertainty of the member's right of recourse against the corporation for a breach of its contract with him to emphasize the non-existence of an assumption of risk by the corporation or an agreement of indemnity.

Even though Group Health Association, Inc., were otherwise within the purview of the insurance laws, the court thought that the corporation was a "relief association not conducted for profit composed . . . solely of employees of any other branch of the United States government service," within the meaning of the insurance laws of the District of Columbia and thus excused from complying with such laws. The court did not refer, however, to any provision in the by-laws of the corporation that limits the services of physicians employed by it to members who in fact need financial aid. So far as is known there is no such limitation, the member who is a charwoman and the member who is a highly paid executive being entitled to the same quality and quantity of services. Although the insurance laws provide that a relief organization must be composed solely of employees of the government to be

entitled to exemption, the court thought that the fact that dependents of employees are entitled to membership in the corporation does not disturb its exempt status. The court based its construction of the law in this respect only on what it referred to as "the almost universal practice of relief associations and departments" and not on any statute or court decision.

The gist of the decision seems to be that the contract between Group Health Association, Inc., and its members imposes no legally enforceable obligation on the corporation to furnish relief or service of any kind under any condition and that, since the corporation assumes no risk to which a member may be subject, the contract is not one of insurance and the corporation is not engaged in the business of insurance.

HEALTH INSURANCE IN AUSTRALIA
AND NEW ZEALAND

At a time when there seems to be much controversy as to the exact status of health insurance and legislation for state medicine in Australia and New Zealand, the official report of the Committee on Economics of the Canadian Medical Association,¹ presented at the annual meeting in Montreal, June 19 to 23, is especially welcome. The similarity of reactions of the medical profession throughout the world indicates how much physicians are concerned everywhere in maintaining suitable standards of medical practice.

In 1924 the commonwealth government of Australia appointed a royal commission on national health insurance. This commission omitted medical benefits from its system of insurance and recommended only old age pension and sickness benefit. Action did not follow this report. Then in 1935 the commonwealth government invited Sir Walter Kinnear, controller of the insurance department, Ministry of Health, England, to visit Australia and to assist in the investigation of a national health insurance scheme. Sir Walter did not consult with the medical profession while on this visit, but when he was again called in 1938, representatives of the profession did meet with him and discuss the problem. A bill, however, was prepared without consideration of the position of the medical profession. The main objections of the physicians to this bill were (1) the control of medical benefits by lay persons, (2) the power of the insurance commission with regard to regulations (i. e. bureaucratic control) and (3) the inadequate payment. Despite the protests of the profession, the bill was forced through both houses in April 1938.

Objections from the people of Australia supplemented those of the medical profession as the provisions of the bill became known. It was discovered that the unemployed and the unemployable and their dependents were not insured and that, while there was a wage limit of £365 per annum, there was no total income limit. For these and other reasons the medical profession opposed

1. *Canad. M. A. J.* 41:47 (Sept.) 1939.

the act and substituted a proposal of its own which provided for a definite income limit, representation of the medical profession in the administration, free choice of doctor and a definite scale of fees.

Early in 1939 the federal government decided to abandon completely its national insurance scheme. This was partly because of the "fear that the financial burden involved might stifle normal developmental expenditure if it fell simultaneously with the heavy defense program" and while the greater part of the commonwealth is suffering from the effects of severe drought and widespread bush-fires; and secondly, because the act is highly unpopular throughout Australia, and its introduction against the wishes of the people might lead to grave political consequences."

New Zealand already had an extensive public health service, giving the department of health wide powers. Then in 1938 the Social Security Act was passed to become operative April 1, 1939. This act, along with benefits for superannuation, invalids, widows, orphans, families with more than two children, minors and the unemployed, and cash benefits during sickness, provided for general practitioner service to all residents of New Zealand regardless of income. This also included the supply of all necessary drugs and medicines, appliances, free treatment in public hospitals, partial payment of private hospital charges, clinical and other outpatient services, free treatment in state mental hospitals and in public maternity hospitals, the services of doctors, nurses and all other necessary services in maternity cases, and also home nursing and domestic assistance, services of specialists and consultants, radiologic and laboratory services, and dental and ambulance services.

This law was preceded by an investigation by a committee of seven members of the house of representatives with a socialist doctor as the chairman. When the bill was introduced in accordance with these recommendations, the medical profession with a unanimity of 95 per cent resolved to oppose the measure. The bill, nevertheless, was rushed through parliament with a vote of fifty-six out of eighty seats.

About a month after the bill was passed, a general election was held at which the government increased its majority. This vote was accepted as a popular endorsement of the social security act. As opposition grew the government made overtures to reopen discussion, proposing to introduce a system of remuneration on a basis of payment for service rendered. There does not appear, however, to be much possibility of closer accord between the government and the medical profession. There does not seem to be any great popular demand for health insurance. The physicians of New Zealand hold that on account of existing facilities there is less need for a system of health insurance in New Zealand than anywhere else in the world. The medical profession has indicated its willingness to cooperate with the government on all matters affecting the health of the community, but little advantage has been taken of

this offer. The act provides for a levy on all earnings of the community in the form of a social security tax of 1 shilling in the pound. The medical profession addressed a letter to the committee of the House of Representatives on National Superannuation and Health Insurance, which said among other things:

All are agreed that the promotion of health is a greater object than the treatment of sickness in that prevention is better than cure. We do not underestimate the importance of curative medicine, but national health insurance, which is really a system of indemnification for sickness, does not (especially in the proposals put forward by the government) materially advance the greater object of the promotion of health. There are certain conditions in relation to environment, to conditions at work, to domestic help, to nutrition of the young, to preventive medicine and to research which we as a profession know to be unsatisfactory. . . . Continuous and studied attention to those conditions will do far more for the people than the introduction of any costly system of health insurance, and the provision of a universal general practitioner service would do nothing toward remedying these deficiencies.

Current Comment

THE STUDENT SECTION

In this issue on page 1267 the Student Section of THE JOURNAL begins its second year. The leading article on factors influencing ethical concepts and ideals among medical students is contributed by two students of Emory University School of Medicine, Atlanta, both officers in the American Association of Medical Students. This paper is followed by an address by the president of the Royal College of Surgeons of England before a graduating class of medical students; also a discussion of the question "Should Students Marry?" and a summary of the accomplishment of freshmen in eighty-five medical colleges in the United States and Canada. These articles and the news items on succeeding pages should help medical students adjust themselves to their work. The Student Section is devoted to the educational interests and welfare of medical students, interns and residents in hospitals. Any one interested may submit papers, correspondence or news items, which will be given careful consideration.

MICHAEL M. DAVIS AND THE COMMITTEE OF PHYSICIANS

In the current issue of *Survey*—the midmonthly for September 1939—appears an article entitled "Senators, Doctors and National Health," by Michael M. Davis, chairman of the Committee on Research in Medical Economics, Inc. The Committee on Research in Medical Economics, Inc., readers will remember, is conducted with a matter of \$135,000 donated by the Rosenwald Foundation as its final contribution in the medical economics field. Mr. Michael M. Davis is, for five years, to undertake studies in the field of medical economics, where his interests and his invitations lead him. His article, which occupies one page of the *Survey*, is apparently a review of the preliminary report of the subcommittee of the Senate Committee on Education and Labor. Mr. Davis presumably speaks strongly for the so-called Committee of Physicians and bitterly if

not sneeringly about the American Medical Association. He urges popular groups to realize that the physicians of this committee will work with them toward a common goal. The Committee of Physicians has not made public for some time any information concerning its official personnel, its financial status, the methods by which its conclusions are reached or the extent to which the original signers, that is the 430, or the subsequent signers, participate either in drawing up or approving its conclusions. Such information would undoubtedly be of value to the medical profession in its evaluation of the significance of the actions taken and the propaganda circulated by this body. By most physicians the testimonial of Mr. Michael M. Davis will not be considered an endorsement.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

ARIZONA

Study of Trachomatous Navajo Children.—From June 1 to July 17 medical officials of the Indian Medical Service made a study of trachoma in 122 children from the Navajo Indian Reservation. The children were brought from day schools on the reservation to the boarding school at Fort Defiance and received courses of sulfanilamide treatment covering a period of twenty-two days. The laboratory work was done at the Navajo General Hospital, Fort Defiance.

ARKANSAS

Changes in Health Officers.—Dr. Leroy L. Fatherree has been appointed full time health officer of Little Rock to succeed the late Dr. Thomas M. Fly.—Dr. John T. Herron, Little Rock, has been assigned as health director of the district composed of Ashley, Desha and Chicot counties.

State Medical Board Elects.—Dr. Lorenzo T. Evans, Batesville, has been elected president of the State Medical Board of the Arkansas Medical Society; Dr. De Veaux L. Owens, Harrison, vice president, and Dr. Daphney E. White, El Dorado, secretary.

Trachoma Investigation.—The state board of health in cooperation with the state department of public welfare began a study of trachoma in Arkansas with a diagnostic clinic in Jonesboro August 24. This was said to be the first clinic of its kind in the state and was extended to the population of the northeastern part of the state, where trachoma appears to be prevalent. Drs. Arthur M. Washburn, director of the division of communicable disease of the state board of health, and Kingsley W. Cosgrove, state supervising ophthalmologist for the welfare department, were in charge of the clinic. They were assisted by Drs. William B. Harrell Jr., Jonesboro, county health officer, Martin E. Blanton and Oscar T. Cohen, Jonesboro, district ophthalmologists for the welfare department. A study of trachoma in relation to blindness by this group during the past year shows that about 90 per cent of the blind examined have suffered from trachoma.

CALIFORNIA

Epilepsy a Reportable Disease.—Epilepsy is now a reportable disease in California, according to the state department of health. The new law went into effect September 19. In the future it will be the duty of every practicing physician to report every patient with epilepsy to the local health officer, who will send the report to the state department of public health. This information will then be made available to the motor vehicle department. Failure to report will constitute a misdemeanor.

COLORADO

State Medical Meeting in Colorado Springs.—The sixty-ninth annual session of the Colorado State Medical Society will be held at the Antlers Hotel, Colorado Springs, October 5-7, under the presidency of Dr. Leo W. Bortree, Colorado Springs. The guest speakers will include:

Dr. Knox E. Miller, Washington, D. C., Role of the Medical Profession in the Control of False and Misleading Advertising.
Miss Joy Erwin, Denver, The Doctor and the Nurse at Work.
Dr. Rock Sleyster, Wauwatosa, Wis., President, American Medical Association, Medical Problems of the Day.
Dr. Neely C. Washburn, Randolph Field, Texas, Physical, Physiologic and Psychologic Considerations in Selecting Personnel for Military Aviation.
William S. McNary, Denver, The Doctor's Stake in Group Hospitalization.
Dr. Irving S. Cutter, Chicago, The Significance of Minor Signs of Indigestion.
Dr. Harry R. Foerster, Milwaukee, Occupational Dermatoses.
Donald E. Cummings, Saranac Lake, N. Y., Tuberculosis in Industry.
Dr. Royd R. Sayers, Washington, D. C., Industrial Hygiene.

Advertising claims versus medical facts will be discussed in a symposium from the University of Colorado School of Medicine, Denver, covering blood tonics, cathartics, sedatives, cosmetics and tobacco; the speakers will be Drs. William A. Rettberg, Ora L. Huddleston, Charles A. Rymer, Gerald M. Frumess and Robert T. Terry. Dr. Miller's paper will be an adjunct to the symposium. Other speakers on the program will include:

Mr. Harvey T. Sethman, Denver, The Last Ten Years and the Outlook.
Dr. Herman I. Laff, Denver, Value of Bronchoscopy in Pulmonary Tuberculosis.
Dr. Donn J. Barber, Greeley, A Comparative Study of the Tuberculin Patch Test.
Dr. John S. Bouslog, Denver, Roentgen Therapy in Inflammatory Disease.
Dr. Frederick R. Harper, Denver, Management of Disappointing Results of Gastroenterostomy.
Dr. Herbert A. Black, Pueblo, Differential Diagnosis of Biliary Tract Disease.
Drs. Duval Prey and John M. Foster Jr., Denver, Traumatic Appendicitis.
Dr. Harry H. Lamberson, Colorado Springs, Gonococcal Infections in the Male Associated with Hypospadias.
Dr. Robert W. Dickson, Denver, Sterility in the Male.
Dr. Jack G. Hutton, Denver, Nonvenereal Syphilitic Infections.
Dr. John B. Hartwell, Colorado Springs, Diagnosis and Treatment of Vaginal Discharge.
Dr. Clifford Lee Wilmoth, Denver, Surgical Conditions of the Knee Joint.
Dr. Robert G. Packard, Denver, Trimalleolar Fractures of the Ankle with Backward Displacement of the Foot.
Dr. Lorenz W. Frank, Denver, Vocational Diseases from the Standpoint of the Internist.
Dr. Everett E. Monro, Grand Junction, Silicosis.

At the annual banquet Saturday evening Dr. Cutter will discuss "Edwin James—Pioneer Physician, Botanist and Explorer."

DISTRICT OF COLUMBIA

Chiropractor Convicted.—The District of Columbia Commission on Licensure recently reported that I. Moton Johnson, a chiropractor, was convicted of practicing medicine without a license and sentenced to sixty days in jail July 27.

Personal.—Dr. J. Winthrop Peabody resigned August 1 as superintendent and medical director of the Glenn Dale Sanatorium to devote his time to private practice. Dr. Daniel Leo Finucane, assistant superintendent, has been appointed superintendent.

The William A. White Memorial Lectures.—The superintendent and staff of St. Elizabeths Hospital and the board of trustees of the William Alanson White Psychiatric Foundation announce the first series of William Alanson White Memorial Lectures. Dr. Harry Stack Sullivan, New York, will deliver the lectures Friday evenings in the auditorium of the building of the Department of the Interior on "Modern Psychiatric Conceptions." The subjects and dates are:

October 27, Conceptions of Modern Psychiatry.
November 3, Organism and Environment.
November 10, Diagnostic and Prognostic Syndromes.
November 17, Explanatory and Therapeutic Conceptions.
November 24, Prospective Developments and Research.

Health Officer Urges Increase in Health Budget.—Health Officer George C. Ruhland recently submitted a 1941 budget of \$3,591,340, an increase of 43 per cent over the present appropriation, according to the *Washington Post*. The increase would carry out a recommendation of the U. S. Public Health Service for a \$250,000 health center for northwest central Washington, which has the highest general mortality rate in the city, and \$200,000 for a children's ward at Gallinger Hospital and better housing of interns and families of resident physicians. A fund of \$1,310,700, an increase of \$411,300 over

the present appropriation, would be used for maintenance of Gallinger Hospital, including buildings now being constructed with PWA funds. The new budget would also provide for the addition of 357 health service employees.

FLORIDA

Court Upholds Exclusion of Osteopaths from Municipal Hospital.—A municipality, according to the circuit court, eleventh judicial circuit, Florida, in the recent case of *Richardson, an osteopath, v. Miami*, may through its proper officers and agents regulate the use of the facilities of a hospital it operates and unless a practitioner can qualify under the regulations that have been adopted he may not complain to the courts over being denied admittance. No member of any school of medicine, the court pointed out, has as such a right to the privileges of a municipal hospital, and even though the Florida osteopathic practice act undertakes to accord to osteopaths "the same rights as physicians and surgeons of other schools of medicine with respect to the treatment of cases or holding of offices in public institutions" that act regulates the practice of osteopaths, not the operation of hospitals.

ILLINOIS

Nineteen Deaths from Typhoid.—Nineteen deaths have been reported in an outbreak of typhoid at the Manteno State Hospital, according to the newspapers September 16. The outbreak has been attributed to a polluted water supply at the hospital (*THE JOURNAL*, September 9, p. 1041, and September 16, p. 1138).

Supervisor of Registration Resigns to Make Hair Tonic.—Homer J. Byrd, supervisor of registration of Illinois, has resigned to "devote himself to the manufacture and sale of hair tonic and shampoo," according to the *Chicago Tribune*. He is also in the printing ink business, it was stated. Governor Horner has accepted the resignation and the position will be filled by Lucien A. File, Chester, until an appointment is made.

Chicago

Grant for Child Research.—Applications will be received up to September 30 for the Elizabeth McCormick Child Research Grant of the Institute of Medicine of Chicago. This grant makes available \$750 for some form of encouragement toward child welfare and will be awarded to a qualified investigator in the Chicago area to aid in a piece of research. Projects should in a broad sense be in the field of pediatrics. Additional information may be obtained from Dr. John Favill, secretary of the committee on the Elizabeth McCormick Child Research Grant, 122 South Michigan Avenue.

Public Meetings of the Chicago Medical Society.—The Chicago Medical Society is planning a series of public meetings at the Chicago Woman's Club Theater on Eleventh Street near Michigan Avenue at 8:30 p. m. on the first Wednesday of each month from October through April. Topics of popular interest and importance will be presented by members and guests of the society. Seats on the main floor of the theater will be reserved until 8:25 p. m. for holders of tickets. Those remaining vacant on the floor at that hour and the seats in the balcony will be open to the general public. Tickets may be obtained free on application to the office of the Chicago Medical Society, 30 North Michigan Avenue, or through one's doctor. Tickets to individual meetings or to the whole series may be requested. The program for this series of meetings follows. When only the topic is announced it is because the speaker has not been definitely selected.

October 4, Are You and Your Children Being Exposed to Tuberculosis? Where to Find Tuberculosis, Dr. Winston H. Tucker, health commissioner of Evanston.

How to Find Tuberculosis, Dr. Robert G. Bloch, Department of Medicine, Division of Biological Sciences, University of Chicago.

How to Treat Tuberculosis, Dr. James A. Britton, Northwestern University Medical School.

November 1, Famous Madcaps of History, Dr. Winfred Overholser, St. Elizabeths Hospital, Washington, D. C.

December 6, The National Health Program and Public Health.

Jan. 3, 1940, When Smallpox Comes, Dr. Victor G. Heiser, New York.

February 7, A joint meeting with the Chicago Heart Association.

March 6, A joint meeting with the cancer committee of the Chicago Woman's Club.

April 3, Infectious and Contagious Diseases and Their Relation to Chronic Disease, Drs. Archibald L. Hoyne and George H. Coleman.

In addition to this series the society is sponsoring public meetings on the economic aspects of medicine to be held in its branches under the auspices of the society, the branch and in some instances of some local organization. A debate is being arranged which will be held at the Nichols School Auditorium in Evanston under the auspices of the society, its Evanston branch, and the Lincoln School Association of Parents and Teachers November 7. A joint public meeting with the South

Chicago branch is to be held on October 29. The dates and locations of such meetings and the topics and speakers will be announced as soon as definite arrangements are made. Some of these meetings in the branches will be in the form of debates, others round table discussions and others addresses followed by open forums.

INDIANA

State Medical Meeting in Fort Wayne.—The Indiana State Medical Association will hold its annual meeting at the Shrine Theater, Fort Wayne, October 10-12, under the presidency of Dr. Edmund M. Van Buskirk, Fort Wayne. Out of state speakers will include:

Dr. Joseph Felsen, New York, The Newer Concepts of Intestinal Infection.

Dr. Byrl R. Kirklin, Rochester, Minn., Some Contributions of the Roentgen Ray to Advances in Diagnosis.

Dr. Frederick W. Clement, Toledo, Ohio, Postoperative Pulmonary Complications.

Dr. Evan G. Galbraith, Toledo, Ohio, Cause, Prevention and Treatment of Pulmonary Atelectasis.

Dr. Emmet F. Horine, Louisville, Ky., Psychologic Factors in Heart Disease.

Dr. Raphael Isaacs, Ann Arbor, Mich., Diagnosis and Treatment of Pernicious Anemia.

Dr. Willis C. Campbell, Memphis, Tenn., Surgery of the Hip Joint.

Joseph E. Schaefer, M.D., D.D.S., Chicago, Oral and Plastic Surgery.

Dr. Paul Dudley White, Boston, Diagnosis and Treatment of Cardiovascular Emergencies.

Dr. Edmund L. Keeney, Baltimore, The Medical and Surgical Treatment of Severe Bronchial Asthma.

Dr. Henry B. Orton, Newark, N. J., Bronchoscopy as an Aid to Treatment.

Among the Indiana speakers will be:

Drs. Ezra V. Hahn and Paul Merrell, Indianapolis, Diagnosis and Treatment of Peripheral Vascular Diseases.

Drs. Irvine H. Page and Kenneth G. Kohlstaedt, Indianapolis, The Sulfapyridine Treatment of Pneumonia.

Dr. Robert V. Hoffman, South Bend, The Serum Treatment of Pneumonia.

Dr. Frank H. Green Jr., Rushville, The Diagnosis and Medical Management of Ectopic Pregnancy.

Dr. Paul S. Johnson, Richmond, Fatigue, Its Causes and Treatment.

Dr. Robert G. Moore, Vincennes, The Heart Neuroses, Their Diagnosis and Treatment.

Dr. Roscoe L. Sensenich, South Bend, Diagnosis and Treatment of Peptic Ulcer.

Dr. Clair L. Ingalls, Washington, Specific Primary Peritonitis.

Dr. Frank L. Jennings, Oaklandon, Collapse Therapy of Pulmonary Tuberculosis.

Dr. Maurice S. Schulhof, Muncie, Renal Anomalies from a Surgical Standpoint.

Dr. Fred A. Thomas, Indianapolis, Complications Following General Anesthesia.

Dr. Everett T. Zaring, Terre Haute, Who Should Choose the Anesthetic?

At the annual banquet Wednesday evening the speakers will be Dr. Nathan B. Van Etten, New York, President-Elect, American Medical Association, and George Lang, Ph.D., professor of philosophy, University of Alabama, University, "Twentieth Century Medicine Man." At the meeting of the woman's auxiliary, the speakers will include Dr. Edgar F. Kiser, Indianapolis, on "A Brief Sketch of the History of Medicine," and Louis A. Warren, director of the Lincoln Museum, "The Woman Who Influenced Lincoln Most." Entertainment will include various fraternity luncheons and a skeet and trap shoot.

KANSAS

Society News.—At a meeting of the Sedgwick County Medical Society September 19 the speakers were Drs. Harold F. O'Donnell, Wichita, on "Sulfapyridine in the Treatment of Gonorrhea" and Robert H. Maxwell, Wichita, "Ten Year Study of Cesarean Section in Sedgwick County."

New Tuberculosis Unit.—The new \$425,400 Kinney Memorial Hospital was dedicated at the Kansas State Sanatorium for Tuberculosis, Norton, August 23. With 253 beds furnished by the new unit, the sanatorium now has a total of 563 beds. The speakers at the exercises included Governor Payne Ratner and Dr. Howard L. Snyder, Winfield.

NEBRASKA

Annual Clinical Meeting in Omaha.—The seventh annual assembly of the Omaha Mid-West Clinical Society will be held October 23-27. Among speakers listed in a preliminary announcement are: Drs. Charles Anderson Aldrich, Winnetka, Ill., pediatrics; William Wayne Babcock, Philadelphia, and Elliott C. Cutler, Boston, surgery; Clifford J. Barborka, Chicago, William R. Houston, Austin, Texas, and Samuel A. Levine, Boston, medicine; Frank E. Burch, St. Paul, eye, ear, nose and throat; Louis J. Karnosh, Cleveland, neurology; Clarence R. O'Crowley, Newark, N. J., genito-urinary disorders; Grandison D. Royston, St. Louis, gynecology and obstetrics; Walter Schiller, Chicago, basic sciences, and James S. Speed, Memphis,

Tenn., orthopedic surgery. There will also be a symposium on preoperative and postoperative treatment presented by Drs. William L. Estes Jr., Bethlehem, Pa.; John S. Lundy, Rochester, Minn.; Walter G. Maddock, Ann Arbor, Mich., and John R. Paine, Minneapolis.

NEW JERSEY

Camden Schools Closed Indefinitely.—The New York Times reported September 16 that public and parochial schools in Camden would be closed indefinitely because of infantile paralysis. Ninety-one cases have occurred in the county since July 1 with ten deaths. Schools in Camden and several suburbs had delayed opening until September 18 because of the prevalence of the disease.

NEW YORK

Course in Organic Neurology.—Dr. Wardner D. Ayer, Syracuse, will give a course on organic neurology for the Schoharie County Medical Society, Cobleskill, and the Montgomery County Medical Society at Amsterdam on six Tuesdays beginning September 26. The course is given under the auspices of the committee on public health and education of the Medical Society of the State of New York, of which Dr. Thomas P. Farmer, Syracuse, is chairman. Subjects of Dr. Ayer's lectures will be:

- September 26, The Brain and Spinal Cord.
- October 3, (a) The Neurologic Examination and (b) The Lumbar Puncture and Examination of Spinal Fluid.
- October 10, Acute Infectious Processes.
- October 17, Cerebral Hemorrhage and Thrombosis, Cerebral Trauma, Cerebrospinal Syphilis and Parkinson's Disease.
- October 24, The Brain Tumor, Brain Abscess and Epilepsy.
- October 31, Spastic Paraplegia and Diseases of the Spinal Cord, Peripheral Neuritis and Pathology of the Intervertebral Disk.

New York City

Personal.—Henry S. Pritchett, Ph.D., president emeritus of the Carnegie Foundation for the Advancement of Teaching, died August 28 in Santa Barbara, Calif., aged 82 years.—Dr. Charles F. McCarty, Brooklyn, recently medical director of the city department of welfare, has been appointed associate director of medical activities of the Medical Society of the County of Kings.

Short Courses for Practitioners.—The New York Postgraduate Medical School announces short courses varying from five days to a month or more, full time, in arthritis and rheumatic diseases, October 2-6; internal medicine, October 2 to November 30; neurology, the month of October; orthopedics, October 9-14. In addition, the graduate school offers part time courses for local physicians in bacteriology, dermatology and syphilology, gynecology, medicine, neurology and psychiatry, ophthalmology, orthopedics, otolaryngology, pathology and pediatrics. Address inquiries to the Director, 309 East Twentieth Street, New York.

Dr. Rhoads to Succeed Dr. Ewing at Memorial Hospital.—The board of managers of Memorial Hospital for the Treatment of Cancer and Allied Diseases has announced that Dr. Cornelius P. Rhoads, an associate member of the Rockefeller Institute for Medical Research, has been appointed director of the hospital to succeed Dr. James Ewing, who will soon retire. Dr. Rhoads is 41 years old and graduated from Harvard Medical School in 1924. He has been on the staff of the institute since 1928. Dr. Ewing, who was professor of pathology at Cornell University Medical College from 1899 to 1932 and has since been professor of oncology, has been director of Memorial Hospital since 1932.

Grants for Research on Diabetes.—The New York Diabetes Association announces that it has available three grants up to \$500 each for research in diabetes. These grants may be used for the purchase of apparatus and supplies needed for special investigations and for the payment of unusual expenses incident to such investigations, including technical assistance, but not for providing apparatus and materials which are ordinarily a part of laboratory equipment. The research must be carried out in Greater New York, though the men engaged in it need not be residents of Greater New York. There are no formal application blanks, but letters of application must state definitely the qualifications of the investigator, an accurate description of the proposed research, the amount requested and the specific use of the money to be expended. It is desirable to include a list of persons with whom the applicant has been associated and who would be willing to give letters of recommendation and sponsor the applicant. Applications should be mailed to the Committee on Research, New York Diabetes Association, Inc., 22 East Fortieth Street, New York. Applications will be received up to November 1.

OHIO

Society News.—Dr. Tinsley R. Harrison, Nashville, Tenn., addressed the Academy of Medicine of Cleveland and Cuyahoga County Medical Society September 15 on "The Clinical Approach to the Hypertensive Patient."—Dr. Barney J. Hein, Toledo, addressed the Summit County Medical Society, Akron, September 5, on "Medical Economics as Viewed in Ohio."—Dr. Russel G. Means, Columbus, addressed the Marion Academy of Medicine September 6 on "New Conceptions of Otitis Media."

Postgraduate Day in Canton.—The second annual Postgraduate Day sponsored by the Stark County Medical Society will be held in Canton October 11. The following members of the faculty of Jefferson Medical College, Philadelphia, will be the speakers:

- Dr. George P. Müller, professor of surgery, Present Status of Surgical Treatment of Peptic Ulcer.
- Dr. Martin E. Rehfuss, clinical professor of medicine, Medical Aspects of Gallbladder Disease.
- Dr. Hobart R. Reimann, Magee professor of the practice of medicine and clinical medicine, Recent Developments in the Treatment of Pneumonia.
- Dr. Brooke M. Anspach, professor of gynecology, Medical and Surgical Treatment of Pelvic Disease.

New Public Health Council.—Governor Bricker has appointed a new public health council in accordance with a new law reorganizing the state's health service. Members are Drs. Clyde L. Cummer, Cleveland; Ward D. Coffman, Zanesville; Russel G. Means, Columbus; Mrs. C. Tracy LaCost, Toledo, president of the Ohio Congress of Parents and Teachers; S. F. Ridings, D.D.S., Greenville, and Mr. William Helmer, sanitary engineer, Cincinnati. The new law requires that the state health director be appointed by the governor from a list recommended by the health council and that the health director cannot be removed except on recommendation of the health council. Dr. Roll H. Markwith, the incumbent director, was reappointed for the five year term set by the law.

PENNSYLVANIA

Medical Service Plan Chartered.—The Medical Service Association of Pennsylvania was chartered by the Dauphin County Court in Harrisburg September 7, newspapers report. The new plan is sponsored by the Medical Society of the State of Pennsylvania. Offices will be opened in Harrisburg and Philadelphia within a few weeks, it was said. Persons eligible for the service are those earning less than \$60 a week if they have dependents and those earning less than \$30 if they do not have dependents. Individual as well as group memberships will be available. Rates will begin at \$2.50 a month for single persons, \$4.50 for married couples, \$1.50 for the first child and \$1 for each additional child or dependent.

District Meeting.—The annual meeting of the Fifth Council District of the Medical Society of the State of Pennsylvania was held in Abbottstown at the Hanover Country Club August 24. Dr. Carl E. Ervin, Harrisburg, spoke on "Diabetes and the General Practitioner," and Drs. John J. Shaw, secretary, and Alexander H. Stewart, deputy secretary of health, explained the program and functions of the state department of health. Dr. David W. Thomas, Lock Haven, president, and Dr. Walter F. Donaldson, Pittsburgh, secretary of the state society, spoke on "Medicine Faces a Crisis" and "The National Scene" respectively; Dr. Chauncey L. Palmer, Pittsburgh, chairman of the society's committee on public legislation, "Public Assistance Medical Service in Review" and Mr. Lester H. Perry, Harrisburg, managing editor, *Pennsylvania Medical Journal*, "Insured Medical Service in Prospect."

SOUTH CAROLINA

Personal.—Dr. Archie B. Hooton, Upper Marlboro, Md., has been made health officer of Allendale and Hampton counties, taking over part of the work of Dr. Louis T. Claytor, who has been in charge of these counties as well as Barnwell and Bamberg counties. Dr. Claytor will remain as health officer of the latter two counties.—Dr. James C. Brabham, Johnsonville, has been appointed health officer of Lexington County. This county was formerly joined with Calhoun County in a health unit under the direction of Dr. Frank L. Geiger, St. Matthews, who remains in Calhoun County.

Society News.—Dr. Grady N. Coker, Canton, Ga., addressed a joint meeting of the Greenville County medical and dental societies in Greenville August 7 on "Modern Trends in Medical Practice" and George Albright, D.D.S., Greenville, on "Diseases and Accidents In and Around the Mouth."—The

Columbia Medical Society held its August meeting at the South Carolina State Hospital with the following program by members of the staff: Drs. Chapman J. Milling on paranoia; Joe E. Freed and William S. Hall, metrazol therapy in mental diseases; John T. Cuttino, bromides—mental disorders, and William M. Fox, dementia paralytica.

American Legion Honors Dr. Wilson.—The American Legion, department of South Carolina, will confer its 1939 plaque for distinguished service to South Carolina on Dr. Robert Wilson, dean and professor of medicine, Medical College of the State of South Carolina, Charleston. Dr. Wilson graduated from the college in 1892 and has been associated with it since 1899, first as a member of the teaching staff and since 1908 as dean. He was president of the Medical Association of South Carolina, 1904-1905; Southern Medical Association, 1915-1916, and of the Tri-State Medical Association of the Carolinas and Virginia, 1927-1928. He was chairman of the state board of health from 1907 to 1931.

TENNESSEE

New Health Officers.—Dr. Robert D. Hollowell, health officer of Charlottesville and Albemarle County, Va., has been appointed health officer of Shelby County.—Dr. Albert L. Ball, Gallatin, has been appointed health officer of Bradley County to succeed Dr. William C. Sanford, Cleveland, who resigned.—Dr. James A. Loveless, recently of Chattanooga, has been appointed district health officer of Rhea-Meigs County, succeeding Dr. Edwin N. Haller, Decatur.

VIRGINIA

Personal.—Dr. Sylvester P. Gardner, Derby, was honored with a testimonial dinner given by friends at the Community Club House, Big Stone Gap, recently, marking his retirement after twenty-one years on the medical staff of the Stonega Coke and Coal Company.—Dr. Joseph Grice, Portsmouth, has resigned as medical director of the city schools and has been succeeded by Dr. Russell M. Cox.

Society News.—At the quarterly session of the Southside Virginia Medical Association in Burkeville September 12 the speakers were Drs. Thomas F. Wheeldon, Richmond, on "What Message Should the Specialist Carry to the General Practitioner in Regard to the Treatment of Arthritis?"; Warren T. Vaughan, Richmond, "Allergic Dermatoses"; Albert V. Crosby, Norfolk, "Penetrating Wounds of the Thorax"; James M. Hutcherson, Richmond, "Spontaneous Pneumothorax Simulating Acute Coronary Occlusion," and Arnold F. Strauss, Norfolk, "Epituberculosis."

State Medical Meeting in Richmond.—The Medical Society of Virginia will hold its seventieth annual session October 3-5 in Richmond with headquarters at the John Marshall Hotel. The house of delegates will meet Tuesday October 3. There will be general sessions Wednesday and Thursday mornings, medical and surgical sessions separately Wednesday afternoon and a general session Thursday afternoon followed by round table discussions. Speakers at the general sessions will be:

Dr. Franklin M. Hanger Jr., New York, Differential Diagnosis of Jaundice.
Dr. Eugene M. Landis, Charlottesville, subject not announced.
Dr. Charles H. Peterson, Roanoke, Diagnosis and Treatment of Mediastinal Tumors.
Dr. Henry B. Mulholland, Charlottesville, The Use of Protamine Insulin in Treatment of Diabetes Mellitus.
Dr. Richard P. Bell, Staunton, Experience with Thyroid Disease in Western Virginia.
Dr. Mont R. Reid, Cincinnati, The Cancer Problem.
Dr. Louis Hamman, Baltimore, a clinicopathologic conference.

Dr. Alexander F. Robertson Jr., Staunton, will deliver his presidential address at the opening session on "The Changing Era in Medical Economics." Dr. Claude Moore, Washington, D. C., will address the surgical section on "The Operability of Gastric Malignancy."

WASHINGTON

Society News.—Dr. Morris Fishbein, Chicago, Editor of THE JOURNAL, will address a special meeting of the King County Medical Society, Seattle, September 28, at a luncheon at the Washington Athletic Club on "American Medicine and the National Government." Speakers at the regular meeting September 18 were Drs. John W. Geehan, on "Ruptured Abdominal Aortic Aneurysm Producing Intestinal Obstruction"; Joel W. Baker, "Carcinoma of the Colon," and Kenneth K. Sherwood, "Source, Distribution and Symptoms of Skeletal Metastasis."

GENERAL

Prevalence of Poliomyelitis.—The U. S. Public Health Service received reports of 479 cases of poliomyelitis in the United States during the week ended September 2 as compared with 391 the preceding week and a median of 333 for the corresponding week of the years 1934-1938. States with the highest incidence were: Michigan 109 cases, New York 100, Minnesota sixty, California fifty, Pennsylvania forty-four and Ohio eleven. New Jersey reported only ten cases for the week, Illinois nine, Texas eight and South Carolina six.

Food and Drug Officials Meet.—The forty-third annual conference of the Association of Food and Drug Officials of the United States will be held in Hartford, Conn., September 26-29 at the Bond Hotel. Among the speakers will be George R. Cowgill, Ph.D., New Haven, Conn., a member of the Council on Foods of the American Medical Association, on "Food and Drug Law Problems as Viewed by the Student of Nutrition"; Mr. W. G. Campbell, chief, U. S. Food and Drug Administration, Washington, D. C., "Looking Ahead in Food, Drug and Cosmetic Control," and Dr. Knox E. Miller of the Federal Trade Commission, Washington, "Advertising and the Consumer."

Society News.—Dr. Nathan H. Polmer, New Orleans, was chosen president-elect of the American Congress of Physical Therapy at the annual meeting in New York September 5-8 and Dr. William H. Schmidt, Philadelphia, was installed as president. Vice presidents elected were Drs. Fred B. Moor, Los Angeles; Kristian G. Hansson, New York; Miland E. Knapp, Minneapolis; Walter S. McClellan, Saratoga Springs, N. Y., and Walter J. Zeiter, Cleveland. Gold keys for research during the past year were awarded to Drs. Edward C. Titus and A. Bern Hirsh, New York; Joseph Riviere, Paris, and James B. Mennell, London. A gold medal was awarded to Dr. Henry W. Meyerding, Rochester, Minn., for an exhibit on etiologic factors in backache.

Look Out for Swindler Wanting Morphine.—A physician of New Rochelle, N. Y., reports a swindler who visits physicians to obtain morphine and atropine for asthmatic attacks and gives worthless checks in payment. The First National Bank of Philadelphia reported that more than thirty checks had been received from physicians in northern New Jersey, New York and the New England states. He uses the name Arthur G. Kuhn, is about 5 feet 8 inches tall and weighs about 130 pounds. He appears to have chronic asthma. He says that he is passing through a town on a truck, giving the name of a transportation company. In New Rochelle he gave the name of Langroth Transportation Company, 236 Spring Garden Avenue, Philadelphia. The Philadelphia bank reported that neither this firm nor the address could be located. In other instances he mentioned the Kuhn Express Delivery Service.

Government Services

Physicians Wanted for CCC Camps

A recent decision by the director of the Civilian Conservation Corps and the War Department permits the employment of physicians who are not medical reserve officers. Previously medical service in the CCC has been furnished by medical reserve officers with the exception of a few physicians employed on a contract basis. Employment may now be offered under the rating of civilian employees or on a contract basis, the initial pay being \$2,600 a year. No quarters for families are provided and the physician will be required to pay for his meals at camps. Temporary quarters for him will be provided at a nominal fee. Those selected will be required to pay their own travel expenses to the nearest district headquarters, where they will be put on temporary duty for instructional purposes before being sent to camps. If the services rendered are satisfactory, the employment is more or less permanent. Duties at camps are the medical care of the enrollees and preventive medicine. To be eligible, a physician must be legally qualified to practice medicine and physically able to perform the duties. Physicians interested are requested to submit their applications to the office of the Surgeon, Headquarters, Seventh Corps Area, Federal Building, Omaha, giving the date when they will be available and preference of assignment in the following states: Minnesota, North Dakota, South Dakota, Iowa, Nebraska, Missouri, Kansas and Arkansas.

Foreign Letters

LONDON

(From Our Regular Correspondent)

Sept. 4, 1939.

The War

We have been at war with Germany since yesterday. These letters are concerned only with the medical aspects and have previously dealt almost entirely with the arrangements for the defense of the civilian population against air raids: problems of organization even greater than those of the armed forces. After ten months of extraordinary effort a "knock out blow" against the most urbanized population of Europe has become impossible. Steel shelters to protect 6,500,000 people have been distributed free to dangerous areas and soon there will be sufficient for 10,000,000. Every firm employing more than fifty persons is compelled by law to plan suitable shelter for them. Arrangements were made for the transfer in four days from dangerous areas of 3,000,000 persons, including all the children, blind persons and expectant mothers, and for their feeding and medical care. For every hundred thousand persons there were sixty men and women trained in first aid work and forty men trained in rescue work. For civilian casualties 200,000 beds were available within twenty-four hours and the number will be increased to 300,000. Gas masks have been produced, fitted and distributed to the whole population, and protective helmets for babies to the number of 1,500,000. Busses, coaches and tradesmen's vans have been prepared in thousands for conversion into ambulances, and stretcher bearers and first aid personnel have been trained for them. A vast organization of trained and equipped observers, police and sirens renders a surprise attack impossible. The port of London has organized special protection for its 30,000 employees. Rationing of food will at once begin. For this purpose 80,000,000 ration cards and 19,000,000 forms for householders have already been printed. All this elaborate organization has been built up in four years and at an accelerated rate in the last year. For a week it has been ready for action at an hour's notice. Hundreds of thousands of trained civilians at their daily work are ready to become whole time workers in the plan if the order comes. The evacuation of the school children and others from dangerous areas, a scheme involving 30,000,000 persons which has never been performed on this scale in the history of the world, has been completed without a hitch and indeed with clocklike precision. The children were taken from the schools in coaches to the railway stations and to the country by trains reserved for them, ordinary traffic being largely suspended. As one train went out another took its place. First aid parties were in attendance but had little to do. The evacuation of the patients from the hospitals of London and other cities was performed with similar celerity and smoothness, according to prearranged plans. As typical may be taken the evacuation of the Middlesex Hospital, London. Coaches arrived at 9 a. m., for which patients on stretchers were waiting in the great hall. All the ambulant patients had been taken away in cars provided by friends of the hospital. There still remain a few patients too ill to be removed. A strong subbasement protected against gas is ready for the casualties of air raids. At Guy's and Bartholomew's hospitals, hundreds of students were to be seen engaged in stacking sandbags and completing other defensive arrangements.

Underground Operating Room in London

An underground operating room, for use in war time, is being built under the foundations of a new block of buildings at the Hospital for Sick Children, Great Ormond Street. The underground accommodation, the first of its kind in England, will consist of a receiving room with eighty seats and six dressing rooms where minor injuries can be treated; an oper-

ating room for major casualties with three tables and nine dressing and anesthetic cubicles; a duty room for the staff, and a sterilizing room. The electric light and water supply are from sources independent of the main service.

The Effect of Sulfonamide Derivatives on Aircraft Pilots

The fact that sulfonamide derivatives, by producing methemoglobin or sulfhemoglobin, may interfere with oxygen exchange of blood and so prove a danger to aircraft pilots is a subject of correspondence in the *British Medical Journal*. Dr. E. P. Mackie, medical adviser of Imperial Airways, saw a pilot who was suffering from symptoms of severe anoxemia as a result of flying at an altitude of only 13,000 feet. It was found that he had been taking full doses of sulfanilamide for tonsillitis. It is stated that a full dose of one of the sulfonamide derivatives taken shortly before flying lowers an aviator's "ceiling" by about 5,000 feet. Mackie therefore recommends that passengers, and more particularly members of the crew of an aircraft, should be warned against taking these drugs within a few days of flying.

Dr. A. F. Rook, Central Medical Establishment, Royal Air Force, refers to a personal communication received by him nearly two years ago from Dr. V. E. Lloyd, who found symptoms of intolerance from sulfanilamide in lorry drivers, which sometimes affected their judgment of speed and distance. Instructions were immediately issued to all medical officers of the Royal Air Force that no one should be allowed to fly or drive automobiles while taking these drugs. Similar cases have been observed in America and Germany.

Fracture Services

The committee appointed by the government on the rehabilitation of persons injured by accidents has presented its report. As fractures and allied injuries are by far the most important causes of disablement, they have received most attention. The system, universal until a comparatively recent date and still prevalent in the hospitals, by which fractures are treated in the general surgical wards and under general surgical routine is held to be gravely defective. Special fracture services should be organized throughout the country, as already has been done in a number of hospitals. They should be based on three principles: 1. All fractures, except those of the head, should be segregated in a single department. 2. The service should be operated and controlled by a single team under a surgeon in charge. 3. Treatment should be continued until restoration of working capacity has been effected to the fullest possible extent. While not dissenting from the view that a fracture service is susceptible of extension to other injuries, such as those of the hands and fingers, and may be ultimately desirable, the committee insists that a general traumatic service is not called for and under present conditions is impracticable. The modern fracture service should be based on concentration of cases in one department under single control, continuity of treatment and supervision until working capacity has been restored to the fullest possible extent. The principles of treatment aim at securing in every case exact reduction, fixation and immobilization of the broken part in correct position, and active movement from the earliest possible moment of the uninjured part of the limb, to prevent wastage of muscles and stiffness of joints.

In a hospital of from 500 to 1,000 beds the surgeon in charge of the fracture clinic should be paid an honorarium of \$2,500, and in one of from 200 to 500 beds, \$1,500. As the hospital is a voluntary one the surgeon would not receive any remuneration for his ordinary work, but it is pointed out that the surgeon in charge of a fracture clinic will have to undertake much more onerous and time-consuming duties than those usually falling to the lot of a visiting surgeon to a hospital.

RESTORATION OF FUNCTIONAL ACTIVITY

After-care following the surgical treatment for securing union of the fracture is held to be of vital importance and should be directed and supervised by the surgical team responsible for the initial treatment. Physical therapy is useful but occupational therapy may be more important and should be undertaken at rehabilitation centers rather than in hospitals. So far as hospital after-care is concerned, the provision of remedial exercises has mainly been considered. The fracture clinic should have its own gymnasium for remedial exercises and its own physical therapy department. But exercises, which are an essential part of the rehabilitation process, can be applied with limited accommodation and the simplest equipment.

UNDERGRADUATE AND GRADUATE INSTRUCTION

The committee holds that the training of students in fracture work is seriously deficient. A period of teaching in the fracture department, which should be part of every teaching hospital, should be obligatory. For graduate instruction the committee recommends (1) a session on fracture treatment to be regularly included in the refresher course for insurance practitioners and (2) a center for research and graduate instruction to be established in London.

PARIS

(From Our Regular Correspondent)

Aug. 12, 1939.

Fostering International Medical Relations

The general assembly of the Association for the Fostering of Medical Relations was held this year in the council chamber of the Faculty of Medicine of Paris with the minister of public health as chairman. This association was founded in 1922 to facilitate contacts between French physicians and their colleagues in other countries. Its first concern was to create, at the faculty of Paris, an information bureau to make medical visits to Paris useful to foreign physicians by furnishing information on courses, conferences and current medical facts. This information is furnished in different languages and by correspondence. Last year nearly 3,500 physicians from all parts of the world consulted it, not counting 2,000 others who made use of its services by mail. It is planned to create a sort of medical club for visiting physicians in the coming year. The association maintains a library, exchanges scientific publications, secures publicity abroad for important French articles and books, arranges visits of French physicians at foreign medical faculties and vice versa. It has organized courses in English and Spanish in the different branches of medicine.

Jayle, at the general assembly, remarked that our age is inferior to that of antiquity on the score of cultural friendship, because of the lack of a universal language such as Greek and Latin were formerly for the Western world or Arabic for the Eastern. The association, therefore, lays stress on the only means remaining to facilitate the mutual understanding of scholars, namely, the general use of English, German and French. Jayle related that when he was visiting one day in Berlin, Ehrlich invited him to attend one of his lectures and began to say in French "Gentlemen, we have the pleasure of receiving a Paris physician. I am going, therefore, to lecture in French and will then make some explanations in German for the few among us who do not understand French." The world has lost this charm and skill of linguistic readiness. One must recover these happy times. For this purpose, Jayle added, three essential tasks should be vigorously prosecuted: exchange of scientific publications, exchange of students and exchange of professors. This year American works will appear in the large French medical journals. The same applies to the interchange between France and Japan. In the exchange of students and professors, the language will always constitute the great obstacle. It is for this reason that a knowledge of

foreign languages should be required of all students who intend to devote themselves to scholarship and research. Among these languages, the study of Greek and Latin ought not to be neglected, for "traveling through time is just as useful as traveling through space."

The Third French Congress of Ophthalmologists

The meeting of the third French Congress of Ophthalmologists took place in May. Coutela's paper dealt with the eye and occupational diseases. He showed how ocular lesions are related to other industrial accidents and intoxications due to manual work. Industrial dermatoses often predominate about the eyelid. Some of these dermatoses are purely toxic; others develop only when an individual predisposition is present. The number of mineral, animal, vegetable or chemical substances by which the eye or its adnexa can be injured has increased during the last years with the progress of industrial manufactures. Radiations, whether visible or invisible, natural or artificially produced, form part of the pathologic picture. Besides traumas, or lesions caused by external agents, the eye suffers during general intoxications. In certain diseases, such as miners' nystagmus and the ocular cramp of mechanics working with precision instruments, the oculomotor apparatus or the sensory elements of the visual apparatus alone are affected. Such conditions make necessary measures of industrial and medical prophylaxis and give rise to important medicolegal consequences.

Among other papers read, attention is called to the apparatus presented by Baillart and Bideau for measuring ocular temperatures during thermo-electrical connection and the description of the extraction of a cataract by means of Arraga's cupping glass, explained by Binet and De Saint Martin.

Meeting of Hydrologists

The sixteenth International Congress on Hydrology, Climatology and Medical Geology will be held at Strasbourg October 8-13. Among the questions to be discussed are those of the hydromineral therapy of dermatoses, mineral waters in petroliferous regions and the development of French thermal machinery in the last twenty years. Since France is at present under arms, the majority of scientific meetings scheduled for September have been postponed or canceled.

News of the Universities

Regulations affecting the universities are increasing in number. A new decree revises the regulations of the outside activities and fees of university teachers, e. g. those of university medical men and of academic experts with a private practice. The main features of this decree are as follows: Whenever university teachers are called to make investigations and to render expert opinions in matters pertaining to their specialty, without being under legal obligations to do so, their activity is to be regarded as within the sphere of their professional functions and requires no ministerial permission (THE JOURNAL, July 29, 1933, p. 381). Expert opinions rendered to foreigners as well as those rendered outside their academic specialty are subject to the approval of the minister of arts and sciences for the reich. Directors of university clinics are permitted privately to treat patients of the first and second classes (paying patients) and to charge a fee whenever patients prefer personal attention; otherwise, treatment of the patient can be taken care of by an assistant. In addition to this, directors of university clinics may maintain office hours, such as is usual for practitioners. However, if these office hours take place outside their clinics, ministerial permission must be sought. Beyond these possibilities, directors of university clinics may not engage in private practice; for example, they may not make professional calls

at the home of the patient. For using state equipment, materials and personnel, directors must pay a certain percentage of their subsidiary income to the state treasury.

The German student body has resigned from the International Student Service, with which it had cooperated since 1936. The reason assigned was "that the service had manifested a growing anti-German tendency, especially in the sphere of social work among students. It was felt that the service concentrated its attentions on the 'German' students abroad who had preferred, from racial or political reasons, to leave Germany." (The International Student Service, as it is well known, has endeavored to assist students who were compelled to leave Germany.)

As pointed out previously, some universities had adopted regulations limiting enrolment (THE JOURNAL, May 8, 1937, p. 1664). These provisions, however, decreased university enrolment for academic vocations to such a degree that an annual deficit of from 5,000 to 8,000 students has resulted. In consequence, these entrance requirements have now been abolished and the way opened to unlimited enrolment. Besides, student attendance at the universities in most cases did not reach the quotas fixed: In 1933 Germany had 116,000 regular university students; in 1934, 95,000; finally, not even 60,000, an attendance insufficient to take care of the country's future professional needs.

The prospects for the higher education of women were recently discussed by Dr. Margarete Esch, academic and vocational adviser for women at the University of Berlin. The number of female students has greatly fallen since 1933. Of the 1,612 young women who began their studies in the winter semester of 1936-1937, 425 intended to become physicians.

The student session representing the whole of Germany that met in May in Würzburg considered the question of the higher education of women. Mrs. Scholtz-Klink, who occupies a leading position in the nationalistic party as leader of women for the reich (reichsfrauenführerin), emphasized that women engaged in work for the common good may not stint their work by evaluating too closely their own services; the present-day spirit and aim was to secure "a Germanic equality" of women with men. Women throughout the nation may engage in all types of work in which their strength is in keeping with the requirements of the job. The leader of the bureau dealing with female students nevertheless said that marriage and family remained woman's ultimate vocation. At this point the applause of the men in the audience was especially vigorous; likewise, when the speaker encouraged her comrades to enhance their charms by means of suitable clothes.

At this student session, apart from several manifestations of a political nature, the struggle for the control of university ideals was clearly reflected. Besides students from old Germany, Austrian and Sudetenland students were in evidence, clad in blue-gray shirts; and numerous so-called volksdeutsche studenten, that is, students of German descent belonging to other countries, among them those from Poland, wearing white shirts, black trousers and black ties. In addition there appeared a numerous group of young fascists and Japanese, South African, Finnish, Hungarian, Bulgarian and Yugoslavian contingents. In place of the student clubs that formerly existed and boasted honored traditions and names and which had been abolished when the present political party came into power, the new "comradeships" that had taken their place were at this time given partly historical names like Hutten, York, Körner and Bismarck, partly names of "martyrs in the national socialistic cause," though these had no connection whatever with education. Reich's leader Alfred Rosenberg admitted that there had existed in the earlier history of Germany great epochs that were molded by Christianity, but at the same time he made it clear that these epochs represented bygone and closed movements with which the Germans of today had no direct connection. The awakening of the German nation had been so profound that the German people had broken with these traditions. However,

national socialism, he went on to say, motivated by traditional ties, had refrained from destroying monuments that embodied a great epoch of the past. The touch-stone of loyalty to the party in power was, he said, to make an issue of Judaism. This issue had to be fought to its bitter consequences without relenting.

The great majority of universities and their representatives assumed a negative attitude toward national socialism in 1933 or at least temporized. Consequently, when national socialism took over political power, the differences between the previously dominating cultural stratum of society and the new political leadership appeared to be greater than ever before. Not only the traditional forms of student life but also the universities with their claims to scientific objectivity and intellectual autonomy were drawn into the current of the new social forces. The picture of the universities has greatly changed within the last six years. About 45 per cent of the university teachers, as Professor Mentzel, the new leader of the division of arts and sciences in the department of education of the reich, announced, were replaced either for political reasons or on account of old age.

The unrest of the first years after 1933 in university life is now regarded in leading circles as terminated. Nevertheless, the students do not consider the revolution of the universities as concluded and in decisive positions as not even begun. The underlying causes cannot be fully understood at first glance. The ultimate aim is a fundamental revision of all values heretofore regarded as of absolute applicability, such as "mind" and "education." These terms, it is said, require a new national socialistic interpretation to mediate between a onesided acceptance and a premature rejection. Not until this has been done will the universities take the position due them among the important factors of the third reich. Scientific research, the national socialists say, has in the past been reproached with having become estranged from the common life of the people. Nazi students, on the other hand, have moved it closer, often into proximity with the political tasks of the nation. Science and scholarship are not to be subordinated to politics but fitted into it just as culture today is regarded as a part of character training. This, however, in reality implies a new gradation of values. Instinct and energy are not to be dominated but supported and strengthened by knowledge. Knowledge is to be put at the service of instinct and energy. It is in this direction that national socialism guides the mental life of the students.

ITALY

(From Our Regular Correspondent)

Aug. 15, 1939.

International Congress of Comparative Pathology

The fourth International Congress of Comparative Pathology was held recently in Rome. The royal family, the academicians of Italy and representatives of the Italian universities were present. The first official topic was virus diseases. Professor Lépine discussed immunity to virus diseases. Professors Stanley and Loring spoke on the properties and nature of purified virus. Large amounts of crystalline, purified virus have been obtained from the tobacco mosaic. Its activity depends on its protein structure. There are two theories on the nature of the viruses, namely (1) that they are autocatalysts and (2) that they are living agents of intramolecular (rather than of intermolecular) structure which originate in abiogenesis or else from organisms in retrograde evolution.

The second topic concerned functions of associated antigens in relation to immunity. Professor Lanfranchi has proved that *Bacillus subtilis* fixes the virus of influenza equina in vitro and also that *Bacillus subtilis* antigen is useful for the production of immunity against influenza in horses. Professor Marrack spoke on the reactions between antigens and antibodies. Professor Ramon said that he observed that the value

of specific immunity increases when the antigen is administered in association with a stimulating substance which causes a local inflammation at the point of the injection. The diffusion of the toxin is gradual, owing to the presence of the reaction, and the resulting antitoxic immunity develops more quickly and intensely. The method has been used to obtain rapidly strong antitoxic serums, in the vaccination of animals against tetanus and for a better preparation of anticarbuncle vaccines. Since the establishment of a "synergy between antigens," the knowledge on immunity has progressed so that it is possible at present to perform multiple immunizations of reciprocal reinforcing action by means of only one series of injections.

The subject of the third topic was pathologic heredity. Professor Hirsfeld spoke on serologic mutations in the formation of blood groups. Iso-agglutinability of erythrocytes of the blood of group O can be due to incomplete mutation of hereditary factors (genes) of the O type. Professor Chiarugi discussed vegetal pathology in relation to human pathology. The immunity and morbidity of persons who are in contact with pathogenic agents depend on the individual secretion of specific factors by which either the organic resistance or the susceptibility to the disease is increased. The degree of pathogenicity of the parasites is also in genetic gradation. Therefore diseases are the result of the interference of genetic factors of the host and of the parasites. The hereditary resistance of plants to diseases can be increased by hybridization of samples and selection of hybrid plants.

For the fourth topic there was a discussion on processes of regression in plants.

Antidiphtheritic Vaccination

The legislative committee of the Upper House of Representatives assembled to discuss the advisability of making antidiphtheritic vaccination compulsory. Prof. Buffarini Guidi, subsecretary of state for internal affairs, said that the principle of making the vaccine compulsory has been established in Italy for the last few years. There was a ministerial law in 1929 by which the local authorities had the right to make vaccination compulsory whenever it would seem advisable for prevention of diphtheria. The department of public health, before presenting the project to the house, asked for advice from eminent groups of technicians, especially members of the Council of Public Health, and other medical authorities. In numerous cities and provinces in which the vaccination has been compulsory, there has been no inconvenience and no harm has been done up to now. The vaccine is prepared under supervision of the government. The number of people in Italy who have been vaccinated is about 300,000. Several senators took part in the discussion, after which the project of law was approved.

Research on Peyote

Professor Palmieri, head of the Istituto di Medicina legale of the University of Bari, carried on systematic researches on the toxicity of mezcaline and of the total extract of peyote (*Echinocactus williamsi*). He reported his results before the first Congress of Social and Legal Medicine, recently held in Bonn.

Peyote is a native cactus of the southern part of the United States and northern part of Mexico. The drug was ingested by natives in the precolumbian era as a sacred plant in certain ceremonies. Some native Mexican groups still use it.

Peyote produces a state of intoxication with two different phases: one of general stimulation with euphoria and the other of cerebral and physical depression. The latter phase is associated with colorful visual hallucinations, without loss of consciousness. Peyote contains alkaloids, especially mezcaline. The speaker injected mezcaline sulfate in a group of animals in doses of 1 Gm. of mezcaline for each kilogram of body

weight. The drug induced rare symptoms and killed the animals within an hour. At necropsy, all the organs of the animals were congested. The lung showed zones of emphysema, and intra-alveolar infiltration of round nucleated cells which had a poor content of chromatin. The lumen of the alveoli was diminished but empty. The liver was in a condition of vacuolar degeneration. The kidneys were nephrotic and showed small hemorrhages, especially in the cortex. The adrenals were the seat of a process of steatosis. Another group of animals had the injection of mezcaline sulfate in daily doses of 0.3 Gm. for each kilogram of body weight. The animals died within fourteen to eighteen days with rare symptoms. The anatomic and histopathologic lesions were of the same type, nature and intensity as those which were seen in the animals killed by acute intoxication. However, in the animals which had a mild intoxication, lesions of degeneration prevailed over those of congestion. The blood of the animals with the acute intoxication did not show alterations. The erythrocytes were diminished and there was a certain degree of leukopenia in the animals that had the chronic intoxication.

Society Reunion

At the Società Napoletana di chirurgia, Dr. Tarantino spoke on hydremia and chloridemia in experimental acute intestinal occlusion, in relation to the behavior of the adrenals. He found that interruption of the duodenum is followed by a diminution of the amount of water and chlorides in the blood. If the animals are previously prepared by administration of adrenal extracts or by transplantation of adrenals before the operation, the variations of hydremia and chloridemia are within physiologic figures. The speaker concluded that the diminution of water and chlorides in the blood of patients who suffer from intestinal occlusion is due to functional disorders of the adrenals.

Professor Giliberti reported results of experiments with Gordon's test for malignant lymphogranuloma. The speaker found that the intracerebral inoculation of a suspension of lymph nodes with malignant lymphogranuloma in broth induces in rabbits meningo-encephalitis of the type described by Gordon. The suspension of malignant lymphogranuloma retains the pathogenic power even when it is filtered through a Berkefeld N filter. The filtrate resists for forty-eight hours the irradiations with 5 mg. of radium. The intracerebral inoculation of suspensions of lymph nodes with disease other than malignant lymphogranuloma did not cause meningo-encephalitis of Gordon's type. The speaker said that Gordon's test is of diagnostic value but has no value in clarifying the etiology of malignant lymphogranuloma.

Marriages

ARTHUR LAGRANGE VAN NAME JR., Center Cross, Va., to Miss Grace Alma Cluverious of Little Plymouth in July.

SIDNEY GREY PAGE JR., Richmond, Va., to Miss Maysville Jane Owens of Cumberland, Md., June 24.

JAMES JOSEPH MCSHEA, Norristown, Pa., to Miss Marcella Rose Marie Furey of Coaldale, June 14.

ASA WING POTTS, Philadelphia, to Miss Marian Carl Sharpless of Rosemont, Pa., July 18.

BERTRAM J. BOUQUET to Miss Dorothy Miller, both of Wabasha, Minn., June 7.

WAIT R. GRISWOLD, Indianapolis, to Miss Alene Daugherty of Paoli, Ind., May 14.

JOSEPH F. RICCHIUTI to Miss Kathleen Ryan, both of Mahanoy City, Pa., recently.

BENJAMIN J. MALNEKOFF to Miss E. Patricia Weller, both of Milwaukee, May 28.

JOHN WESLEY PRATT II, Coatesville, Pa., to Miss Charlotte W. Hand, June 3.

DAVID SLUSS to Miss Inez Jeffries, both of Indianapolis, July 1.

Deaths

Harold Levi Rypins * Albany, N. Y.; Harvard Medical School, Boston, 1919; assistant professor of medicine at the Albany Medical College and formerly associate and instructor in medicine; instructor in medicine, University of Minnesota Medical School, Minneapolis, 1920-1923; secretary of the New York State Board of Medical Examiners; past president of the Federation of State Medical Boards of the United States; member of the National Board of Medical Examiners; member of the executive committee of the Advisory Council on Medical Education; executive secretary of the medical grievance committee of the state education department; fellow of the American College of Physicians; on the staff of the Albany Hospital; aged 46; died, August 25, at Atlantic Beach, L. I.

Josiah Shaftesbury Davies * Tacoma, Wash.; University of Nebraska College of Medicine, Omaha, 1903; member of the American Academy of Ophthalmology and Otolaryngology and the Pacific Coast Oto-Ophthalmological Society; fellow of the American College of Surgeons; served during the World War; on the staffs of the Tacoma General Hospital, St. Joseph's Hospital, Pierce County Hospital, Tacoma, and the Mountain View Sanatorium, Lakeview; aged 60; died, July 11, at Steilacoom Lake of coronary thrombosis.

George W. H. Hemmeter * Baltimore; University of Maryland School of Medicine, Baltimore, 1901; health officer of the Western health district of Baltimore; formerly instructor and demonstrator in the physiologic laboratories of the University of Maryland and the Maryland Medical College; at one time professor of physiology at the Woman's Medical College of Baltimore; aged 63; died, July 12, in the Johns Hopkins Hospital of carcinoma of the bladder.

Louis Heitzmann * New York; College of Physicians and Surgeons, Medical Department of Columbia College, New York, 1885; since 1922 emeritus professor of pathology at the New York Medical College and Flower Hospital; professor of bacteriology and pathology at the Fordham University School of Medicine, 1916-1919; member of the American Urological Association; author of "Urinary Analysis and Diagnosis"; aged 75; died, July 9.

Homer Alanson Millard * Minonk, Ill.; Hahnemann Medical College and Hospital, Chicago, 1890; past president and secretary of the Woodford County Medical Society; for many years member of the school board; served during the World War; at various times on the staffs of St. Mary's Hospital, Streator, Mennonite Hospital, Bloomington, and the Brokaw Hospital, Normal; aged 72; died, July 18, of aplastic anemia.

Delos Edward Cornwall * St. Maries, Idaho; Rush Medical College, Chicago, 1907; past president of the Idaho State Medical Association; president of the Pacific Northwest Medical Association; formerly member of the state board of medical examiners; district surgeon to the Chicago, Milwaukee, St. Paul and Pacific Railway; aged 56; medical director of St. Maries Hospital, where he died, July 5, of coronary occlusion.

James Alfred Watson * Minneapolis; Manitoba Medical College, Winnipeg, Man., Canada, 1895; member of the American Academy of Ophthalmology and Otolaryngology; past president of the Minnesota Academy of Ophthalmology and Otolaryngology; fellow of the American College of Surgeons; on the staffs of the Asbury and Fairview hospitals; aged 71; died, June 17, of coronary thrombosis.

William Travis Gibb * New York; University of the City of New York Medical Department, 1886; instructor of gynecology at his alma mater, 1889-1898; fellow of the American College of Surgeons; served at various times and in various capacities on the staffs of St. Elizabeth's Hospital, New York City Hospital and the Central Neurological Hospital; aged 76; died, July 6.

Simon A. B. Berglund, Marinette, Wis.; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1906; member of the State Medical Society of Wisconsin; served during the World War; formerly health officer; aged 58; on the staff of the Marinette and Menominee Hospital, where he died, July 2, of acute gangrenous stomatitis.

Sidney Clarence Keller * Newark, N. J.; Columbia University College of Physicians and Surgeons, New York, 1905; member of the American Urological Association; on the staffs of the Beth Israel Hospital, City Hospital, St. James' Hospital and the Newark Memorial Hospital; aged 58; died, July 7, of coronary occlusion.

William Freile * Jersey City, N. J.; Bellevue Hospital Medical College, New York, 1898; fellow of the American College of Surgeons; past president of the Hudson County Medical Society; on the staffs of the Christ Hospital and the Medical Center of New Jersey; aged 65; died, July 3, of congestive heart disease.

George Randolph Fox, New Orleans; Tulane University of Louisiana School of Medicine, New Orleans, 1887; past president and formerly secretary of the Avoyelles Parish Medical Society; at one time mayor of Moreauville; aged 75; died, July 7, at the Touro Infirmary of bronchopneumonia.

Raoul R. Haas, Chicago; Chicago Homeopathic Medical College, 1903; Northwestern University Medical School, Chicago, 1906; staff surgeon to the West Side Hospital and the House of Correction Hospital; aged 59; died, July 21, at Cadillac, Mich., of myocarditis and chronic nephritis.

Alexander J. MacKenzie * Port Huron, Mich.; Detroit College of Medicine, 1904; past president of St. Clair County Medical Society; fellow of the American College of Surgeons; chief of staff of the Port Huron Hospital; aged 61; died, July 19, while on his boat at Killarney, Ont., Canada.

Austin Samuel Johnson * Indianapolis; University of Michigan Medical School, Ann Arbor, 1924; on the staffs of the Methodist, City and William H. Coleman hospitals and the Suemma Coleman Home; served during the World War; aged 42; died, July 1, of coronary thrombosis.

Albert Elmo Jones, Kansas City, Mo.; University Medical College of Kansas City, Mo., 1908; member of the Missouri State Medical Association; served during the World War; aged 53; died, July 16, in the Veterans Administration Facility, North Little Rock, Ark., of coronary occlusion.

Herbert Mann, Richmond, Va.; Medical College of Virginia, Richmond, 1903; veteran of the Spanish-American War; instructor in the practice of surgery, Medical College of Virginia, for the sessions 1905-1909; physician in charge of the Penitentiary Hospital; died, July 7.

Everett Monroe Ellison * Washington University School of Medicine, St. Louis, Mo., 1912; on the visiting staffs of the Washington University hospitals; aged 60; died, July 24, in Mexico, where he had been vacationing.

Edward Henry Flynn, Marquette, Mich.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1881; health officer, 1912-1913; aged 79; formerly on the staff of St. Mary's Hospital, where he died, July 1, of hypostatic pneumonia and arteriosclerosis.

Walter James Kirby, Miami, Fla.; University of Toronto Faculty of Medicine, Toronto, Ont., Canada, 1912; member of the Ohio State Medical Association; served during the World War; aged 60; died, July 10, in the Jackson Memorial Hospital of coronary occlusion.

Palmer Lee Carlton, Covington, Ky.; Louisville (Ky.) Medical College, 1901; member of the Kentucky State Medical Association; on the staffs of the William Booth Memorial Hospital and St. Elizabeth Hospital; aged 57; died, July 13, of coronary thrombosis.

Edward Joseph Moore * Philadelphia; University of Pennsylvania Department of Medicine, Philadelphia, 1899; medical director of the Pennsylvania Mutual Life Insurance Company; aged 64; died, June 9, in the Jefferson Hospital of chronic myocarditis.

Edward Jerome Lavin, Baltimore; Temple University School of Medicine, Philadelphia, 1933; member of the Medical Society of the State of Pennsylvania; resident to the Bon Secours Hospital; aged 36; died, July 14, of coronary sclerosis.

Enoch McLain Causey, Franklinton, La.; Tulane University of Louisiana School of Medicine, New Orleans, 1908; member of the Louisiana State Medical Society; aged 60; died, July 11, in Shreveport of uremia and arteriosclerotic heart disease.

Oliver Joseph La Fontaine * Chaumont, N. Y.; University of the City of New York Medical Department, 1894; was health officer of Chaumont from 1915 to 1936 and since 1923 health officer of Lyme; aged 72; died, June 17.

George J. L. Haumesser, Shumway, Ill.; College of Physicians and Surgeons, Keokuk, Iowa, 1881; at various times president and member of the village board, justice of the peace and county coroner; aged 81; died, July 8, in Alton.

Charles Oliver Gamble, Paris, Texas; Howard University College of Medicine, Washington, D. C., 1906; aged 63; died, July 4, in the Veterans Administration Facility, Hines, Ill., of carcinoma of the head of the pancreas.

Edson B. Hart, Bloomington, Ill.; Northwestern University Medical School, Chicago, 1900; member of the Illinois State Medical Society; on the staff of the Brokaw Hospital, Normal; aged 67; died, July 18, of coronary occlusion.

Frank Weeden Mathewson ♂ New Bedford, Mass.; Boston University School of Medicine, 1914; served during the World War; aged 48; died, July 6, in St. Luke's Hospital of burns received when his clothing caught fire.

Frank Clarence Heffner ♂ Cincinnati; Medical College of Ohio, Cincinnati, 1908; aged 53; at various times on the staffs of the Christ Hospital, General Hospital and the Good Samaritan Hospital, where he died, July 10.

Lyle Bruce Hart, Beckley, W. Va.; Rush Medical College, Chicago, 1936; member of the West Virginia State Medical Association; aged 30; on the staff of the Beckley Hospital, where he died, July 6, of carcinoma.

Haliburton McCoy, Puunene, Hawaii; University of Virginia Department of Medicine, Charlottesville, 1918; member of the Hawaii Territorial Medical Association; served during the World War; aged 49; died, July 2.

Edwin Bayard Fisher, Medicine Hat, Alta., Canada; University of Edinburgh Faculty of Medicine, Scotland, 1892; University of Toronto Faculty of Medicine, 1894; aged 71; died, June 9, of cerebral hemorrhage.

Charles Arthur Lapierre, Minneapolis; M.B., School of Medicine and Surgery of Montreal, Faculty of Medicine of the University of Laval at Montreal, 1890, and M.D., 1892; aged 68; died, June 29, of uremia.

Hiram Kilgore McConnell, Gate City, Va.; Hospital College of Medicine, Louisville, Ky., 1907; member of the Medical Society of Virginia; county coroner; aged 58; died, July 14, in a hospital at Richmond.

Adoniram Judson Chalkley, Lexington, Mo.; Washington University School of Medicine, St. Louis, 1905; member of the Missouri State Medical Association; aged 61; died, July 3, of chronic encephalitis.

Louis John Ferenczi ♂ Bayonne, N. J.; Dartmouth Medical School, Hanover, N. H., 1913; aged 48; on the staff of the Bayonne Hospital, where he died, July 18, of carotid aneurysm and cerebral atrophy.

Chalmers Alexander Hill ♂ Council Bluffs, Iowa; Northwestern University Medical School, Chicago, 1907; served during the World War; aged 60; died, July 9, of pneumonia and cerebral hemorrhage.

Clarence Hunter Harris, Louisville, Ky.; Louisville Medical College, 1891; past president of the Jefferson County Medical Society; formerly city and county health officer; aged 68; died, July 8.

George William Carter, Alexandria, Va.; University of Maryland School of Medicine, Baltimore, 1878; aged 84; died, July 20, in Jacksonville, Fla., of uremia and hypertrophy of the prostate.

Edward Pierce Lockart, Norway, Mich.; College of Physicians and Surgeons, Medical Department of Columbia College, New York, 1883; health officer; formerly mayor; aged 81; died, July 10.

Robert Sweney Dombaugh, Marion, Ohio; Columbus Medical College, 1891; member of the Ohio State Medical Association; aged 70; died, July 1, of leukemia and acute hepatitis.

John Aloysius Mogenhan ♂ Rochester, N. Y.; University of Buffalo School of Medicine, 1921; on the staff of St. Mary's Hospital; aged 45; died, June 2, of pulmonary tuberculosis.

Frederick Forest Budd, New Haven, Conn.; Yale University School of Medicine, New Haven, 1903; served during the World War; aged 58; died, June 13, of heart disease.

William A. Fankboner ♂ Marion, Ind.; Rush Medical College, Chicago, 1891; aged 78; on the visiting staff of the Marion General Hospital, where he died, July 14, of carcinoma.

Llewellyn Williams Lord ♂ Baltimore; Johns Hopkins University School of Medicine, Baltimore, 1925; aged 38; died, July 4, of illuminating gas poisoning, self administered.

William L. Hammersley, Frankfort, Ind.; Baltimore Medical College, 1898; aged 70; died, July 18, in the Methodist Episcopal Hospital, Indianapolis, of coronary occlusion.

Oscar Batteiger Herbein, Strausstown, Pa.; Jefferson Medical College of Philadelphia, 1896; aged 70; died, June 18, in the Reading (Pa.) Hospital of heart disease.

George Matthew Ferris, Cobourg, Ont., Canada; Trinity Medical College, Toronto, 1894; University of Toronto Faculty of Medicine, 1894; aged 68; died, July 23.

Henry William Stephenson Kemp, Brooklyn; University of Toronto Faculty of Medicine, Toronto, Ont., Canada, 1906; aged 54; died, July 16, in Bradenton, Fla.

Eli Ellis, Brooklyn; New York Medical College and Flower Hospital, New York, 1934; aged 31; died, June 20, in the Manhattan Eye and Ear Hospital, New York.

Wellington Montelle Carrick, Hamilton, Ont., Canada; University of Toronto Faculty of Medicine, 1905; served during the World War; aged 54; died, July 2.

Reuben William Bennett, Gretna, Va.; University College of Medicine, Richmond, 1899; member of the Medical Society of Virginia; aged 63; died, July 13.

Carl Ludwig Ambos ♂ New York; Cornell University Medical College, New York, 1900; on the staff of the Royal Hospital; aged 66; died, July 23.

Charles Herbert Carruthers, Florence, Ont., Canada; Queen's University Faculty of Medicine, Kingston, 1919; aged 43; died, July 4, of heart disease.

Charles Cunningham Campbell, Youngstown, Ohio; Western Pennsylvania Medical College, Pittsburgh, 1896; aged 72; died, July 14, of heart disease.

Isadore Mogil ♂ New York; Fordham University School of Medicine, New York, 1916; on the staff of the Bronx Hospital; aged 49; died, June 15.

Ulysses L. Dearman ♂ Reedy, W. Va.; Kentucky University Medical Department, Louisville, 1906; aged 71; died, July 11, of heart disease.

George Washington Park, Canton, Texas; Vanderbilt University School of Medicine, Nashville, Tenn., 1888; aged 84; died, June 24, of senility.

TREATMENT OF BROMIDE INTOXICATION

To the Editor:—In an otherwise excellent article on bromide intoxication (*THE JOURNAL*, August 5, p. 466) Dr. Gundry fails to mention an important point in treatment. He suggests sodium chloride by mouth or parenterally to replace the bromide in the system but no note is made of gastric aspiration.

Ordinarily the bromides are eliminated by the kidneys, but Otto E. Toenhart (*Wisconsin M. J.* 12:901 [Dec.] 1935) points out that hydrobromic acid is secreted by the stomach in approximately the same ratio to hydrochloric acid as that of the salts in the blood. By using continuous gastric lavage he prevents reabsorption and materially hastens elimination of the bromides from the body.

During the past two years Dr. E. D. Hoedemaker and I have had occasion to use continuous gastric aspiration in at least twelve cases of bromide psychosis, with gratifying results. The use of sodium chloride alone necessitates from two to six weeks of treatment, but with gastric aspiration the bromides are eliminated in from two to seven days, materially shortening the duration of the intoxication. A continuous drainage with negative pressure bottles is simple and efficacious. Of course, gastric achlorhydria invalidates gastric aspiration and accounted for the failure of this therapy in two of our cases.

FREDERICK LEMERE, M.D., Seattle.

EMBOLISM FOLLOWING KNEE-CHEST POSITION POST PARTUM

To the Editor:—The article in *THE JOURNAL* August 19 on this subject leaves many questions of doubt as to whether the emboli of air were due to air sucked in at the time that the knee-chest posture was assumed.

The explanation of the *modus operandi* of the air getting into the vessels is far from convincing when the condition of the uterine muscle and its interior and the question of physics are considered.

The vagina is a membranous pouch which may be expanded with air with the subject in the knee-chest posture by suction exerted when the abdominal viscera drop toward the chest. The uterus is a heavy, thick walled muscular organ the tendency of which is to contract rather than dilate, and it is questionable whether the weight of the viscera would be sufficient to cause dilatation enough to fill the uterus with air, as it has a tendency to follow the viscera as they drop toward the chest.

It is stated that the uterine sinuses were covered by a clot. This clot would act as a ball valve under pressure and cause closure of the sinuses while the air pressure was maintained. They were naturally found open after removal of the clot in the relaxed dead subject.

It is stated that, when the uterine wall was carefully opened, air escaped from the tissues. How much air pressure would it require to force air from the vagina into the living tissues of the uterine wall? It must be taken into consideration that the least amount of air pressure on the surface of the endometrium would compress it, making it less pervious to air, and the more the pressure the more impervious it would become until the uterine wall gave way.

The simile of the bellows can be used to disprove his explanation of the mechanics of the air entering the sinuses. If one punctures the fabric of the bellows, making a hole the size of the uterine vein, how much air pressure can one get from this hole when the nozzle is left open? If it is assumed that the veins are rigid, noncollapsible tubes from the uterus to the heart, it may be conceived that air would enter them before escaping through the more or less flaccid larger openings of

the cervix and the vulva or the tubes, but the veins collapse and every heart beat increases the vacuum pressure from collapse of the tissues around them to keep them closed. A person will bleed to death from a severed large vein, but there is no air embolism from the heart sucking air into the vein.

It is not stated whether a bacteriologic study was made of the tissues. With manual invasion of the uterine cavity the amount of postpartum debris found, the spongy air-filled condition of the uterine wall and the length of time post partum, a gas bacillus invasion would seem to be suggested and the knee-chest position merely coincidental and misleading.

E. P. HUMMEL, M.D., Sterling, Colo.

A CONVENIENT POSITION FOR SIGMOIDOSCOPY

To the Editor:—For twenty-five years I have employed for patients, and taught my interns to employ, a special position for the use of the sigmoidoscope. While the knee-chest is an acceptable position for men, it is less acceptable for women, especially corpulent ones, and impossible for the sick and weak and for those confined to bed. But I have discovered that many who use the sigmoidoscope do not know of this position, so I am describing it herewith.

The patient lies on the left side across the examining couch or bed, with the buttocks hanging slightly over the edge, the legs drawn up and the back not straight across but at an angle of 10 or 15 degrees to the edge of the bed, so that the shoulders are in advance of the buttocks. It is not a Sims position, for both arms are forward in front of the chest, so that the patient lies squarely on the left shoulder, and the legs are drawn up together on the bed.

The patient is not unduly exposed, is comfortable, and even though sick and weak can stand a prolonged examination when this is necessary.

It might seem that this position would increase the recto-sigmoid angle and so increase the difficulty of inserting the tube into the sigmoid flexure, but in comparative tests with the same patient I have rarely found any difference in the distance to which the tube could be inserted. It makes sigmoidoscopy a very easy process for the patient.

WALTER A. BASTEDO, M.D., New York.

ACETYLCHOLINE IN PAROXYSMAL TACHYCARDIA

To the Editor:—I read with interest the communication from Isaac Starr (*THE JOURNAL*, August 5, p. 527) of the Department of Research Therapeutics, University of Pennsylvania School of Medicine, regarding the use of acetylcholine in paroxysmal attacks of tachycardia in which he states that "one would suppose from reading the answer that acetylcholine would stop attacks of paroxysmal tachycardia when given in doses of from 20 to 30 mg. subcutaneously. . . . This is completely erroneous . . . and there is no valid evidence that it has ever stopped an attack of tachycardia."

I heartily agree with Dr. Starr that administration of the drug subcutaneously has probably never stopped paroxysmal tachycardia. I have, however, observed five cases of paroxysmal tachycardia in which I used the drug intravenously in doses of 0.1 Gm., and in each instance it stopped the paroxysmal tachycardia immediately and this with little if any of the terrific side effects that one gets from mecholyl (flushing, salivation, sweating and hyperperistalsis). In fact, I used it on one patient for three separate attacks of paroxysmal tachycardia and it stopped the attack immediately and abruptly each time.

My personal experience with mecholyl has been quite disappointing in that the side effects were very severe every time.

The effect of the drug on the paroxysmal tachycardia far from approached that of acetylcholine. I observed a patient under the care of another physician who was given mecholyl for paroxysmal tachycardia and the patient promptly died.

I agree with Dr. Starr that "it is essential that physicians distinguish between" acetylcholine and acetyl- β -methylcholine, and particularly that the dangers of mecholyl be thoroughly understood by the physician before he uses it.

KENNETH H. ABBOTT, M.D., Ontario, Calif.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

OLEOTHORAX

To the Editor:—Please discuss the oil treatment in tuberculosis.

R. E. Dupre, M.D., Ville Platte, La.

ANSWER.—It is assumed that what is meant is the use of oil in the pleural cavity. In 1922 Bernou advocated the introduction of oil for pleuropulmonary fistulas of the valve type and in other cases presenting small openings. He believed that massive quantities of antiseptic oil should be employed and named the method of treatment "oleothorax." Since that time a large volume of work has been done on this subject in various parts of the world. In this country, Matson discussed the subject and reported a large number of cases (*Am. Rev. Tuberc.* 25:419 [April] 1932). He presented an elaborate discussion of the indications and a detailed description of the technic of administration. Different preparations of oil have been employed by various workers, such as cajuput oil in liquid petrolatum, olive oil or wesson oil. When cajuput oil is added, it is in a strength varying from 1 per cent to 10 per cent. Many workers today use plain liquid petrolatum or olive oil without cajuput oil.

In more recent times oleothorax has been used in the treatment of tuberculous empyema which develops in patients with pneumothorax. In such cases the empyema cavity is drained as completely as possible by the simple aspiration method and oil is gradually introduced into the pleural cavity. At the first sitting it is well to introduce only a few cubic centimeters to determine whether any reaction occurs. If cajuput oil is being used, one must be extremely cautious by introducing small amounts at first. If no reaction occurs, one may introduce in twenty-four hours a larger amount and gradually increase it until the pleural space is almost filled. In cases in which pus has been forming rather rapidly, one should always leave enough free pleural space so as to avoid pressure developing in the pleural cavity as pus forms. Since the oil is lighter than pus, the latter may be aspirated as necessary by introducing the needle into the most dependent part of the pleural cavity with the patient in the erect position. The oil acts as a mild irritant and results in thickening of the pleura, which often suffices to control the pleural lesions.

Oil is also used in the pleural cavity when the artificial pneumothorax space is being lost by obliterative adhesions, in order to keep the diseased lung collapsed over a longer period than would be possible by the continued introduction of air. In the occasional case an adequate collapse cannot be obtained by the use of air, and the introduction of oil may suffice. Moreover, a more uniform collapse is maintained with oil.

Oil may also be introduced into the pleural cavity when the patient lives in a remote place and cannot report at sufficiently frequent intervals to the office of a physician who administers artificial pneumothorax treatments. Again, there is the patient who is careless, incorrigible or for some other reason will not maintain the necessary treatment schedule to insure a continued collapse by the use of air. Once a good collapse is instituted, one is justified in gradually filling the pleural space with oil in order that the collapse may be maintained. This not only serves as an aid to the patient but often prevents such persons from infecting others with tubercle bacilli.

For patients receiving artificial pneumothorax whose mediastinum is so labile that it shifts far to the opposite side and thus a good collapse of the diseased area cannot be obtained, one

can stabilize the mediastinum by introducing a few cubic centimeters of oil into the pneumothorax space and have the patient lie on the opposite side. The oil will gravitate to the region of the mediastinum and may result in enough irritation to fix the mediastinum.

The only advantage of substituting oil for air in uncomplicated artificial pneumothorax is that the patient does not need to report for refills. In fact, an observation by the physician every two or three months suffices. If pressure develops, a small amount of oil may be removed, or in some cases it may be necessary to add oil occasionally. The duration of oleothorax therapy depends much on the condition at the time it is instituted and the condition of the patient from time to time. If large pulmonary cavities are present when the treatment is begun, the oil may be left in the pleural space indefinitely. If the disease is less extensive, the oil treatment may be discontinued at approximately the same time as one would end artificial pneumothorax treatment. If it was induced for empyema, it may be discontinued when one is reasonably certain that this condition is well controlled.

There are certain disadvantages about the use of oil in the pleural cavity, one of which is that perforations may result either through the chest wall to the surface or into a ramification of a bronchus. Perforations into ramifications of bronchi are not uncommon in ordinary artificial pneumothorax work. They result in bronchopleural fistulas, which may lead to empyema of mixed infection. Therefore it is difficult to state with certainty whether oil in the pleural cavity actually causes this condition. Another disadvantage of oil is that it results in so much thickening of the pleura that it may be impossible for the lung to reexpand after the oil has been removed. A few years ago there was much enthusiasm among physicians for the use of oil in the pleural cavity. More recently, because of greater knowledge of the subject, particularly with reference to the disadvantages, a smaller number of patients are being treated in this manner.

FEVER OF UNKNOWN ORIGIN

To the Editor:—A man aged 30 has irregular attacks of chills and fever that have lasted for three weeks. The temperature is not constant each day, sometimes going to 103 F., sometimes to 99.5; some days there is no fever. His previous history shows that in 1918, while in Mobile, Ala., he had an attack of fever during August while staying in the country and swimming every day in a creek. The fever was high for four days, so high that he was delirious. There were no chills or paroxysmal fever. This fever was experienced the following year under the same conditions but not thereafter, since the family moved to Iowa. In 1931, following a cold five hour ride in the rumble seat of a car one night during which time the man chilled severely, he came down twenty-four hours later with five days of daily paroxysms of chills and fever in the afternoon. At this time the chills were severe for twenty minutes. Then the temperature rose to 104 F. for from two to four hours. Smears for malaria were done during the period of fever; no parasites were found but quinine was given with relief. No subsequent quinine therapy was given following five 20 grain (1.3 Gm.) doses. Later (1932) a careful search for malaria was made of the blood. In 1936 he tells me that he took a course of atabrine at the advice of a friend. What types of fevers infest the coast region that might have caused these childhood fevers? Do any of these become chronic? Is it possible that the fever in 1931 was malaria when the man went home for a visit to Iowa from Tennessee? The five hour night ride was from central Indiana to Nashville, Tenn., and the patient denies any mosquito bites. Is the incubation period for malaria ever twenty-four hours? Would a septic tuberculous extrapulmonary abscess cause the present condition of fever? He has lost 40 pounds (18 Kg.) and the Mantoux reaction is ++ +. I realize that this information is much abridged, but I will appreciate it if you can help me with these questions and add any suggestions.

M.D., California.

ANSWER.—There is no febrile disease that is peculiar to the southern coastal region of this country. It is true that malaria is more common in the southern part of the United States, but owing to improved methods and greater speed of transportation the northern part of this country is rapidly becoming better acquainted with the so-called tropical diseases. Short bouts of fever of undetermined origin are relatively common in children. As a result of swimming in polluted water, throat and ear infections are the most common causes for such fevers.

If this patient had malaria in 1931 it was not the result of inoculation during the preceding twenty-four hours. This does not eliminate the possibility of malaria. He may have been inoculated with the malarial parasite at some previous time and the clinical symptoms appeared coincidentally with the automobile trip only by chance.

An intelligent guess as to the diagnosis cannot be hazarded in this case because of the paucity of information. This is a 30 year old man who has had fever with chills for the past three weeks, has lost 40 pounds and has a positive Mantoux reaction. Extrapulmonary tuberculosis (and pulmonary tuberculosis) is a possibility but cannot be decided on the evidence of

a positive Mantoux reaction. The problem is one of determining the cause of a long continued fever. Since no physical observations or laboratory reports are given, the field is a rather large one.

A study of the blood is indicated. Leukemia, infectious mononucleosis or some other blood disease is a possibility. Blood cultures and other observations should be made to settle the question of subacute bacterial endocarditis. Undulant fever should be eliminated. Atypical typhoid is a remote possibility. Abdominal Hodgkin's disease sometimes runs such a course. These conditions may be present with a minimum of outward physical signs, and there are a host of others that might be indicated by any of a number of physical signs.

For references to extrapulmonary tuberculosis, the correspondent is referred to a number of textbooks, all of which contain excellent bibliographies. Among such books are:

Goldberg, Benjamin: *Clinical Tuberculosis*, Philadelphia, F. A. Davis Company, 1935.
Pottinger, F. M.: *Tuberculosis in the Child and in the Adult*, St. Louis, C. V. Mosby Company, 1934.
Fishberg, Maurice: *Pulmonary Tuberculosis*, Philadelphia, Lea & Febiger, 1932.

CORONARY DISEASE AND ALTITUDE

To the Editor:—Please inform me as to the advisability of allowing a man aged 50, who had a moderate attack of coronary thrombosis eighteen months ago, to take his vacation at Lake George, N. Y. The patient is able to carry on his dental practice. He has never had signs of circulatory failure, is free from anginal pains and is apparently in good health, with a pulse rate of from 70 to 80 a minute. The blood pressure is 110-120 systolic, 80-85 diastolic. Is there any scientific evidence that persons with moderate coronary sclerosis must remain at sea level?

Julius Cogan, M.D., Brooklyn.

ANSWER.—There is no reason why this patient should not take his vacation at any moderate altitude, especially since he is free from symptoms. Altitudes up to 10,000 or 12,000 feet are safe for persons who have had coronary disease including thrombosis provided there are no symptoms at the time, and, even if there are symptoms, on condition that these persons avoid climbing steep grades such as are common at higher altitudes. Many persons feel better in the clear air of hills at from 1,000 to 2,000 feet than they do in the moist air at sea level, whether there is heart disease or not. The heart disease and heart symptoms of such a person may actually be benefited by such a change, since the altitude in itself has no deleterious effect.

ANILINE DERMATITIS

To the Editor:—The company for which I am plant physician is using a small percentage of para-nitrosodimethylaniline as an accelerator in one of its rubber compounds. I am unable to discover in any books available to me whether or not this aniline derivative is toxic and if so in what percentages it is dangerous. I found this statement in "Chemistry and Technology of Rubber" (Davis, C. C., and Blake, J. T. Reinhold, 1937, p. 875): "During vulcanization, para-nitrosodimethylaniline yields some para-aminodimethylaniline. . . ." I have further learned that the actual chemical process of an accelerator in rubber vulcanization is not known, although it is supposed that there is an activation of the chemistry involving the sulfur radical in the process. While all workmen handling this material have been closely watched, we have found no evidence of aniline toxicity. However, we have noted a yellow discoloration of the skin of the hands which is not removed by soap and water. I should appreciate your assistance in sending me references that I can find in the Cleveland medical library or, if possible, reprints covering this subject.

M.D., Ohio.

ANSWER.—Para-nitrosodimethylaniline may be accepted as a rubber accelerator which has produced dermatitis among exposed rubber workers. This substance is not a new addition to the long list of accelerators but was used at least as early as 1917. Prosser White (Occupational Affections of the Skin, ed. 4, London, H. K. Lewis & Co., Ltd., 1934, p. 253) states: "Severe cutaneous inflammations, increasing in severity according to length of exposure, are due to para-nitrosodimethylaniline. This substance often goes by the name of 'accelerine.'" Shepard and Krall (Poisons in the Rubber Industry, *J. Indust. Hyg.* 2:33 [May] 1920) note that in 1917 the rubber section of the American Chemical Society requested a committee on organic accelerators to investigate the toxic properties of a group of such substances, including para-nitrosodimethylaniline. This report is published in the *Journal of Industrial and Engineering Chemistry* (10:865, 1918) and in the *India Rubber World* (59:82, 1918). Prosser White cites Bridge in connection with para-aminodimethylaniline and states: "This has caused dermatitis in hardeners and steamers in a 'hard felt sheeting' department." In 1927 Quinby (*J. Indust. Hyg.* 8:102) refers to para-nitrosodimethylaniline as a source of severe inflammation of the skin. Schwartz (Pub. Health Bull. 215, October 1934) reviews the literature referable to dermatitis in the rubber industry and

includes several references to para-nitrosodimethylaniline. He mentions the work of Healy (*Nat. Safety Council Tr.* 2:783, 1929) and Davis (*Rubber Age* 25:199, 1929). A later article (*Rubber Age* 29:367, 1931) furnishes the best information now available. He states: "Para-nitrosodimethylaniline is a very toxic substance. During its incorporation with rubber it comes in contact with hydrogen sulfide and is reduced to paraminodimethylaniline, giving the following toxic radicals: amido, nitroso and aniline. Chief effects are dermatitis, stubborn sores, nose and throat irritation, gastrointestinal irritation, nephritis, toxic anemia with blood cell pathology. However, the material is used in such small quantities that there is no danger if men wear gloves to prevent the material from coming in contact with the skin. The material is usually used in a paste form."

FATIGUE, AMINOACETIC ACID AND GELATIN

To the Editor:—1. A married woman, aged 26, has had no illness except a mild case of influenza in February of this year. The urine is normal; the white and red blood cell count is within normal limits, with no abnormal cells but with hemoglobin for the past five months ranging between 70 and 76 per cent even though she has been taking some iron. The tuberculin reaction is negative and she complains of slight fatigue and an occasional temperature of as much as 99.4 F., but this is not constant. Do you suggest any treatment; if so, what? Do you think that the hemoglobin is too low? Any suggestions with regard to treatment or therapy will be appreciated by me. 2. In *The Journal* July 8 I read with a great deal of interest the article on Knox Sparkling Gelatine, put up in Johnstown, N. Y. For some time I have been advising the taking of the contents of from two to four of the small envelopes that come in a package stirred into a glass of cool water. This amount each day was advised for from two to four weeks for patients showing fatigue. I note that this product is not now acceptable but I know that it had been on the accepted list. Do you think that the product could produce any harm or have any bad effects on the patient if it is merely stirred into the water and drunk that way? Even though it does not help fatigue, do you consider it harmful in any way to the patient? I know that aminoacetic acid with vitamin B₁ is recommended in fatigue; am I right in this? If so, what dosage and what preparation would you advise? Is it harmless?

M.D., Alabama.

ANSWER.—1. It would seem that the patient described is enjoying fairly good health. A hemoglobin content of from 70 to 75 per cent is not usually considered entirely satisfactory and may be enough to account for the occasional fatigue. Unless there is some cause for the anemia apart from iron deficiency, the low hemoglobin may be overcome by liberal iron therapy. An occasional temperature of 99.4 F. may or may not be significant. It is less significant in a person who is up and about than in one who is kept at rest. Such temperatures are found to be normal for certain persons. A careful search should reveal the significance of the elevation of temperature in this case.

2. The amino acids have long been used in certain instances of muscular weakness. Probably the most potent of these is aminoacetic acid, which forms the basis of numerous preparations. In certain types of myasthenia the use of one of these preparations has been thought to be helpful. The dose is relatively high and the preparations are rather expensive. It has been urged that gelatin may have a beneficial effect in muscular fatigue and muscular weakness but insufficient evidence bolsters up these claims. The critical observer is far from convinced. While no harm can come from the moderate use of gelatin, neither can any startling results be expected. The same may be said for vitamin B₁ and the other amino acid preparations. It would seem wiser to attempt to fathom the cause of the fatigue than to present the patient with crutches in the way of amino acid preparations.

TREATMENT OF GRANULOMA VENEREUM

To the Editor:—I am anxious to know a good treatment for granuloma inguinale. Can you give me some information on satisfactory treatment for this disease?

W. M. Cason, M.D., Sandersville, Ga.

ANSWER.—Granuloma inguinale, better known as granuloma venereum, is caused by the Donovan bodies. Their true nature is not yet known. This disease is seen almost entirely in Negroes and is most rebellious to treatment. Unless therapy is kept up until long after the clinical manifestations have cleared up there is a tendency for it to relapse. One of the first requisites with the disease is prophylaxis and prevention of spread to others. Cleanliness is also in order, since there is often a secondary Vincent's infection superimposed on the granuloma venereum. For example, potassium permanganate 1:4,000 in the form of sitz baths twice a day is useful. Soap and water are also indicated. Preparations of antimony seem to give the best results in the treatment of this disease, par-

ticularly fuadin. Treatment is given by intramuscular injection, starting with a dose of 1.5 cc. the first day, 3.5 cc. the second day and 5 cc. the third day, changing buttocks at each injection. After the first three doses are given five or six additional doses may be administered two or three days apart. After a total of some 40 cc. of the fuadin has been given, it is well to discontinue treatment for a week or so. The urine should be watched closely for evidence of irritation of the kidneys. If there is no irritation, a succeeding series of injections may be employed. It is necessary, however, that therapy be used after all clinical manifestations have disappeared, for in many of these cases biopsy made from the affected areas, even after they are apparently well, may still show the Donovan bodies in the tissue. As a rule no effect other than occasional irritation of the kidneys is noted with this preparation. Now and then there may be some headache or nausea, rarely some complaint of joint pain, transitory in character. Permanent cure of granuloma venereum requires expert care and much patience on the part of both patient and physician.

CHILLS AND FEVER

To the Editor:—I was called recently to see a man aged 35 who is a stationary engineer. The symptoms of which he complained extend back over a period of fourteen years. During these years he has spent a lot of money going through clinics, but the answer has always been that he has no organic disease. The spells of which he complains come out of a clear sky. There is usually a chill, sometimes severe, lasting from three to four hours. He has a slight headache at these times. The temperature is always up to 101 F., sometimes 101.4. The pulse is accelerated to 120 or 130. The legs ache. These spells last about twenty-four hours, after which he is apparently back to normal again. With these spells he has what he describes as acute indigestion, with symptoms more or less severe. The spells are gradually getting worse. There is a bowel movement every day but there is a tendency to constipation. He takes sodium bicarbonate or the "patent medicines" that are on the market for this purpose. I have not had an opportunity of doing any laboratory work on this patient. I suppose that all the laboratory work indicated has been done in the clinics he has visited. Besides chronic cholecystitis, what other possibilities should be considered?

M.D., Minnesota.

ANSWER.—It would, of course, be necessary to obtain the complete reports of the examinations in the various clinics visited by the patient and to learn whether the patient has ever been accurately studied during one of his "spells." Nothing is said as to what the patient means by "acute indigestion." An illness lasting only twenty-four hours is seldom observed by a physician in time to make the necessary observations. If the studies made elsewhere have been complete and have thus far not revealed any organic disease, a different line of diagnostic attack must be pursued. One is at a loss to suggest what infection could cause illness, such as that described, over a period of fourteen years without disappearing in time or getting much worse.

The severe chill, relatively high fever, intestinal symptoms and suddenness of the onset and recovery suggest an allergic type of reaction rather than the so-called psychogenic fever. A careful study should be made to test the patient for possible sensitivity to many substances with which he may come in contact in his work, diet, pastime and so on. Does the illness usually start at one time of the day or another? Are there any psychic or other underlying factors in the case? Not until such studies have been made can a decision be reached. It is unlikely that the patient has chronic cholecystitis.

TURBINATE SHRINKING

To the Editor:—Please let me know what success has been had with turbinate shrinkage with sclerosing solutions and what solution seems to give best results.

J. B. H. Waring, M. D., Wilmington, Ohio.

ANSWER.—Various solutions have been used in the nose with the idea of shrinking the turbinates. Among these have been a 20 per cent solution of sodium chloride, a 50 per cent solution of dextrose and a 20 per cent solution of sodium salicylate. Quinine hydrochloride and ethyl carbamate have been used as well as quinine lactate. Lafayette P. Monson (Treatment of the Hypertrophied Inferior Turbinate by Use of Sclerosing Solutions, *Arch. Otolaryng.* 22:96 [July] 1935) has used the latter and claims to get good results. Others, among them H. H. Vail (Treatment of Hay Fever by Nasal Injections of Alcohol, *ibid.* 18:651 [Nov.] 1933), have used alcohol in various concentrations and have reported a similarly beneficial outcome.

A 5 per cent sodium psyllate solution has, in addition, recently been recommended, one claimed advantage for it being that no anesthetic is required as is the case with alcohol, in which procaine is frequently added to the mixture.

It is difficult to say which solution gives the best results. None of them work perfectly and all have their advocates. The important thing is that the medications used be safe and not produce deleterious reactions, such as undue pain, swelling and sloughing. For this reason a 40 to 60 per cent ethyl alcohol solution is probably as good as any.

STERILIZATION OF DISHES

To the Editor:—Can you give me any information as to the sterilization efficiency for dishes, drinking glasses and silverware of F. D. A. phenol coefficient 2.25, formula K. P. 100, a bactericidal detergent made by the Pioneer Manufacturing Company, Cleveland? If not, can you tell me what product you recommend for sterilizing a patient's dishes other than by boiling?

Jeanette F. Thomas, Hospital Superintendent, North Conway, N. H.

ANSWER.—Sterilization of utensils by chemical agents involves not only employment of solutions that are actually germicidal but also adequate contact between germicide and bacteria. The latter is the more difficult phase of the problem. Literally countless chemical agents have been recommended and are on the market that under ideal laboratory conditions are able to kill suspensions of test bacteria as well as, or better than, a standard solution of phenol. But it does not follow that similar results are obtained on contaminated tableware, where many of the pathogenic organisms are protected by insoluble materials such as grease, the remains of food, coagulum and dried mucus. Attempts to solve the problem by adding detergents to bactericidal solutions have not, on the whole, proved successful. Washing the dishes clean before applying the germicide is not feasible, since that involves handling the contaminated objects and almost uncontrollable dissemination of the very organisms that it is desired to destroy.

The "bactericidal detergent" referred to in the inquiry is "K. P." (Kitchen Police), said by the manufacturers to be a derivative of their product "K. O." (Kills Odor) plus a detergent powder. The chemical nature of these products is not divulged. "K. O." in 1:192 solution is alleged to have a phenol coefficient of 2.25, but in advertising emphasis is laid chiefly on its deodorant properties. No acceptable evidence that "K. P." is an effective disinfectant for contaminated utensils has been found.

Sterilization of contaminated dishes, drinking glasses and silverware by boiling water or live steam is simple, rapid, inexpensive and absolutely certain. That is more than can be said for any method of chemical disinfection known at present.

SUDDEN LOSS OF BLOOD

To the Editor:—Do you think it possible for a man aged 43, 5 feet 7 inches (170 cm.) tall, weighing 175 pounds (79.4 Kg.), to lose 3 quarts of blood within a period of three or four hours and survive? Is it probable that blood taken from his ear twenty-four hours later would show only a small decrease in red cells?

M.D., Texas.

ANSWER.—A definite reply to the question is difficult without more specific information about the circumstances of the loss as well as the state of health of the patient. Such a man as described would probably have about 7 quarts of blood. It is usually considered that a man cannot survive loss of more than 40 per cent of the total blood volume without prompt treatment. Survival in the case cited is not impossible but it is extremely improbable. The blood picture at twenty-four hours would depend on the method of loss, the rate of loss, the water intake and output and the sensitivity of the vasomotor system, all of which are unpredictable. General experience, however, would justify the prediction that a definite reduction in the red blood cell count would persist for several days or even weeks.

SULFANILAMIDE AND IRON THERAPY

To the Editor:—A patient with an acute case of trachoma of the eyes is receiving copper sulfate from 1.5 to 2 per cent in glycerin locally in the eyes and one-third grain (0.02 Gm.) of sulfanilamide per pound of body weight with equal amounts of sodium bicarbonate daily. The last laboratory report showed that she had 3,480,000 red blood cells and a hemoglobin content of 74 per cent. At this time the question came up of giving her some iron preparation. Would there be any contraindication to such iron therapy concurrently with sulfanilamide medication? I have been unable to find anything in the literature. I wonder whether you could advise me?

Max W. Jacobs, M.D., St. Louis.

ANSWER.—Concurrent iron therapy in a patient who is receiving sulfanilamide is not contraindicated if the patient is anemic. As a general rule anemias do not respond well to iron therapy until the underlying infection is brought under control by sulfanilamide therapy.

Medical Examinations and Licensure

COMING EXAMINATIONS

STATE AND TERRITORIAL BOARDS

Examinations of state and territorial boards were published in THE JOURNAL, September 16, page 1154.

SPECIAL BOARDS

AMERICAN BOARD OF Board of Surgery. Ora Paul M. Wood, 745 Fifth Oct. 14-15. Sec., Dr. Philadelphia, Nov. 3-4. Sec., Dr. C. Guy Lane, 416 Marlboro St., Boston. AMERICAN BOARD OF DERMATOLOGY AND SYPHILOLOGY: Oral. Philadelphia, Nov. 3-4. Sec., Dr. C. Guy Lane, 416 Marlboro St., Boston. AMERICAN BOARD OF INTERNAL MEDICINE: Written. Various sections of the United States, Feb. 19. Formal application must be received on or before Jan. 1. Sec., Dr. William S. Middleton, 1301 University Ave., Madison, Wis. AMERICAN BOARD OF OBSTETRICS AND GYNECOLOGY: Written examination and review of case histories (Part I) for Group B candidates will be held in various cities of the United States and Canada, Jan. 6. Applications for admission to Group B, Part I, examinations must be on file not later than Oct. 4. General oral and pathological examinations (Part II) for all candidates (Groups A and B) will be conducted in Atlantic City, N. J., June 8-11. Applications for admission to Group A, Part II examinations must be on file not later than March 15. Sec., Dr. Paul Titus, 1015 Highland Bldg., Pittsburgh (6). AMERICAN BOARD OF OPHTHALMOLOGY: Written. Various cities of the United States and Canada, March 9. Oral. New York, June 10. Formal applications must be received before Jan. 1. Sec., Dr. John Green, 6830 Waterman Ave., St. Louis. AMERICAN BOARD OF ORTHOPAEDIC SURGERY: Boston, January. Applications must be filed on or before Nov. 1. Sec., Dr. Fremont A. Chandler, 6 N. Michigan Ave., Chicago. AMERICAN BOARD OF OTOLARYNGOLOGY: Chicago, Oct. 6-7. Sec., Dr. W. P. Wherry, 1500 Medical Arts Bldg., Omaha. AMERICAN BOARD OF PATHOLOGY: Memphis, Nov. 22-23. Sec., Dr. F. W. Hartman, Henry Ford Hospital, Detroit. AMERICAN BOARD OF PEDIATRICS: New York, April 30 and May 1. Kansas City, Mo., preceding the Region III meeting of the American Academy of Pediatrics. Seattle, June 2. Sec., Dr. C. A. Aldrich, 723 Elm St., Winnetka, Ill. AMERICAN BOARD OF PSYCHIATRY AND NEUROLOGY: New York, December. Sec., Dr. Walter Freeman, 1028 Connecticut Ave. N.W., Washington, D. C. AMERICAN BOARD OF RADIOLOGY: Atlanta, Ga., Dec. 9-11. Sec., Dr. Byrl R. Kirklm, 102-110 Second Avenue S.W., Rochester, Minnesota. AMERICAN BOARD OF UROLOGY: Chicago, Feb. 9-11. (The only examination session to be held in 1940.) Case reports must be submitted not later than November 9. Sec., Dr. Gilbert J. Thomas, 1009 Nicollet Ave., Minneapolis.

Florida June Examination

Dr. William M. Rowlett, secretary, State Board of Medical Examiners of Florida, reports the examination held at Jacksonville, June 19-20, 1939. One hundred and sixty-seven candidates were examined, 143 of whom passed and twenty-four failed. The following schools were represented:

School	PASSED	Year Grad.	Number Passed
University of Arkansas School of Medicine.....	(1938, 3)		3
College of Medical Evangelists.....	(1937)		1
George Washington University School of Medicine.....	(1935), (1939)		2
Howard University College of Medicine.....	(1933)		1
Atlanta Medical College.....	(1914)		1

Nebraska June Examination

Mrs. Clark Perkins, director, Bureau of Examining Boards, reports the written examination held at Omaha, June 8-9, 1939. Seventy-seven candidates were examined, all of whom passed. The following schools were represented:

School	PASSED	Year Grad.	Number Passed
Creighton University School of Medicine.....	(1938, 2), (1939, 14)		16
University of Nebraska College of Medicine.....	(1937), (1938, 3), (1939, 57)		61

Six physicians were licensed by reciprocity and one physician was licensed by endorsement from January 30 through June 5. The following schools were represented:

School	LICENSED BY RECIPROCITY	Year Grad.	Reciprocity with
University of Colorado School of Medicine.....	(1936)		Colorado
Northwestern University Medical School.....	(1929)		Kansas,
(1935) Iowa			
State University of Iowa College of Medicine.....	(1936)		Iowa
University of Kansas School of Medicine.....	(1937)		Kansas

LICENSED BY ENDORSEMENT			
School	Year Grad.	Endorsement of	
University of Nebraska College of Medicine.....	(1932)	N. B. M. Ex.	

South Dakota July Report

Dr. G. J. Van Heuvelen, director, Medical Licensure, reports the written examination held by the South Dakota State Board of Medical Examiners at Rapid City, July 18-19, 1939. The examination covered thirteen subjects and included 100 questions. An average of 75 per cent was required to pass. Eleven candidates were examined, all of whom passed. One physician was licensed by reciprocity. The following schools were represented:

School	PASSED	Year Grad.	Per Cent
Loyola University School of Medicine.....	(1926)		83.8
Northwestern University Medical School.....	(1938) 89.6,	(1939)	85.6
Rush Medical College.....	(1934) 80.4,	(1937)	90.3
University of Minnesota Medical School.....	(1938) 81.7,	(1939)	89.6
Creighton University School of Medicine.....	(1935) 83.7,	(1938)	82.5
University of Nebraska College of Medicine.....	(1938)		83.4
Marquette University School of Medicine.....	(1939)		84.8
LICENSED BY RECIPROCITY			
School	Year Grad.	Reciprocity with	
State University of Iowa College of Medicine.....	(1928)	Montana	

* This applicant has received the M.B. degree and will receive the M.D. degree on completion of internship.

Book Notices

Marihuana, America's New Drug Problem: A Sociologic Question with Its Basic Explanation Dependent on Biologic and Medical Principles. By Robert P. Walton, Professor of Pharmacology, School of Medicine, University of Mississippi, University. With a foreword by E. M. K. Gelling, Professor of Pharmacology, University of Chicago, and a Chapter by Frank R. Gomila, Commissioner of Public Safety, New Orleans, and M. C. Gomila Lambou, Assistant City Chemist, Cloth. Price, \$3. Pp. 223, with 17 illustrations. Philadelphia, Chicago, New York, Montreal & London: J. B. Lippincott Company, 1938.

This book has served to bring together a large body of information on Indian hemp. Much of the material represents a concise interpretation of the present bibliography on the subject. The author reviews the history of the misuse of hashish and concludes that this "vice" has flourished conspicuously in many countries for the last thousand years. He points out that during the fourteenth century officials were making desperate but unsuccessful efforts to eradicate the practice and that later in the nineteenth century Napoleon's generals used forceful methods in an attempt to curb the vice, which was then considered pernicious. The author believes that these restrictions were temporarily successful and that the practice has continued at the present time with no particular prospect of being exterminated. The history of the misuse of hemp in other countries tends to support the view that the American misuse will not be speedily eradicated. The book reviews the distribution of the hashish vice from the world standpoint, and the present status of its misuse in the United States is also considered. The latter represents largely a compilation of articles from the public press. The authors of that section, however, mention that serious minded observers have found it difficult to express the real extent and gravity of the situation and that there has been no especially systematic attempt to estimate the current distribution of the misuse of marihuana. Newspaper reporters and magazine feature writers have probably given more active attention to the matter of dramatizing the situation. Although a serious attempt is made to review the present status of knowledge with reference to its distribution in the United States, nevertheless much of the information is not based on scientific inquiry as to where, when and under what conditions such a vice flourishes. The source of the plant is discussed; the technic of its misuse; the experiences of its use are described; the acute and chronic effects are mentioned; the therapeutic application of cannabis is discussed, and the pharmacologic and chemical action are also briefly reviewed, together with a determination of physiologic activity. The book contains a complete nomenclature of words equivalent for the hemp plant or the crude drug as they are applied to different parts of the world, and also a rather exhaustive bibliography on the subject. On the whole, the book represents a rather satisfying clerical compilation but adds nothing especially new in the field. It will serve as a valuable reference.

La coca: Estudio medico-social de la gran toxicomania peruana. Por Luis N. Saenz. Paper. Pp. 235. Lima: Imp. de la E. de la G. C. y P., 1938.

The author presents a thorough study concerning the uses, abuses and effects of the coca leaf and its derivatives among the population of Peru. The book is divided into three parts. Part I deals with the drug itself. The author describes in detail the role of coca leaves in the routine life of the Peruvian native from historical, medicinal, occupational and economic aspects. The relationship of the coca leaf and its derivatives to cocaine addiction is explained. He presents fairly the various important concepts concerning addiction to the coca leaf and the drugs derived from it. Part II deals chiefly with the addiction through the coca leaf and the effect that it has on the individual physically and mentally and, in a broad aspect, socially. Interesting results of studies concerning habit and abstinence in the coca leaf user and also studies of the action of the drug are presented. Part III concerns recommendations for the treatment of coca leaf users in Peru. The author advocates social and legislative measures regarding the undesirable effects of drug addiction. For this purpose he employs the aid of the educational system, philanthropic enterprises, patriotic citizens and the medical and legal professions. He advocates

the daily use of radio programs for the dispersing of educational propaganda concerning the ravages of addiction to drugs, particularly the coca leaf. He feels that drug addiction is a problem of national concern and advocates that the state subsidize agriculture so that employers may pay for services rendered entirely in money instead of part money and part coca leaf as is the custom in many districts in the mountain regions of Peru. It is believed that in this book Saenz has presented the problem of addiction to the use of the coca leaf in Peru in its true light, i. e. one of sociological, medical and economic importance. His analysis of the situation is thorough and his remedial suggestions are meritorious and of international interest.

Anemia in Practice: Pernicious Anemia. By William P. Murphy, A.B., M.D., Associate in Medicine, Harvard Medical School, Boston. Cloth. Price, \$5. Pp. 344, with 46 illustrations. Philadelphia & London: W. B. Saunders Company, 1939.

This volume represents a detailed discussion of the clinical investigations of pernicious anemia in which the author has participated during the past fifteen years. The importance of treatment in the presence of complications, particularly the neurologic, is stressed and well presented. A briefer and somewhat less comprehensive presentation of certain of the other anemic states is included, apparently for the sake of completeness. The use of liver extract in the treatment of the hemolytic anemias would seem to be somewhat uncritically and over-enthusiastically advocated in the light of the published experience from other clinics and on the basis of the known difference in the pathologic changes in the bone marrow in pernicious anemia (megaloblastic hyperplasia) and in hemolytic jaundice (normoblastic hyperplasia) and of the knowledge of the point in the erythrocyte maturation cycle at which the erythrocyte maturation factor is effective. The treatise has been written by the author that "the facts may be conveniently available for practical application" and that they may "be read with pleasure by the physician, and benefit not only him but his patient as well." The last two chapters deal with the more essential routine laboratory procedures in hematologic diagnosis and a brief reference to blood transfusion.

Die Zuckerkrankheit: Leitfaden für Studierende und Ärzte. Von Prof. Dr. Ferdinand Bertram, leitender Arzt der II. medizinischen Abteilung des allgemeinen Krankenhauses Darmbeck, Hamburg. Second edition. Paper. Price, 6 marks. Pp. 123, with 17 illustrations. Leipzig: Georg Thieme, 1939.

Bertram's book has been revised five years after its first appearance to include the aspects of diabetes which have changed in the interval, especially those which deal with the pathogenesis of the disease and certain questions in therapy. He emphasizes the importance of the influence of the anterior pituitary lobe as an organ effective in the regulation of blood sugar and reviews the investigations of Houssay, Young and Best. The experiments of these authors are believed to confirm the conception that a hormone antagonistic to insulin is produced by the anterior pituitary lobe.

In the section on clinical diabetes Bertram defines diabetes as a chronic disease of the total neuro-endocrine apparatus with a hypofunction of the pancreas in the foreground. A disturbance in the anterior pituitary lobe is etiologically responsible for some cases of diabetes, if not for all. In the etiology he shares the unitarian point of view, already represented by Naunyn, that all cases of diabetes have a constitutional hereditary background, a congenital minus variation of the endocrine system. Bertram considers certain exogenic factors, especially nutritional changes, responsible for the great increase of diabetes observed in all civilized countries. He calls diabetes an outspoken disease of civilization. The chapter dealing with the increase of diabetes is especially worth while. In a classification of the severity of diabetes he distinguishes mild cases as being those in which with sufficient diet (at least 150 Gm. of carbohydrate) and without insulin ketosis does not develop, moderately severe cases as those in which adequate diet alone does not control ketosis but insulin is required, and severe cases as those in which, in spite of adequate diet and insulin, ketosis is present.

In the section dealing with complications of diabetes, neuritis is explained on the basis of a hypovitaminosis due to a deficiency of vitamin B₁. Diabetic neuritis, however, is believed to be

very resistant to B₁ therapy. He considers that the high incidence of vascular disease is to be expected on the basis of the present increase of longevity in diabetes. According to Bertram there is no doubt that the cause of the frequent incidence of vascular disease in diabetes is the excess of fat in the diet.

In a discussion of pregnancy in diabetes he emphasizes the high mortality of children of diabetic mothers and states that in his experience the fetal mortality was 50 per cent. He attributes the gigantism in the child to lack of control of maternal diabetes and believes that it can be prevented by sufficient control of hyperglycemia. He believes that the blood sugar of the mother should be kept low in the last month of pregnancy. He recommends cesarean section in suspected eclampsia or in any instance of deterioration of the metabolic situation. He divides coma into three classes, dyspneic, cardiovascular and renal. The section on pseudo diabetic peritonitis is very good.

The second part of the book is concerned with the treatment of the disease. Bertram represents the modern school using relatively high carbohydrate diets. His principles are that the diet should be rich in carbohydrate and poor in fat and should contain a moderate amount of protein. Although the diets are exactly calculated and balanced, he thinks that precise prescriptions are to be avoided. The diabetic patients must not use scales. He does not recommend qualitative analysis of the urine by the patient. The best measure of the management of the diabetes is the subjective well being of the patient. He recommends a simple diet to avoid overnutrition. In his discussion of the insulin management of diabetes, Bertram describes the historical development of protamine, reviewing his own first attempts to increase and prolong the action of insulin by the addition of various proteins. Results with protamine insulin are believed to be good in the majority of cases. He employs one injection in twenty-four hours. Complete failure occurred in only three cases. In severe cases of diabetes he recommends two injections of protamine.

In the treatment of coma he recommends dextrose, which he believes to be more important than insulin. For every 3 Gm. of carbohydrate, 1 unit of insulin is given. In incessant vomiting and impending uremia, large quantities of sodium chloride are given in hypertonic solution (from 20 to 50 cc. of 10 per cent saline solution). In cases of extreme acidosis, alkalis are employed. He uses a 4 per cent solution of sodium bicarbonate. Diabetes in childhood is briefly discussed and he reemphasizes the point that all diabetic children should be treated with insulin. This excellent monograph is highly recommended to all interested in diabetes.

Angina Pectoris: Nerve Pathways, Physiology, Symptomatology, and Treatment. By Heyman R. Miller, M.D., Attending Physician, Sydenham Hospital, New York. Cloth. Price, \$3.25. Pp. 275, with 39 illustrations. Baltimore: William Wood & Company, 1939.

As the author himself asks in the first line of his preface, Why another book on cardiac pain or angina pectoris? His answer is: "There is no dearth of books in this field and yet even after 150 years or more of study of this malady or syndrome the fundamental problems remain unsolved. This volume makes no claim to the solution of these vital questions but is an attempt to restate and to analyze them anew in the light of our present day knowledge. To this end a cardinal prerequisite is a clear understanding of the pathways that initiate, transmit and deliver cardiac pain into consciousness. As a matter of interest, this little volume grew out of an original desire to present a series of carefully drawn anatomical charts of the cardiac innervation and this desire, I believe, has been fulfilled. It was realized, however, that a mere delineation of the pathways with no descriptive text of their known physiology would be intelligible only to the research specialist in this field. To make the drawings available to a larger group, the text was developed to implement the drawings and to include as much of the clinical aspects as was needed for a rather comprehensive presentation of the subject."

These anatomic charts are interesting, helpful, and well done, though a few are so simplified that they seem superfluous. One may especially recommend the study of figures 30 and 31 on pages 96 and 97, which give front and side views of the sympathetic and vagal cardiac innervation, and figures 37 and 38 on

pages 135 and 137, giving the pathways for referred pain for the gallbladder into the cardiac territory and vice versa, the former two summarizing the previous diagrams, and the latter two helping to explain the distribution and reference of pain. In the discussion of the paroxysm of angina pectoris in itself the author emphasizes the possible nervous manifestations: "A paroxysm of angina pectoris, we believe, is an expression of a paroxysmal upheaval of the entire autonomic system with manifestations that are characteristic of each of its divisions, each limb acting as if its central nucleus were set off. We shall call attention especially to the unitary mass action and mutuality of these divisions rather than to their apparent antagonisms." This description, however, is an exaggerated account of the usual attack of angina pectoris. In the first sentence just quoted "is" should better be "may be," since often a paroxysm of angina pectoris has no other manifestations related to it. The most useful parts of the volume are the description of the cardio-aortic nerve connections and the transmission, distribution and simulation of anginal pain, to be found in sections 2 and 3; treatment might to advantage have been omitted, just as many other aspects of angina pectoris have been wisely omitted from this type of book. The diagrams should prove helpful to the student and physician who are not yet familiar with the recent advances in this subject.

Veröffentlichungen aus der Konstitutions- und Wehrpathologie. Herausgegeben von L. Aschoff, W. Ceelen, W. Koch und P. Schürmann. Geleitet von W. Koch. Heft 43. Band X, Heft 1: Über die menschlichen sireniformen Missbildungen. Von Günter Frädrich. Paper. Price, 6 marks. Pp. 84, with 48 illustrations. Jena: Gustav Fischer, 1938.

This small paper-covered monograph is a careful study of a rare congenital fetal malformation, the sireniformen fetus (sympodia, sirenomelia) in which there is a complete or partial fusion of the lower limbs. The term sireniformen, which Ballantyne says is less acceptable than sympodia, refers to a fabulous creature, the siren. The author reports twelve specimens which have been collected over a period of years. He has made a careful study of these monstrosities and has catalogued the various deformities. The whole pelvis is malformed in most of the fetuses. The sacral and coccygeal vertebrae may be defective or excessive in number and the tip of the spinal column may be directed backward, to one side or even upward, which may account for the occasional presence of a chordaform projection in the sacral region. The lower limb represents all degrees between complete fusion of the constituent bones, muscles, vessels and nerves and a simple membranous union of the two outwardly rotated limbs. The bladder is usually absent. One artery is almost always present in the umbilical cord. The author carefully describes the absence or presence of the usual anomalies in his collection. For the most part he agrees with the excellent descriptions of these unusual monstrosities already in the literature. No new theory is advanced for their causation. This monograph will be of interest only to students of teratology.

Two Lifetimes in One: How Never to Be Tired; How to Have Energy to Burn. By Marle Beynon Ray. Cloth. Price, \$1.96. Pp. 311. Indianapolis and New York: Bobbs-Merrill Company, 1938.

This is a popular presentation for those who are none too sure of their own mental capacities. The desire of Americans to become more efficient in their mental lives has resulted in a plethora of books designed to aid them in developing their efficiency and their ability to meet people, to make a favorable impression and to live more wholesome lives and in every conceivable way to make them "successful" citizens. Since, after all, the root of most maladjustment is in childhood and the way the individuals are trained, as well as in their later economic opportunities, clinic help can seldom be supplanted by a book unless it is miraculously therapeutic; and there is nothing about the present volume that makes it worthy of note except that it is highly readable. It contains examples of individuals who have made use of their time in a more efficient manner or who have changed their attitudes so that they were able to do more work than some one who seemingly becomes too easily fatigued. Innumerable cases are cited and there is quite a bit of reference in a superficial and nonmedical way to the literature of fatigue, psychology and psychiatry. The writer seems to know several psychologists and psychiatrists quite well, but some of those

whom she quotes are rather esoteric and perhaps even exotic, so that the advice which she quotes from them probably would not be sustained by most of their colleagues. Marie Ray's is one of the least harmful books of its kind that have been produced. There is no attempt to cause the individual to make a radical change in his personality but rather to reorganize his way of approaching his problems, particularly those which result in fatigue and slow down the effectiveness of the reader. The author is a magazine editor who is amusing as well as interesting and the material which she presents, while of dubious therapeutic value, might serve to aid in the adjustment of problem personalities. One must be hesitant in prescribing a book like this in bibliotherapy because of its exuberance, and certainly it is not meant for a mentally afflicted person who needs psychotherapy; but for the rather maladjusted inferior person who might be helped by reading an inspirational volume it might have a value. Some of the material that she presents is likely to be dramatic enough to give the individual at least a temporary "lift" and in this sense it is not harmful and might even be beneficial. It cannot be considered good science.

Clinical Obstetrics. By A. Lakshmanaswami Mudalliar, B.A., M.D., F.C.O.G., Professor of Obstetrics, Madras Medical College, University of Madras, Madras. Cloth. Price, 27s. Pp. 819, with 213 illustrations. Edinburgh & London: Oliver & Boyd, 1938.

The author has had an unusual clinical experience for many years in one of the largest teaching institutions in India and the Near East. This volume, as its title indicates, completely covers normal and abnormal obstetrics. The subjects are treated in a concise and logical manner. Accepted treatment is suggested for the major complications, although constant recognition is given to the fact that such therapy may be impossible to carry out in special circumstances. The author discusses briefly other treatments advocated in large teaching institutions which have been accorded some recognition. The common operative procedures are discussed in detail and are satisfactorily illustrated. One might take exception to some of the therapeutic suggestions. Uterine tamponade in the case of placenta praevia has been almost completely discarded in large teaching clinics. However, the limitations of this method of therapy are carefully noted. The treatment of eclampsia has been simplified in this country. Sedation, diuresis by intravenous administration of hypertonic dextrose solutions and the induction of labor comprise the most important principles in therapy. The use of tincture of veratrum viride to reduce the blood pressure has fallen into complete discard. Labor is usually initiated by simple rupture of the membranes or the use of a small colpeurynter rather than by the use of bougies. The author's treatment of preeclampsia is in keeping with present day therapy. Vaginal cesarean section is favored in many instances, although its popularity in this country has been on the wane. The tropical diseases and their relationship to pregnancy, labor and the puerperium have been thoroughly covered. So little has been written about these subjects that this presentation is a welcome contribution, particularly to that part of the world in which these diseases are so prevalent. The importance of the diagnosis and treatment of the serious anemias of pregnancy common in India and the Near East is likewise properly emphasized.

The Obliquely Contracted Pelvis, Containing also an Appendix of the Most Important Defects of the Female Pelvis. By Dr. Franz Carl Naegele. Centennial edition, newly translated from the original German by Alfred M. Hellman, M.D., F.A.C.S., and George Musa, M.D. Boards. Price, \$12. Pp. 69, with 16 plates reproduced in the colors of the original edition of 1839. New York: Pynson Printers Incorporated, 1939.

Franz Carl Naegele published the results of many years of laborious work on the obliquely contracted pelvis in a monograph in 1839, and now this centennial edition appears, a fine translation by Alfred M. Hellman and George Musa of New York. The profession owes a debt of gratitude to these men for undertaking and carrying through this work, because there are few copies of the original book in existence. Now every one interested in the science of obstetrics may study one of its most important building stones, a chapter on contracted pelvis. The basis of Naegele's work on obliquely contracted pelvis lies in the accurate and painstaking study of thirty-five pelves, of which several were of his own discovery but most were brought

to his attention by his son and others. Ankylosis of the sacro-iliac joints and arrest of the development of one lateral half of the sacrum formed the main characters of this newly discovered deformity, which he called the obliquely contracted pelvis but to which his name is now attached. The author describes some pelves which have a shape and other characters resembling the true deformity, i. e. intermediate degrees of the deformity. He speaks of the influence of the deformity on labor and the difficulty in diagnosis, which he tries to remove by a full description of the method. In an appendix he describes the most important types of deformed female pelvis—the highly rachitic, the osteomalacic and the exostotic pelvis—nowadays almost unknown in practice. The beautiful and instructive illustrations are in the color of the originals. Nowadays a monograph of this kind seems to have only academic and historical interest. Most obstetricians hardly care whether a woman has a classic Naegele pelvis or any other kind of pelvic obstruction. If the head remains high after a few hours of labor, he does a section and lets it go at that. But to the scientific obstetrician a monograph like the present one is a delicious morsel, and if he should happen on a real Naegele pelvis in his practice he would be able to show the real skill that is in him. Unlike modern medical literature, with its stark science, Naegele's work shows a warm and human light touch. He emphasizes the teacher-pupil relation and exhibits profound gratitude to those who have helped him assemble and investigate rare and difficult material. While every obstetric specialist would gain by reading this monograph, every medical library ought to possess a reference copy. It elevates the science and art of obstetrics.

Medical State Board Examinations: Topical Summaries and Answers. An Organized Review of Actual Questions Given in Medical Licensing Examinations Throughout the United States. By Harold Rybins, A.B., M.D., F.A.C.P., Secretary, New York State Board of Medical Examiners. Fourth edition. Cloth. Price, \$4.50. Pp. 448. Philadelphia, Montreal & London: J. B. Lippincott Company, 1939.

While the author admits in the preface that medical schools are in a better position than examining boards to test the student's academic or encyclopedic knowledge, he has designed this book apparently for the average American medical graduate, who, while admittedly well prepared for the practice of his profession, may approach the ordeal of the licensing examination with some trepidation. The compendium represents a careful study of licensing examinations throughout the United States and for this reason may assist those physicians who desire to select and rearrange in an intelligent and practical manner the material they were given during their undergraduate years.

Theories of Sensation. By A. F. Rawdon-Smith, M.A., Ph.D. Cloth. Price, \$2.75. Pp. 137, with 18 illustrations. Cambridge: University Press, New York: Macmillan Company, 1938.

In this, one of the first three titles announced in the Cambridge Biological Series, Rawdon-Smith has produced a suave and interesting opus. "Theories of Sensation" might lead one to believe that the author is considering primarily physiologic theories which have to do with sensations of all kinds. Such a volume would undoubtedly be of value, but Rawdon-Smith does not write it but rather discusses theories of vision and audition only, giving the physiologic evidence. From the point of view of the various phases of these two sensory phenomena which he discusses, the volume has value. So much experimental evidence, so much discussion of the measurement of the physical properties of sensation is included that the chapters devoted to the formation of a retinal image, the duality of the retinal process, the discrimination of intensity, visual acuity and color vision give one a fairly recent and modern picture of how the laboratory physiologist sees the sensation of vision. There is, perhaps, too much anatomy included in this part, but the author seems to consider it justified as he attempts to present his material from an elementary point of view, although it becomes extremely complex, even to the point at which higher mathematics is used before he is through. In the field of audition, one of the three chapters is devoted to the unadulterated anatomy and physiology of audition with almost nothing presented regarding central function of this sensation. The other two chapters devoted to the hearing sense are on the perception of pitch and theories of the perception of loudness. There is a good bibliography appended and the style is excellent.

The monograph is scarcely comprehensive enough to be a reference book covering completely the sensations of sight and hearing but it certainly would be a valuable accessory in bringing the usual physiological textbook down to date. Some of the author's beliefs do not agree with those of current American ophthalmology or otology but enough of our side of the picture is presented to prevent the author's mildly tendentious thinking from invalidating this material to any great extent. It is a book which can be read with profit by students of medicine as they come to the topics dealt with in it. Specialists in the fields of physiology, otology and ophthalmology might well find it stimulating.

Handbuch der Viruskrankheiten mit besonderer Berücksichtigung ihrer experimentellen Erforschung: Unter Mitarbeit von K. Beller et al. Herausgegeben von Prof. Dr. E. Gildemeister, Vizepräsident des Instituts Robert Koch, Berlin, Prof. Dr. E. Haagen, Abteilungsleiter am Institut Robert Koch, Berlin, und Prof. Dr. O. Waldmann, Direktor der Staatl. Forschungsanstalten, Insel Riems bei Greifswald. In zwei Bänden. Band I. Paper. Price, 40 marks. Pp. 652, with 63 illustrations. Jena: Gustav Fischer, 1939.

This work was undertaken by the authors with the collaboration of thirty other investigators. In the first part of the volume general features, such as the historical development of virus investigations, classification and morphology of the viruses, are considered. Filtration and the manner in which viruses act in the host, as well as outside the host, are adequately discussed. Animal studies and experimental identification of viruses are considered. The cultivation and immunobiology of the viruses are described at length. The second part of the volume is concerned with epidemic fevers under the heads of pustular diseases, vesicular diseases, exanthematic diseases and diseases of septicemic character. An excellent bibliography follows each chapter. The book is well illustrated and contains three excellent colored plates showing the intracellular inclusion bodies (elementary bodies) of many of the viruses. The volume can be heartily recommended to research workers interested in virus diseases.

Keep Fit and Like It. By Dudley B. Reed, M.D., Director of Student Health Service, School of Medicine, University of Chicago. With an Introduction by Morris Fishbein, M.D., Editor, Journal of the American Medical Association. Whittlesey House Health Series, Morris Fishbein, M.D., Editor. Cloth. Price, \$2.50. Pp. 325, with 14 illustrations. New York & London: Whittlesey House, McGraw-Hill Book Company, Inc., 1939.

This book is a valuable prescription for a patient in need of exercise. It is especially adapted to the requirements of the adult intelligent male in average circumstances. Dr. Dudley B. Reed follows the rule of Asclepiades that medicine should be administered to cure quickly, safely and pleasantly (*curare cito, tuto et jucunde*) with the emphasis on *jucunde*. He first discusses exercise from the standpoint of the prescribing physician with chapters on the mechanical, physiologic and psychologic elements, but in such a joyous and interesting fashion that the scientific factors are comfortable and easy to take. He then discusses various games that the adult likes to play from the standpoint of the man who enjoys them. He likes tennis himself and he knows how to play; so will the patient who reads the book. His analysis of footwork, the American twist service, Tilden's style and the value of doubles will be approved by the athletic coach, the tennis enthusiast and the cautious physician prescribing fun and interest for a melancholy menopause. male, who will certainly keep his eye on the ball instead of his troubles. Badminton, horseback riding and skating are similarly treated. He creates an eagerness to go right out and do these excellent things just for the fun of it. Merely reading the book is good therapy. Dr. Reed is well known to the American public as a physician and the professor of hygiene and director of the university health service of the University of Chicago. His literary style ranks with the best in any language. His shrewd and homely understanding of men has seldom been rivaled. The book is far removed from the ordinary popular volume on health. It can be happily and safely recommended to physicians, patients, athletes, fathers, sons and any man who wants a good time out of life. It is part of the Whittlesey House series of popular books on health edited by Dr. Morris Fishbein, and it also carries his appreciative introduction.

Lehrbuch der Röntgendiagnostik. Von H. R. Schinz, W. Baensch und E. Friedl. Nebst Beiträgen von H. Franké et al. Band I: Skelett. Teile 1 und 2. Band II: Innere Organe. Teile 1 und 2. Fourth edition. Paper. Price, 260 marks per set of two volumes. Pp. 544; 545-997; 999-1622; 1623-2182, with 3,671 illustrations. Leipzig: Georg Thieme, 1939.

Medical books are so numerous that it seems impossible for any one to maintain a complete library relating to his own specialty. Many titles are presented, perhaps with the names of the authors unfamiliar, which do not appeal, and the physician may not even take time to look through them. But here is a wonderful work which arrests attention by its size, its attractive appearance and especially by the immediate impression of comprehensiveness when one opens at any page of either volume. It is immediately apparent that one is examining the most authoritative work on diagnostic roentgenology which has yet been published. The new edition has been brought right up to the minute. One seeks in vain to find an omission of any important radiologic discovery relating to diagnosis. The first volume, of nearly 1,000 pages, deals with the necessary knowledge of radiation physics and contains a detailed consideration of normal roentgen anatomy and the various injuries and diseases of bones and joints. An excellent exposition of ventriculography and encephalography rounds out the section on the skull. The second volume is devoted to the roentgenology of internal medicine. It is understood that an English translation is scheduled for early publication in the United States. It will be most welcome.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Workmen's Compensation Acts: Coronary Thrombosis Attributed to Exertion and Mental Strain.—Addington was suffering from a sclerotic condition of the coronary arteries. One night in the course of his employment as an operating engineer in a power plant he experienced extraordinary difficulty in regulating a furnace and was forced repeatedly to climb and descend hurriedly a ladder leading from the furnace room to a boiler and control room above. To add to his troubles, a small explosion of coal dust which had accumulated around the furnace threw him against some machinery and later he was drenched with hot water from a boiler. These incidents left him exhausted, according to his testimony, and when he went home from work he was unable to eat breakfast. He was too restless to sleep for more than an hour. During the afternoon and evening he attended a picnic but was too tired to do more than sit, though he did eat a hearty picnic dinner. About 9 in the evening he was seized by excruciating pains in the chest which radiated down both arms. His condition was subsequently diagnosed as coronary thrombosis and he was disabled from that time on. Contending that the coronary thrombosis was caused by the physical exertion and mental strain that he underwent during his employment the night referred to, he brought proceedings under the workmen's compensation act of Minnesota but was denied compensation. He then appealed to the Supreme Court of Minnesota.

The heart, said the court, is a muscular structure receiving nourishment from blood conducted to its various parts by branches of the two coronary arteries. Coronary thrombosis is the closure of a coronary artery or of one of its branches "by a deposit of platelets and fibrin, components of the blood, so that circulation through the blood vessel is blocked." Something is known about the conditions which give rise to this pathologic condition but its cause is difficult to demonstrate. The closure or obstruction usually occurs where the interior of the artery has been roughened by sclerosis. The deposit usually commences at a time when the circulation is slow; thus nearly half of the cases occur while the person afflicted is in bed. The obstruction may form in a few minutes, or hours or even days may elapse. Physicians called on behalf of the workman testified that his unusual activity and mental strain proved so burdensome to his

heart that it ceased to maintain normal circulation and that the slowed circulation so caused began the formation of the obstruction which culminated the following evening in making itself felt. Physicians called by the employer, however, testified that they were unable to discover any causal connection between the exertion and the thrombosis.

The exact time that the deposit which finally obstructed one of the coronary vessels started to form, continued the court, is impossible of demonstration and any conclusion concerning the time when it did start must proceed solely from inference. Compensation has been granted for disability or death resulting from coronary thrombosis on the ground that exertion attendant on the claimant's employment was the cause. *Hill v. Etchen Motor Co.*, 143 Kan. 655, 56 P. (2d) 103. But in that case the coronary thrombosis manifested itself under such conditions that the exertion during work was the most likely inference as to the cause. Assuming that Addington's circulation was retarded because of cardiac strain or exhaustion caused by physical effort and nervous strain, it might be inferred that the deposit began to form then; but it might be inferred with equal probability that the slowed circulation contributing to its formation was caused by his going to bed on his return from work, or by reason of his resting after the evening meal at the picnic. Experience has shown that it is likely to occur in either of these latter circumstances. To say that it is more likely to have resulted at one time than at another is to state a speculative conclusion for which there is no preponderating proof. The cause may not be attributed to one factor when it may, with equal probability, be attached to another. Since there were several occasions between midnight and 9 in the evening when the workman's circulation would have in the natural course of events slowed so as to permit the formation of a thrombus, and since there was no basis for inferring that it was instituted at one rather than at another of these times, the court believed that there was no proof of an injury arising out of the employment. The workman, was therefore denied compensation.—*Addington v. State (Department of University Farm School) (Minn.)*, 281 N. W. 269.

Birth Control: Contraceptive Literature from Abroad; When Subject to Forfeiture.—A book entitled "Parenthood: Design or Accident," addressed to claimant Nicholas, and copies of a magazine entitled *Marriage Hygiene*, addressed to claimant Himes, came from abroad through the mails and were stopped at the port of New York. After examination the Collector of the Port of New York seized the publications as contraband because they contained information relating to contraception. The United States then brought two libel proceedings to confiscate the publications under section 593 (b) of the Tariff Act of 1930, which provides for forfeiture of any merchandise and punishment of the offender by fine or imprisonment:

If any person fraudulently or knowingly imports or brings into the United States, or assists in so doing, any merchandise contrary to law, or receives, conceals, buys, . . . or in any manner facilitates the transportation, concealment, or sale of such merchandise after importation, knowing the same to have been imported or brought into the United States contrary to law. . . . [Italics supplied.]

For purposes of trial the two proceedings were consolidated. The United States district court, southern district, New York, held that the publications were not subject to forfeiture and dismissed the libels. The government then appealed to the United States circuit court of appeals, second circuit.

The circuit court of appeals upheld the district court in refusing to declare the publications forfeited. The court pointed out that under postal regulations and joint regulations of the United States Treasury and Post Office departments prohibited printed matter arriving by mail from abroad must inevitably be examined at the border and detained. Printed matter so detained, as was the printed matter in this case, has not yet been imported or brought into the United States within the meaning of section 593 (b) of the Tariff Act and is therefore not subject to forfeiture under that section. Furthermore, while section 305 of the Tariff Act provides for the seizure of drugs, medicines or articles for the prevention of conception on their appearance at any customs office, that section has no relation to publications relating to contraception.

The court refused, however, to hold that the publications should necessarily be delivered to the addressees, the claimants. It is one thing, the court observed, to say that the publications may not be confiscated and another that the United States Post Office must forward them to the addressees. The court pointed out that on two previous occasions it had held that contraceptive devices may have lawful uses and that statutes prohibiting them should be read as forbidding them only when unlawfully employed. *Youngs Rubber Corporation v. C. I. Lee & Co.*, 45 F. (2d) 103, and *United States v. One Package*, 86 F. (2d) 737, abstracted in THE JOURNAL, April 30, 1938, page 1518. Likewise, contraceptive books and pamphlets, as those in the instant case, are lawful in the hands of those who would not abuse the information they contain. The court ordered, therefore, that the magazines seized in this case, being lawful in the hands of physicians, scientists and the like, be delivered to claimant Himes, who was the American editor of the magazine, since he was the most appropriate distributor of such magazines to persons lawfully entitled to possess them. With respect to the book seized, however, the court was unable to say whether claimant Nicholas was or was not one of those in whose hands it would be lawful. The only information the record contained about him was that he was not a physician. The burden rested on him at least to go forward with the evidence to show that he belonged to one of the privileged classes entitled to receive such information. In the judgment of the court, therefore, although the book should not be confiscated, it should not be delivered to the addressee but should go to the Dead Letter Office.—*United States v. Nicholas; Same v. Himes*, 19 F. Supp. 1017; 97 F. (2d) 510.

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1929 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

- Comparative Effects of Amphetamine Sulfate (Benzedrine Sulfate), Paredrine and Propadrine on Blood Pressure. J. Loman, M. Rinkel and A. Myerson, Boston.—p. 89.

Congenital Heart Disease in Childhood.—Ash and Harshaw reviewed the records of all the children (230) with congenital cardiac defects who were admitted to the wards or cardiac clinic of the Children's Hospital from 1922 to 1936. Since they were interested not only in the incidence of congenital cardiac lesions but also in their prognostic significance, during the first six months of 1938 they tried to trace and to reexamine all children not under current observation. They were successful in tracing 80 per cent of the children. Of the forty-one children who could not be located, twenty-eight had attained the age of at least 2 years when they were last seen, so that the course in the first two years is known in 217 instances, or 94.3 per cent, of the group. The total number of deaths was 102 (53.9 per cent of those traced in 1938 and 47 per cent of those who were 2 years of age or older when they were last examined). Of the deaths, 73 per cent had occurred within the first year of life and 78 per cent within the first two years. In slightly more than one half of the cases (52.9 per cent) the final illness was of infectious origin. Pneumonia headed the list of infections, causing 39 per cent of the deaths. In one third of the deaths circulatory inadequacy was a prominent feature. Of ten of the thirty-eight patients who came to necropsy, no cause of death could be found other than circulatory failure. However, no death was due to any of the common childhood diseases. It was observed that infants with congenital cardiac defects tend to be slow to gain weight and delayed in growth. Malnutrition of a noticeable degree was present in sixty-nine children. In later life these children may remain dwarfed and of fragile build. In some individuals, however, a spurt of growth occurs as puberty is reached. Mental deficiency was a not infrequent occurrence. Operative procedures were well borne, including thirty-three tonsillectomies and adenoidectomies (two of cyanotic individuals), one splenectomy, one mastoidectomy, one herniorrhaphy and one open reduction for subluxation of the elbow. There are many instances of longevity among noncyanotic individuals with congenital cardiac defects but, on the whole, the prognosis is poor for the cyanotic individual. However, a hopeless prognosis should not be assumed for any child who has survived infancy. Cyanotic children should not be deprived of schooling. Whether cyanosis is present or absent, exercise should not be restricted beyond the limiting capacity of the heart itself. Children with congenital lesions are more fortunate than those with rheumatic fever in that they do not have the additional handicap of continued systemic and myocardial infection. In spite of startling murmurs and cardiac enlargement, the functional capacity is often normal.

Leukocyte Counts and Sedimentation Rates in Children.

—Osgood and his collaborators determined the total, differential and absolute leukocyte counts and the sedimentation rates for children from 8 to 14 years of age and found that there were no significant age or sex differences. The differential and absolute cell counts show a higher proportion of lymphocytes (from 1,500 to 6,500) and a lower proportion of neutrophil lobocytes (from 1,500 to 6,500) than have usually been given. The probable explanation for this is that most of the data previously reported have not been obtained from studies of strictly healthy persons. The sedimentation rates form a skew curve, with the greater number of determinations falling in the lower ranges. It is probable that the rate of 15 mm. in forty-five minutes, which tops 80 per cent of the results, represents the strict upper limit of normal and that the higher rates are due to mild chronic infection in the tonsils, teeth or sinuses not detectable in the routine physical examination.

- *Malabsorption of Fat (Intestinal Lipodystrophy of Whipple): Report of Case. H. L. Reinhart and S. J. Wilson, Columbus, Ohio.—p. 483.

Malabsorption of Fat.—Reinhart and Wilson report a case of intestinal lipodystrophy similar to that first described by Whipple. The early clinical manifestations were predominantly those of a blood dyscrasia, which was carefully studied in its hematologic aspects. These studies led to a tentative diagnosis of a benign pseudoleukemic lymphocytosis, relative neutropenia and a moderate hypochromic microcytic anemia. With the development of chylous ascites an obstruction of the thoracic duct due to lymphadenosis or carcinoma was postulated. In contrast with the cases reported by Whipple, Blumgart and Jarcho, fatty diarrhea was not a prominent clinical symptom and there was no evidence of rheumatic fever. The massive deposition of fat in the sinuses of the mesenteric and retroperitoneal lymph nodes represents a quantitative increase of lipids. Emaciation and depletion of body fat, among the striking clinical manifestations of these cases, suggest the possibility of increased excretion of fat into the intestine. Inadequate data are available to suggest a change of the bacterial flora of the intestine which might increase cholesterol absorption. The evidence suggests massive excretion of fat into the intestine and an increased reabsorption of fat from the intestine. The term "intestinal lipodystrophy" as suggested by Whipple would seem to be most appropriate. In contrast with the xanthomatous diseases, these cases present large aggregates of extracellular as well as intracellular fat. A fundamentally different type of cell is probably involved.

Syphilimetry with Exclusion Slide Tests.—Levine and his associates found that the microscopic slide precipitation tests for the exclusion of syphilis reacting with a small amount of reagin have served well as criteria of the presence or absence of the disease in forty-four cases. The series comprised primary, secondary and congenital syphilis observed within several months of infection. During treatment the blood tests were frequently repeated and, when at least three consecutive exclusion slide tests at intervals of a week or more were negative, a spinal fluid examination was made and, if this was negative for evidence of syphilis, treatment was discontinued. The average period of treatment (continuous, alternating arsenicals and bismuth compounds) was twenty-three months, the minimum five weeks, the maximum more than five years. Seventy patients have been followed clinically, roentgenographically, serologically and by examination of the spinal fluid for from eight months to twelve years and found to date to be free from all signs and symptoms of the disease. Studies of the central nervous system and the cardiovascular system are indicated in these cases, but it is concluded by the authors that the exclusion slide tests for syphilis are of the greatest value in the early detection of the disease and more satisfactory in the control of its adequate treatment than therapy by schedule.

Gonorrhea Treated with Sulfanilamide.—Waugh and Dawber used sulfanilamide in the treatment of 473 hospitalized male gonorrhea patients. They attempted to standardize the dosage; 120 grains (8 Gm.) of sulfanilamide in four divided doses for the first twenty-four hours and then 60 grains (4 Gm.) in four divided doses daily for fourteen days longer. Of the 473 patients 75 per cent completed the full fifteen days of treatment. Of the patients treated with sulfanilamide alone 92 per cent had clear urine (except for some shreds) compared to only 26 per cent among patients treated by the old routine methods

used during six months before treatment with sulfanilamide was instituted. There were 65 per cent apparent recoveries from gonorrhea. There was no appreciable difference in the percentage of apparent recoveries between acute and chronic infections. The full fifteen days of treatment was not completed by 12.5 per cent of the patients because of both severe and mild reactions, and another 12.5 per cent did not complete the full treatment because of lack of improvement or unwillingness to remain in the hospital. There were a few apparent recoveries after as few as three days of treatment with sulfanilamide. Complications of gonorrheal urethritis other than prostatitis were present at the time of admission and before treatment with sulfanilamide was instituted in 12.5 per cent of the 473 patients. There were 90 per cent apparent recoveries in these cases, compared to 64 per cent in the so-called uncomplicated cases, in many of which prostatitis was present in addition to urethritis. Complications during treatment occurred in 0.4 per cent. Reactions sufficiently severe to warrant discontinuance of sulfanilamide occurred in 8 per cent of the 473 cases, among which were included dermatitis, fever, anorexia, nausea or vomiting, abdominal pains, diarrhea, mental confusion, severe anemia, severe anemia with jaundice and granulocytopenia with angina. Among blood counts done in 314 cases, 17.5 per cent showed some degree of anemia; but only 3.2 per cent of the blood counts were below 3.5 million red blood cells.

Coexisting Tuberculosis and Syphilis.—From January 1928 to January 1938, routine serologic tests for syphilis were performed on 2,160 patients admitted to the Laurel Heights State Tuberculosis Sanatorium. Warring studied the interrelations of tuberculosis, syphilis and antisyphilitic treatment in the cases in which the two diseases coexisted. The incidence of syphilis in these admissions was 4 per cent (eighty-seven cases). There were twenty-two instances showing positive or doubtful reactions that could not be given a final diagnosis of syphilis. There were eleven repeatedly doubtful reactors. These constitute 10 per cent of the total reactors and it is felt that this is a larger proportion than is generally found in the syphilis clinics. This brings up the question of false doubtful or false positive reactions for syphilis obtained in tuberculous patients. Parran and Emerson sent blood from 458 supposedly nonsyphilitic tuberculous patients to five eminent serologists. They found both typical and atypical false doubtful and false positive results in these serums and felt that tuberculous toxemia might contribute a confusing factor to serologic tests for syphilis. It was ascertained that the incidence of active tuberculosis in syphilitic persons is not greater than in nonsyphilitic individuals. The extent of the tuberculosis was practically the same in the two groups when they were admitted to the sanatorium. However, pulmonary tuberculosis in the syphilitic patients did not respond as favorably to sanatorium treatment as did the disease in the nonsyphilitic persons. Antisyphilitic treatment might be suspected as the cause of the poor showing among the syphilitic group of patients. Whether the administration of antisyphilitic drugs can be responsible for unfavorable changes in the course of pulmonary tuberculosis is not known. Patients can be selected carefully for treatment and the drugs given with caution and still a spread of the phthisis may occur. Yet remissions are notorious in uncomplicated tuberculosis itself. So even with all the facts of a given case at hand it is usually impossible to say

whether the increase in the pulmonary disease was to be expected by the law of possibility or was the direct result of antisyphilitic treatment. The response of syphilis to treatment of patients with tuberculosis does not appear to differ from the course of the disease in nontuberculous persons.

Reactions from Ergot and Ergotamine Tartrate.—Comfort and Erickson review the literature dealing with untoward effects from the use of ergot or of ergotamine tartrate preparations. To these they add two personal cases in which untoward effects developed following the use of ergotamine tartrate for the control of pruritus. The untoward effects that have been reported have followed administration of doses larger than those compatible with good practice, when small doses were used the reactions apparently depending on the existence of an idiosyncrasy to the drug. Some untoward effects have followed the use of the drug in the usual doses and were apparently due to a cumulative action of the drug. In spite of these many instances of ergotism the authors do not intend to discourage administration of ergotamine tartrate in proper doses, provided adequate precautions are taken. The drug has proved itself too valuable for this, especially in the control of pruritus and migraine. Instead, they would emphasize the contraindications to its use, the danger of the development of ergotism and the fact that the onset of ergotism may be suspected early by frequent examination of the arteries of the extremities for spasm and by recognition of its early symptoms. Prompt and early recognition of ergotism and the discontinuation of ergot or ergotamine tartrate medication, followed by the administration of vasodilating drugs, are the prerequisites for the avoidance of irreparable damage.

Vitamin A of Human Liver in Tuberculosis.—Crimm and Short point out that the average liver content of vitamin A of fifty tuberculous patients (342 units per gram of liver) compares favorably with that reported (331 units) previously for healthy persons. However, this is far from the saturation point, as evidenced by the wide variation between it and individual cases. The average is about one fifth of the maximal finding (1,640 units). The distribution according to age is not significant, except for the fact that in older persons the vitamin A content is somewhat increased. The abundant nutrition given tuberculous patients and the prolonged duration of the fibrotic disease would account for these results. The vitamin A content of the human liver approached depletion in 14 per cent of the patients. All patients with enteritis had values below the average. Therefore the administration of generous doses of vitamin A is indicated in tuberculosis with pyrexia or enteritis.

Dihydratichysterol for Parathyroid Deficiency.—The effects of dihydratichysterol on five patients with parathyroid deficiency following thyroidectomy from five months to thirteen years previously are reported by Rose and Sunderman. The patients were given a diet the calcium content of which was approximately 1 Gm. daily. All rejected food was weighed and the calcium content calculated. The results confirm the previous reports in that dihydratichysterol was effective in relieving the symptoms of parathyroid deficiency and increasing the concentration of serum calcium. The danger of producing toxic symptoms and hypercalcemia by large doses is emphasized by such an experience in one patient. In four patients the response to dihydratichysterol was relatively prompt; the concentration of total serum calcium returned to normal, with corresponding relief of symptoms, in from four to nine days after the beginning of treatment. The fifth patient had received no previous treatment and presented relatively mild symptoms; she showed a slow, progressive increase in concentration of serum calcium, with corresponding gradual clinical improvement. The degree of hypocalcemia and the severity of symptoms are not equally correlative.

Sulfanilamide for Bacterial Endocarditis.—During the past year Spink and Crago gave sulfanilamide to twelve patients with subacute bacterial endocarditis. Organisms were recovered repeatedly from the blood of the twelve patients. In the first case there was evidence of meningitis due to *Staphylococcus albus* in addition to bacterial endocarditis. After the diagnosis of bacterial endocarditis had been established, the patient was apparently "cured" and remained so for seven months. Of considerable interest were the minimal changes observed in the endocardium at necropsy. Bacterial endocarditis was apparently engrafted on a previously normal valve. The lack of extensive damage to the mitral valve over such a long period might be explained on the basis of invasion of tissues by an organism of low virulence or by the bacteriostatic effect of sulfanilamide. The second patient has been in good health for nine months after sulfanilamide therapy. Before sulfanilamide was given a quantitative study of blood cultures showed thirty colonies of *Streptococcus viridans* per cubic centimeter of blood on one occasion and 200 colonies on another. In the remaining ten cases, in which the etiologic agent was *Streptococcus viridans*, the authors do not believe that sulfanilamide therapy had any desirable effect on the course of the disease. In six of the twelve cases sulfanilamide did render the blood stream sterile, determined by cultures of venous blood. However, this bactericidal effect appeared to be only temporary, except in the first two cases. In two cases in which the blood was rendered free from bacteria by sulfanilamide, bacteremia was again established when the drug was discontinued for forty-eight hours. Since the prolonged administration of sulfanilamide did not sterilize the blood in six cases it may be that certain strains of *Streptococcus viridans* are more readily destroyed by sulfanilamide than others. This problem is being studied. All of the twelve patients were febrile during their illnesses. There was a definite decline of the temperature of four coincident with the

administration of sulfanilamide. In five cases the drug did not appear to affect either the temperature or the bacteremia. In two sulfanilamide therapy had no effect on either the fever or the bacteremia and in one after sulfanilamide was given the temperature became and remained normal but the bacteremia was unaffected. Although all the patients had some degree of anemia during their illness, in only one could a rapid decline in the hemoglobin and erythrocyte levels be attributed to sulfanilamide. There was no further decline when the drug was discontinued. In no instance did sulfanilamide cause a depression of the leukocyte level. In two cases there was a definite and marked increase of the leukocytes during the administration of sulfanilamide. No definite relation between the amount of sulfanilamide present in the blood and its effect on the bacteremia could be elicited. The authors suggest that, since sulfanilamide may have a bacteriostatic effect on some strains of *Streptococcus viridans*, sulfanilamide probably should be administered to any patient with valvular lesions who may be subjected to oral surgical procedures. It is well known that, after the extraction of teeth or after a tonsillectomy, temporary bacteremia with *Streptococcus viridans* may result.

Myasthenia Gravis and Hyperthyroidism.—Thorner reports a case of myasthenia gravis in which the appearance of hyperthyroid symptoms was attended by a lessening of the myasthenic symptoms. The administration of thyroid substance coincided with a period of remission of the myasthenic symptoms. In two cases previously reported by others there was some evidence of this same type of "seesaw" balance between myasthenia gravis and exophthalmic goiter. For these reasons the author suggests that the two diseases are mutually antagonistic and that this relation is a matter of scientific, but not of immediate therapeutic, importance.

Nitrogen and Calcium Balances as Affected by Growth.

—Johnston and Maroney estimated the nitrogen balance, and in some instances the calcium balance, in children of the prepuberty and postpuberty periods following the administration

for short periods of a preparation of the pituitary growth hormone and gonadotropic substance. A variety of responses followed—anabolic, catabolic and negative—which the authors explain as probably being conditioned by the presence or absence of a hormone defect, the state of the stores as judged by the control balance and the age of the child. Subjects included several girls with menstrual difficulties at puberty, four dwarfs—a cretin, one with achondroplasia and two with ateleiosis—and a number of children who apparently had no endocrine abnormalities. Instances of complete loss of response in the nature of antihormone effect were encountered.

Neutralization of Epidemic Influenza Virus.—Horsfall investigated the quantitative relationships of the neutralization of epidemic influenza virus by homologous antiserum. The results of the experiments indicate that under certain conditions a linear relationship exists between the quantity of virus neutralized and the quantity of serum. When the logarithm of the amount of virus neutralized is plotted against the logarithm of the quantity of serum, the neutralization of virus appears to approximate a straight line. This relationship has been found to be the same for the serum of a ferret convalescent from experimental influenza and the serum of a rabbit immunized with the virus. Calculation of both the 50 per cent mortality end point and the so-called 50 per cent maximal score end point has shown the relationship to be independent of the end point chosen. By means of the linear relationship between virus and antiserum it is possible to determine a fixed, rather than a relative, value for the neutralizing capacity of a serum.

Anesthesia and Sulfanilamide.—Adriani studied the reactions of rats treated with sulfanilamide and subjected to anesthesia with the various commonly used drugs. He finds that rats treated with sulfanilamide react with little difference to volatile or gaseous anesthetics than do untreated controls. However, the barbituric acid derivatives of the short and ultra short acting groups which are ordinarily used for surgical anesthesia are not borne well by rats having had sulfanilamide. Rats treated with sulfanilamide and then given evipal, pentothal, thiethylamyl, amylal or pentobarbital sodium showed effects unlike untreated rats. The subanesthetic doses became anesthetic and often lethal. Anesthetic doses were usually lethal. The thio derivatives of barbituric acid were the worst offenders. Rats treated with sulfanilamide and allowed four days for recovery did not show this reaction. It was also less intense early in sulfanilamide therapy and more intense with increased dosage of the drug. It is suggested that the combination of sulfanilamide and barbiturates may be unwise in human therapy.

Concentrating Tubercle Bacilli in Sputum.—Sullivan and Sears outline an enzyme-digestion method, using a crude preparation of the enzyme papain as a digestant, for concentrating the tubercle bacilli in sputum, which they believe has the following advantages: 1. Digestion of sputum is rapid, usually being complete within ten to fifteen minutes. 2. No neutralization of the digestant is required. 3. The sediment obtained from the enzyme digestion adheres well to glass slides, allowing thicker smears. 4. Cultures and animal inoculations can be made from the sediment after appropriate treatment to destroy non-acid fast organisms, which are not affected by the digestant.

Blood Pressure During Insulin Shock.—Pessin reports the data on blood pressure changes of four patients undergoing insulin shock treatment. As one of these patients received two series of treatments, five sets of data are presented. The blood pressure of each patient was taken immediately before the injection of a shock producing dose of insulin and each half hour subsequently until treatment for the day was terminated. This was repeated each day during the entire course of treatment. From a total of 1,504 blood pressure readings the arithmetical mean (average) for each half hour on each patient was computed. The data of all five graphs indicate that insulin in doses large enough to produce shock caused a rise in the mean systolic blood pressure which occurred from one to two hours (most frequently one and one half hours) after the injection of insulin and which varied from 8 to 37 mm. of mercury. In two graphs this rise remained throughout the treatment, in two the mean systolic blood pressure dropped from this high level, especially during the last half hour, but remained above the initial mean reading, and in one graph the drop in mean systolic pressure was continuous after the second hour and fell below the initial level at the end of treatment. Variations in the mean diastolic pressure were much less in degree and slower in onset. In two graphs the diastolic pressure remained relatively constant, in two there was a rise of from 5 to 13 mm. of mercury, which began two hours after the injection of insulin, and in one the mean diastolic pressure fell gradually during the entire treatment. With a single exception the mean pulse pressure was from 5 to 17 points higher at the end of treatment. Maximal variations in individual consecutive blood pressure readings were as follows: systolic, rise of 60 mm. and fall of 76 mm.; diastolic, rise of 40 and fall of 24 mm. of mercury.

Effect of Operations on Blood Ascorbic Acid.—Lund determined the level of ascorbic acid before and after major operations in the blood plasma of forty-three patients. In nearly every case there was a prompt fall after operation from the original level. In a few cases the level began to rise again after four or five days. A low plasma vitamin C value in blood

drawn from a patient immediately after operation may not be so significant an indication of depleted reserves as is a low value before operation. In nine of these forty-three cases the preoperative ascorbic acid level in the plasma was at least 0.8 mg. (normal) per hundred cubic centimeters of plasma, in ten between 0.5 and 0.8 mg. (low normal), in eleven between 0.2 and 0.5 mg. and in thirteen it was less than 0.2 mg. Of patients with normal preoperative levels the vitamin level was reduced postoperatively about 30 per cent on the average and not more than 50 per cent in any individual case within three days after operation. The patients who showed suboptimal but not extremely low preoperative values had an average drop of 50 per cent, and several patients showed a loss of nearly all the vitamin from the blood. In the third group of patients the extremely low original level either persisted or dropped still further. In four cases there was a late rise to a level equal to or higher than the original. In the thirteen cases in which the preoperative values (less than 0.2 mg.) were at the scurvy level the original levels were so low that there could be no appreciable drop. In only two cases was there a late rise in the plasma level.

Bromide Permeability Quotient in Mongolism and Epilepsy.—Mettler states that the bromide permeability quotient of mongoloids is, as a class, lower than that of normal individuals. Among epileptic individuals the quotient tends to decrease with age while among normal children it tends to increase.

Sudden Death in Mental Patients.—In the 2,038 deaths that occurred at the Rockland State Hospital during a period of seven years, Thompson found forty that were sudden and unexpected. The causes of these forty deaths were assigned to

acute exhaustion of the insane. The author shows that these deaths are related or possibly due to dysfunction of the hypothalamus. The observations seem to indicate an irritative lesion of the hypothalamus. This might further suggest that the whole picture of mania (hyperexcitability) can be explained on the basis of pathologic changes of the hypothalamus. This would indicate an organic cause of hyperexcitability and therefore of mania. Future investigation of acute exhaustive deaths should include detailed microscopic observation of this region of the brain. Blood sugar determinations are recommended. The trial of ergotamine tartrate is suggested as treatment for hyperexcitability.

Potassium in Allergy.—Bloom and Grauman find that the symptoms of various diseases (hay fever, pollinosis, chronic sinusitis, asthma, urticaria, eczema, angioneurotic edema and migraine) generally considered to be allergic respond, in many instances, to the oral administration of small doses of potassium salts. There are, likewise, many instances of failure. The authors' intention is only to indicate the types of allergic diseases in which some response has been obtained in order that others may give this method a more extensive trial. There is evidence which lends much support to the concept that electrolytes have a fundamental role in allergy. The authors state that it is impossible at present to say whether electrolyte changes are secondary to the allergic state or whether it is an essential abnormality of electrolyte metabolism that permits the allergic state to develop. That the latter hypothesis is correct seems likely, particularly in view of the food sensitivity cases, in which the expected allergic reaction can be prevented by the preliminary administration of potassium chloride. Should this hypothesis become established it would appear that the proteins, about which practically all the studies in allergy have centered, are significant only as substances which evoke symptoms when the underlying electrolyte mechanisms of the body are altered. It is important to distinguish between the intricate immune mechanisms in the body which come into play after the entrance of a protein allergenic substance and the alterations of electrolyte balance. It is suggested by the authors, as a working hypothesis, that when the electrolyte balance is normal allergic manifestations do not appear. With regard to the contraindications, potassium should not be used in cases of Addison's disease. Potassium might be harmful in some cases of disturbed renal or cardiac function, and perhaps allergic individuals with these complications should not be treated with potassium. So far the authors have had no actual experiences with these complications. In view of a few untoward reactions in asthma they feel that potassium should not be generally used for chronic asthma, particularly for status asthmaticus. In pollen asthma of adults they recommend its use but advise caution. In the treatment of pollinosis of children they advise even greater care until further studies have been made. Side effects occur: occasional mild diuresis, rare diarrhea and slight rhinorrhea, but ordinarily these are not troublesome. Gastrointestinal pain is readily avoided by administering potassium chloride in a dilute aqueous solution, e. g. 10 grains (0.65 Gm.) in a glass of water.

The dosage varies considerably. To some patients with severe hay fever they found it necessary to give 10 grains six times a day. Some of the patients with sinusitis required only 5 grains (0.03 Gm.) three times a day. In other instances such as simple food sensitivity, a single dose of 5 grains may be all that is necessary. The maximal daily dose has been 80 grains (5.2 Gm.).

Insulin and Diets for Underweight.—Since their previous report (abstracted in THE JOURNAL May 21, 1938, p. 1792) of fifteen underweight patients treated with insulin and a high caloric diet the McCastors have continued this practice for 120 additional underweight persons. The procedure was similar to their earlier work with the exception that the initial dose of insulin was as high as 30 units a day in some cases instead of 15 units as in the first fifteen cases. Of the total patients twenty-two did not return for treatment after the first visit when the instructions and plan of treatment were outlined. The psychologic factors are seen here operating at the outset. The patient is unwilling to be convinced that he can gain weight. Many of these patients could be regarded as self-destructive types of individuals. When consciously expressed, the reasons given for this negative attitude were mostly "fear of the needle, fear of the ill effects from insulin." Twelve persons did not return after the second visit and their reasons were not ascertainable. More than 10 pounds (4.5 Kg.) was gained by thirty of the patients, for whom the highest dose of insulin was 90 units daily. Forty patients gained from 5 to 10 pounds (2.2 to 4.5 Kg.) on a daily dosage of 60 units of insulin. In twenty-eight cases the gain in weight was from 1 to 5 pounds (0.5 to 2.2 Kg.) on from 60 to 120 units of insulin daily. The foregoing gains in weight occurred in from a few days up to fifty days. Of two patients who failed to gain much weight, one gained 2 pounds (1 Kg.) in thirteen days on 120 units daily and failed to gain any more, one gained 6 pounds (2.7 Kg.) in thirty-two days and after this no further gain in weight occurred. The authors find that any of the insulins on the market can be used with safety and that when allergic symptoms developed from the use of one insulin a change to another brand or type of insulin usually curtailed the symptoms.

Potassium Content of Muscle in Disease.—Cumings records the potassium content found in muscles in a variety of muscular diseases, with special reference to dystrophia myotonica and myasthenia gravis, in which conditions he thinks no similar investigations have been made. The effect of the administration of prostigmine on the muscle potassium has been studied. The content of potassium in affected muscles was normal in cases of progressive muscular atrophy, simple atrophy, Charcot-Marie-Tooth disease, myositis, wasting associated with cerebral tumor and peripheral neuritis. Abnormal muscles containing a low potassium concentration were seen in cases of pseudohypertrophic muscular dystrophy, peroneal atrophy, marked atrophy with fibrous tissue replacement, myopathy with marked fibrosis and myotonia. The muscles in this group of cases contain a large excess of fat or of fibrous tissue. Muscles from two normal subjects, two cases of myotonia and two cases of myasthenia gravis were investigated. Muscles from the normal patients showed no appreciable alteration in potassium content after the administration of prostigmine, but the potassium content of muscles in the cases of myotonia and of myasthenia after prostigmine approached the normal muscle potassium level. Concurrently with the return to a normal potassium level there was a return to normal muscle function in patients with myasthenia gravis. Patients with myotonia showed no clinical improvement as regards either the myotonia or their normal muscular function, although the potassium content approached the normal, and this was not surprising as all the muscles showed some signs of atrophy.

Methyl Testosterone Orally.—Foss found methyl testosterone to be effective when given orally. He states that potency was fully maintained in a postpuberal eunuch with 100 mg. of the preparation daily, and a lower dosage of 50 mg. is effective. All the signs of puberty were produced rapidly in two cases of genital hypoplasia affecting not only sexual but physical development. It is probable that in such cases much smaller doses would be adequate. Methyl testosterone,

10 mg. daily, was given to three patients with dysmenorrhea for whom some relief had been found from injection of testosterone propionate. By two it was taken for fourteen days immediately before menstruation, with no improvement, but the third, taking the methyl testosterone in the middle of the cycle, obtained relief. The eunuch complained of some symptoms such as slight nausea, anorexia and dyspepsia, which were relieved by alkali.

Sterilization, Economic Expediency and Inheritance.

—Southwick studied the social history records of a group of institutionalized patients, each of whom had had one or more children before commitment, while on parole or after discharge. In many cases, data concerning the early environmental conditions, school attainments and intelligence quotients of these children and their parents were recorded. A group of 488 children were located, in 441 of whom records concerning the early environmental conditions were available. On the basis of the precept that any sound sterilization policy should be based on a clearcut demonstration that the germ plasm of the person to be sterilized must be distinctly deleterious to the welfare of society, the intelligence quotients of these 488 children were determined to see whether an "undifferentiated mental deficiency" might be considered to depend on hereditary factors. Of the 441 children whose records concerning the early developmental environment were procured, 15.42 per cent were cared for by parents, grandparents or other relatives, 24.26 per cent had to be cared for at a custodial institution, and the remaining 60.32 per cent were eventually and finally cared for by orphanages, boarding homes or adoption. There were records concerning the school attainments in 114 cases. Of these, 45.61 per cent were patients at an institution for the care of the feeble-minded, 36.84 per cent were definitely retarded in their school attainments, 17.54 per cent were in a grade normal for their age and none had attained to a grade in advance of that normal for their age. In order to study more adequately the intelligence quotient distribution of this group of children, all the data concerning the intelligence quotient determinations were presented graphically. In all, there were determinations for 138 children and seventy-two parents (patients). The curves were presented separately and show a smooth, normal distribution in both cases, with modes respectively at 65 and 55 points of intelligence quotient. The continuously variable nature of the intelligence ratings in connection with the nature of the shift of the mode in both of these groups indicates that intelligence is an inherited, continuously variable, quantitative trait, produced by a large number of independently inherited allelomorph pairs, which, by dint of the large number of combinations possible, produce innumerable quantitative gradations. The group of institutionalized parents would represent a group of allelomorphs that would be predominantly in a homozygous low intelligence quotient condition. Such a concentration of low intelligence quotient genes produces persons who are incapable of caring for themselves. To this extent, such genes are definitely and distinctly deleterious to the welfare of society.

Passive Control of Scarlet Fever.—According to Bradshaw a new scarlet fever antitoxin was tried in the wards of a children's hospital as a means of passive prophylaxis. The scarlet fever antitoxin, according to the makers, is refined and concentrated by a process of "selective and controlled digestion of the inactive, reaction-producing proteins by means of proteolytic enzymes." Most Dick positive patients received their serum within a few hours of admission and virtually all within twenty-four hours. From July 27, 1937, to Aug. 4, 1938, 658 patients received the serum. During the course of the trial, one case of scarlet fever developed in the ward. The child had been in the ward forty-eight hours before the serum was administered, and signs of scarlet fever appeared within a few hours of the injection. The serum has also been employed in the control of scarlet fever in the general medical and surgical wards. During the period under review there have been fourteen primary cases of scarlet fever in the general wards, involving 135 Dick positive contacts. They were dealt with as the cases in the children's wards. No secondary cases of scarlet fever developed. Of the total of 793 patients receiving serum, only ten had serum reactions.

Bacteriostatic Action of Sulfanilamide in Vitro.

—Stamp records results of experiments which indicate that it is possible to isolate from broth cultures of group C hemolytic streptococci a substance capable of antagonizing the bacteriostatic action of sulfanilamide and sulfapyridine in different mediums. The substance may be extracted from the bacterial cells by means of dilute ammonium hydroxide but is not removed in appreciable amounts by extraction with water or dilute hydrochloric acid. The activity of the substance is not affected by heating to 100 C. and does not appear to be highly specific, since it produces a growth-promoting effect in the presence of the drugs not only on the homologous strain but also on a strain belonging to a different serologic group. The substance is active in low concentrations under favorable conditions exerting an appreciable effect in a dilution of 1:1,000,000, while a marked effect has been obtained in nearly all experiments in a concentration of 1:10,000. Chemical analysis indicates that the substance consists of material of relatively low molecular weight and is free from protein. Further purification and analysis of the active substance must be carried out before any definite indication can be obtained as to its real chemical nature and the way it produces its antibacteriostatic effect. The active fraction may contain a necessary nutritive factor, possibly an essential amino acid the production of which is interfered with by the action of the drugs. It may be one of the rarer amino acids which the organisms have to synthesize or it may even consist of a more complex molecule necessary for the synthesis of bacterial protein. There is the further possibility that the active substance is an essential part of the enzyme system affected by the drugs. It may be that the activity of the drugs is directed not against an actual enzyme but rather against a substance of the nature of a coenzyme on the presence of which in many cases the activity

of enzymes has been shown to be entirely dependent. The presence of such a substance in the active fraction might therefore be responsible for the effects produced. An apparently similar fraction has also been isolated from a culture of a group A hemolytic streptococcus.

Three-Dye Treatment of Burns.—Devine describes a three-dye method of treating burns and scalds, which is of particular value for industrial and military first aid purposes, because it at once substantially relieves pain and commences a treatment which will be carried on in the hospital. In twenty-seven cases the three-dye method of treatment was used and in ten the tannic acid or tannic acid and flavine method. Included in this series were patients from the bush fire areas. The three-dye mixture consists of a 1 per cent aqueous solution of gentian violet and of brilliant green, and a 0.1 per cent solution of neutral acriflavine. The mixture is quite stable and can be kept for any length of time. The three-dye mixture is swabbed over the burnt area and no dressing is applied. No attempt is made to "clean up" the burnt area. Trauma with a nail brush or friction of any sort would be expected merely to force infected material from the surface through the coagulated area. It is inconceivable that scrubbing would serve to sterilize the area. When a large area of skin is involved, a preliminary injection of morphine may sometimes be necessary to relieve pain centrally. When the area of the burn is not great, the local relief of pain afforded by the use of the dye is generally sufficient. Blisters on the burnt area are snipped and the dead skin is removed, and the burnt area is dabbed, painted or sprayed with the three-dye mixture. A second application after about half an hour is usually given but is not always necessary. Tanning commences immediately. The tan formed is not so thick as that produced by tannic acid and it is more flexible. Delayed blisters appearing within a few days after the burn require snipping and removal of dead skin and a reapplication of the dyes. No dressings are used. Clothing is so arranged by outpatients that as far as possible no pressure is applied to the burnt area and, with the same end in view, hospitalized patients are put into suitable postures and covered with cradles. Patients with minor burns merely require an occasional observation to see whether any softening of the eschar has occurred. Patients with more extensive burns require careful and continuous treatment. During the process of epithelization care must be taken, by the use of splints, to prevent contractures due to scarring. Death in the early stages is nearly always due to shock, and 80 per cent of deaths occur in the first two days. After a week the main cause of death is bronchopneumonia. With a view to the prevention of bronchopneumonia, some of the patients were allowed up early and encouraged to exercise as much as possible. In the thirty-seven cases there were two deaths, occur-

ring in men who had been burnt by and had inhaled acetic anhydride; one was treated by the three-dye method and the other by the tannic acid and flavine method. Both died within two days. Of the twenty-seven patients treated by the three-dye method, none became obviously infected, one doubtfully. Of the ten patients treated by tannic acid or tannic acid and flavine, four showed infection. There appeared to be no difference between the amount of shock experienced after tanning by the patients who were treated by the tannic acid and those treated by the three-dye method. The advantages of the three-dye method of treatment that the author lists are: 1. The mixture is inexpensive and keeps indefinitely, and therefore it is always on hand for emergencies. 2. The mixture forms a coagulum rapidly and with only one or two applications, and the coagulum when formed is more pliable than that formed by tannic acid. 3. As a result of the analgesic action of the gentian violet, pain is alleviated rapidly. 4. The mixture appears to be more efficient in preventing infection than tannic acid. The two disadvantages of the method are that the mixture stains clothing and linen and in very small children and babies the coagulum formed may be too thick and it may crack at the edges.

Serum and Vaccine Therapy with Sulfanilamide or Sulfapyridine.—Fleming states that even with the most sensitive organisms sulfanilamide and sulfapyridine do not effect a cure in every case, and he offers evidence to show that the results obtained by increasing the power of the defensive mechanism, in other words, by increasing the immunity, are, in combination with these drugs, far superior to immunotherapy or chemotherapy alone. The immunity can be increased specifically by vaccine and serums and nonspecifically by a great variety of measures. He states that there is as yet no published work on the combination of serum therapy and sulfapyridine, but he shows in vitro that the addition of antipneumococcus serum greatly enhances the antipneumococcal power of a mixture of human blood and sulfapyridine. In his studies the combination of immune serum and sulfapyridine was the only one effective in preventing the growth of pneumococci in human blood and he has little doubt that the same combination will be most effective in the treatment of pneumonia in man. However, when the leukocytes are removed from the blood the combination of sulfapyridine and immune serum is without effect. Others have put forth evidence that the state of immunity of the patient plays a large part in the success or failure of sulfanilamide treatment. This clinical evidence is not conclusive, but he believes that it is significant when taken in conjunction with the experimental evidence that he presents. He sums up the new chemotherapy by sulfanilamide and sulfapyridine. These drugs act on certain sensitive bacteria in some way so that the mechanism of the body completes the task by destroying the bacteria. The result, therefore, which will be obtained in any particular case will depend on the sensitiveness of the infecting organism to the drug and the immunity of the patient. The ordinary individual may, as far as the common pyogenic organisms are concerned, be regarded as having a medium degree of immunity which can be increased actively or passively. In an acute case one cannot tell whether the infecting organism is one which is sensitive to these drugs so that, if the patient is to have the best chance, every endeavor should be made at the same time that the drug is administered to increase the patient's immunity by vaccines or serums or by nonspecific measures. Serums are obtainable only for certain infections, but vaccines can be obtained, or can be prepared readily, for almost every acute bacterial infection.

Secondary Tetany in Hyperestrogenemia.—Marañon and his associates point out that although the pathogenesis of tetany has been rightfully dominated by the notion of hypoparathyroidism, there are nevertheless other endocrine factors, distinct from the parathyroids, which may intervene in the genesis of tetany. Clinical observations which were published recently by Sergeant and Mamou directed attention to the influence of genital hormones in the pathogenesis of certain types of tetany. Marañon and his collaborators describe four cases of tetany in which the genital hormones played a part. The first one concerned a young woman with probable spasmophilia or latent tetany and dysovarium of the hyperestrogenemic type; an injection of estrogen, by accident intravenous, produced an intense and typical attack of tetany. The second case concerned a cryptorchid, half castrated man with evident genital insufficiency, who had latent tetany with spontaneous paroxysmic crises. His feminoid character coincided with an abnormal secretion of estrogen. Considerable improvement was obtained by treatment with testicular hormone. The third patient was a man with cholecystitis, psoriasis, arthropathy, chronic tetany and old orchitis and hypogonadism. Examination disclosed considerable estrogenuria. Treatment with testicular hormone counteracted the symptoms of tetany. The fourth patient was a woman with dysovarium due to excess of estrogen and with symptoms of premenstrual tetany. The administration of lutein substances and of testosterone produced a favorable therapeutic effect. As the most likely explanation of this relation between genital function and tetany, the authors regard the hypothesis that in women there exists an absolute or relative hypersecretion of estrogen or a diminution of the lutein hormone and in men there exists considerable estrogenuria and doubtlessly diminution of the testicular hormone.

Spondylomalacia in Biliary Cirrhosis.—Loeper and his associates report the clinical history of a woman aged 69 who had a chronic progressive melanodermic and icterogenic hepatitis without pancreatic symptoms and without calculi. The disorder was complicated by malacic lesions of the vertebrae. The diagnosis proved difficult at first. The icterus by retention was for a long time too evident and too prolonged to permit the diagnosis of biliary cirrhosis. The history was rather that of a calculous cirrhosis, but there was neither choledochal obliteration nor vesical lithiasis. The obstruction of an intrahepatic biliary canal, although possible, escaped the authors in the anatomic examination. They diagnosed the disorder as chronic icterogenic fibrous hepatitis. The osseous lesions involving the lumbar vertebrae attracted special attention. After citing osseous changes described by others in the course of biliary cirrhosis, the authors show that the osseous changes in the reported case differ from those described in the literature. They became manifest suddenly by acute pain in the lumbar region, and vertebral osteoporosis was discovered by radiography in a woman who had been icteric for many months. The calcemia was increased. The pains and the calcification were counteracted by the combined treatment with intravenous injections of calcium gluconate and the oral administration of irradiated ergosterol. The necropsy finally revealed a hyperplasia of the parathyroid tissue. This physio-

pathologic connection is common in senile osteoporosis and in osteomalacia caused by deficiency. Its relation to chronic icterus raises interesting discussions. The authors show that investigation on the calcium metabolism in patients with icterus have produced divergent conclusions but that the literature contains reports about osseous decalcifications and osteoporosis in the course of prolonged icterus. Moreover, they cite animal experiments in which prolonged ligation of the choledochus resulted in a diminution of the calcium content of the blood and in osseous rarefaction. On the other hand, decalcification is frequently observed in patients and animals with biliary fistula. It is striking that the osseous disturbances observed in the reported case are on the whole identical with those engendered by the derivation of the bile from the intestine. After citing clinical and experimental evidence to this effect, the authors point out that the decalcification after biliary fistulization is explained by the fact that the suppression of the bile in the intestine prevents the assimilation of fats and of liposoluble vitamins. The lime soaps precipitate and are not absorbed in the alkaline milieu and in the absence of biliary salts. The authors think that such a calcium and vitamin deficiency can well be invoked in the described case because the conditions of the intestinal assimilation of fats were the same as after exclusion of the biliary passages. Not only does the spondylomalacia recall osteopathy due to insufficiency but the physiopathologic mechanism seems likewise identical. The authors point out that a knowledge of these facts enabled Leriche to treat osteomalacia resulting from choledochal drainage by means of osseous grafts and parathyroidectomy and that they themselves obtained favorable results by recalcification with calcium and irradiated ergosterol.

Auriculoventricular Dissociation in Typhoid.—Godel and Stéphan report three cases of auriculoventricular dissociation clinically and electrocardiographically observed during the course of typhoid. Standard three lead tracings were made during fever and in defervescence. Electrocardiac tracings made at the end of the first week of the first patient (aged 18 years) revealed enlargement of the PR interval, low voltage in the auriculoventricular complexes in lead 1 and flattening of the T wave in all three leads. The second electrocardiogram taken at the end of the second week disclosed the same enlargement of the PR interval and indications of dissociation in lead 3, sinus rhythm remaining regular at about 90. Digitalin administered for a presystolic murmur during the middle of the second week had, as electrocardiac observation showed, no effect on dissociation, since disturbances of the conduction tract preceded it and regressed despite continual dosage; the PR interval likewise remained the same, though 75 drops of digitalin was given during convalescence. The patient was observed repeatedly after release from the hospital. No traces of cardiac disease were detected. Cardiograms taken of the second patient (aged 15 years) disclosed an enlarged S wave and an exaggerated, slightly diphasic, amplitude of the T wave in leads 1 and 2. In defervescence, auriculoventricular disturbances appeared, when amphibolic oscillations fluctuated between normal temperature in the morning and 104 F. in the evening, while the PR interval, regular during the course of the fever, began to lengthen and pass rapidly from 0.12 second to 0.16 to 0.20 second of time and the ST segment dipped below the iso-electric level. The T wave was less ample in lead 1 and negative in leads 2 and 3. Electrocardiac tracings made at the end of the defervescence period revealed dissociation and other indications of sinus arrhythmia in

lead 3. Convalescence was normal with normality reestablished in the PR interval. The history of the third patient (aged 12 years) disclosed dissociation not in conformity with classic heart block. Electrical readings first made with temperature at 104 F. indicated large amplitude of the auricular peak with marked diphasis in leads 1 and 2, progressive lengthening with subsequent shortening of the PR interval and the T wave tending to flatten out and disappear completely in lead 2. Defervescence was marked by arrhythmia of a pronounced type. The irregularity of the sinus rhythm was so great that no two successive equidistant PP intervals were discoverable in lead 1. Ventricular followed auricular complexes at distances of from 0.24 to 0.32 second, at times completely merging with the auricular complex or anticipating it. Two independent rhythms established themselves, the idioventricular rhythm consistently regular at forty-five a minute. Tracings showed complete dissociation with the ventricular rhythm regular, the auricular less regular and slower. With increased temperature stabilization, sinus rhythm was accelerated and auriculoventricular sequences became increasingly numerous. Tracings made during a relapse that lasted about two weeks revealed regular rhythm and normal auriculoventricular relations in the three leads. However, on the third day of defervescence slight sinus arrhythmia was traced in lead 1. Significant bradyarrhythmia accompanied convalescence. Electrocardiograms revealed the same sinus disturbances and phenomena of dissociation as before the relapse. After eight days auriculoventricular action was restored to normal condition. The authors point out the indications of this atypical dissociation. According to their analysis, disorders of the conductive tract do not necessarily imply myocardial toxoinfections but may be due to extracardiac pathogenesis. Disorders of the sympathetic nerve system may well extend to the conductive system and induce vagotonia. Prognosis of cardiac disturbances secondary to vagal hyperfunction is ordinarily benign.

Serial Roentgenograms of Colon.—Rachet and Arnous criticize the present methods of roentgenologic examination of the colon, particularly the ordinary barium sulfate enema, and show that the imperfections of these methods make it necessary to accept the diagnoses made with them with great caution and reservation. Serial roentgenography, as employed for gastroduodenal examination, provides a maximum of precision in the differentiation of organic and functional images. In comparing several roentgenograms that are taken during peristaltic contractions, two types of deformities of the intestinal walls can be visualized, those which are modified by the peristalsis and those which are not, the first ones being functional and the second ones organic. The authors raise the question why this method of serial roentgenography is not employed for the examination of the colon. Since the rare and slight character of the colonic movements is probably the cause of the rejection of this method, they show that this problem can be solved by the artificial production of peristaltic contractions. In preparing the patient for the serial roentgenograms of the colon, they avoid all laxatives and purgative enemas. The evening before, the patient is given a large enema of salt water (1.5 per cent); in the morning, an hour before the examination, the same type of enema is given and if this does not return absolutely clean a third enema, consisting of 200 cc. of lukewarm water, is given immediately before the examination. As the precautions which are indispensable for obtaining clear roentgenograms, the authors stress the following: 1. The contrast enema must be homogeneous, because the presence of barium conglomerates may distort the interpretation. 2. The temperature of liquid should be 37 C. (98.6 F.), for if the enema is too cold it may elicit a colic chill. 3. The pressure of the enema should be as low as possible. 4. By means of a final insufflation, the walls are distended. In order to stimulate peristalsis, the authors employ the subcutaneous injection of prostigmine, but they think that the same end can be obtained with

other substances, for instance the posterior lobe of the hypophysis. The serial roentgenograms, from five to eight in number, are taken at regular intervals, usually every ten minutes. The authors report a number of illustrative cases. They admit that serial roentgenoscopy applied to the colon is still under investigation and that, like all new methods, it requires improvement. They think that it advances the precision of the diagnosis in three ways: the estimation of the extension of the lesions, the estimation of the operability of a tumor and perhaps also the determination of the nature of the lesion.

*Arterial Retinal Tension in Intracranial Tumors: Its Importance for Topographic Diagnosis and Its Role in Formation of Choked Disk. G. de Morsier, M. Monnier and E. B. Streiff.—p. 702.

Arterial Retinal Tension in Intracranial Tumors.—De Morsier and his co-workers review the evidence of twenty-one cases of intracranial tumors, verified as such surgically or at necropsy, in order to determine the significance of cerebral tumors for retinal and spinal tension and the formation of choked disk. The age of the patients ranged between 11 and 60 years. The authors established two indexes: a retinohumoral tension index, obtained by dividing the normal diastolic retinal tension by the normal diastolic humoral tension of the twenty-one patients, and a retinospinal tension index, ascertained by dividing the retinal tension by the spinal tension. Methods of measurement and arithmetical results are indicated. They found (1) that, contrary to accepted views, intracranial tumors were accompanied much more frequently by retinal hypotension or normal retinal tension than by retinal hypertension (only six of the twenty-one [28 per cent] had retinohumoral hypertension, twelve had hypotension, and three were normal); (2) that the retinohumoral tension index unmistakably indicated variations according to the site of the cranial tumor, with greater retinal hypertension accompanying tumors in the posterior cerebral fossa (two cases adverse). From these observations the authors deduce that other factors besides brain compression are productive of retinal hypertension (frequently observed, e. g. in sequels of craniocerebral traumas). Retinal tension may well be conditioned by disturbances in the control centers of cerebral vasomotricity. In their study of retinospinal tension in relation to choked disk the authors were led to formulate the following observations: 1. The retinospinal tension index is not affected by the position of the tumor. 2. A certain connection exists between spinal tension and choked disk formation, papilledema invariably arising when spinal tension rose to 80 or higher but capable of developing with spinal tension as low as 40. 3. Choked disk appeared (with two exceptions) when the retinospinal tension index fell below 0.58 (below half the normal rate of about 1.2). The authors think that these observations, which they admit need to be studied more extensively, have interpretative significance for noncerebral tumors. They point out that choked disk is much less frequent in intracranial tumors than is generally assumed. The low frequency (eight times in twenty-one cases, or 38 per cent) is ascribed by them to the regular employment of encephalography.

New Chemotherapeutic (Sulfanilamidopyridine) in Human Brucellosis. H. Scholer.—p. 685.

Lambliasis and Cancer of Biliary Passages.—Grott says that different parasites harbored by the human organism may be factors in the development of neoplasms either because of their continuous irritating action or because of their metabolic products. In the course of studies on lambliasis of the biliary passages he observed three carriers of *Lambia intestinalis* who also had cancer of the biliary passages. After reporting the clinical histories of these patients, he emphasizes that these

observations and reports in the literature convinced him that, in case of cancer of the biliary passages, lambliaosis must be taken into consideration as a possible causal factor. Moreover, lambliaosis should be searched for in all intestinal diseases of obscure etiology. If lambliaosis has been established, it is necessary to keep the patient under careful control until complete cure has been established in order to prevent the carrier of the parasites from becoming a further source of infection. This is the more justified since lambliaosis can be effectively treated with preparations of the acridine group, such as atabrine.

*McClure and Aldrich Test in Relation to Surgical Intervention in Chronic Appendicitis. P. Gagliardi.—p. 517.

McClure and Aldrich Test in Appendicitis.—Gagliardi followed the behavior of the McClure and Aldrich test (intra-dermal injection of sodium chloride solution) in relation to a surgical intervention in forty cases of various inflammatory and noninflammatory diseases, especially chronic appendicitis. The test was carried out in twenty cases some days after the operation and in nineteen cases some days before and some days after the operation. In all cases the test was carried out according to the original technic. Determinations of the arterial pressure were also carried out in the group. The author found that the results of the test and the duration of the wheal are not in relation to the sex of the patients, the nature (either inflammatory or noninflammatory) of the disease, the presence of preedema and the variations of the arterial pressure. In cases of inflammatory disease the results of the test are in relation to the operation. The reaction of the second test is more intense and lasting than that of the first one. In some cases in the group an erythematous reaction around the wheal developed both after the first test and after the second one. According to the author the reaction is a reaction of the skin to the injected sodium chloride solution, in the production of which vascular (cutaneous capillaries), constitutional and other nonidentifiable factors are present. The occurrence of an erythematous reaction in many cases shows that the reaction is a local reaction of the skin. The reaction is of a defensive nature. The increased intensity of the reaction after the operation (as compared with the results of the test before the operation) show that the organic forces of defense (which previous to the operation were divided between the pathologic local focus and the local reaction of the skin) are entirely diverted to the skin after removal of the pathologic focus.

*Antitoxic Action of Ascorbic Acid and of Extracts of Adrenal Cortex in Experimental Diphtheria. A. Galeotti Flori.—p. 577.

Vitamin C and Abdominal Purpura of Schoenlein-Henoch's Type. F. Copello.—p. 587.

Ascorbic Acid and Adrenal Cortex Extract in Diphtheria.—Galeotti Flori found, by means of experiments, that ascorbic acid alone or in association with adrenal cortex extract has an antitoxic action on diphtheria toxin in vitro. The action depends on the duration of the contact between the acid and the toxin and also on the amount of toxin in the ascorbic acid-diphtheria toxin mixture. Ascorbic acid alone, or in association with adrenal cortex extract, as well as the adrenal extract alone, has an antitoxic action on diphtheria toxin in living animals, provided the dose of the toxin administered is smaller than the minimal mortal dose. Otherwise the toxin is not neutralized. Ascorbic acid administered separately during antiserum treatment does not increase the effects of antiserum in the course of experimental diphtheria. The author concludes that, although experimental results cannot be applied to the clinical field as a whole, his results show that ascorbic acid alone or in association with adrenal cortex extract is not a substitute for diphtheria antiserum, which is the proper treatment of diphtheria. However, either ascorbic acid or adrenal cortex extract can be used as a coadjuvant to antiserum.

Origin and Development of Epidermal Tumors. A. Lautenschläger.—p. 545.

Differential Diagnosis of Calcified Meniscus. T. Eck.—p. 547.

Rib Fractures.—From Kirschner's clinic at Heidelberg, Matthes and Thelen report four cases of rib fracture in which the etiologic factor was muscular overwork. All four patients were young men in good general health who for a short time (from two to five weeks) preceding the disability were performing heavy muscular work to which they were unaccustomed. The fractures involved the second or the second and third ribs at their costocartilaginous junction. The authors consider the mechanism to be uncoordinated, exaggerated pull over a period of time of the insertions of the pectoralis minor and the upper portion of the trapezius muscle. The diagnosis of the condition may be arrived at from consideration of the history and the appearance on the seventh to fourteenth day of a moderately painful swelling at the typical localization and on the presence of pain caused by movements of the shoulder girdle, particularly when the pectoralis minor and the upper portion of the trapezius are brought into action. A roentgenogram is of little value because the fracture is through the cartilaginous portion of the rib. The treatment consists of rest, of local anesthesia of the fractured area in cases of severe pain and later of diathermy and motion: After four weeks of treatment, patients are recommended for a lighter occupation.

Deficiency of Vitamin A.—Von Drigalski and his associates say that, in view of the difficulties which are encountered in the demonstration of vitamin A in the blood, it has been deemed advisable to search for vitamin deficiencies and to estimate, from the quantities of vitamin that are required to counteract them, the adequacy of the supply of vitamin A. Since the disturbance of the adaptation capacity of the eye, that is, the "night blindness due to vitamin A deficiency," is an easily detectable early symptom of the deficiency of vitamin A, it has been investigated by many workers. After reviewing the results obtained by some investigators in healthy persons and in patients and after pointing out that the vitamin A metabolism in pregnant women deserves especial attention, the author describes his own studies on the adaptation capacity of the eye in fifty healthy adults, ninety pregnant women (most of them in their eighth or ninth month of pregnancy), thirteen nursing mothers and fifty patients. The tests were made with a five point adaptometer of Birch-Hirschfeld. Summarizing the results of his adaptometric studies, he says that among the fifty healthy adults he observed three mild cases of deficient dark adaptation indicative of an insufficiency of vitamin A; among the fifty patients, twelve cases of medium severity and three severe cases; among the ninety pregnant women, eleven cases of moderate severity and four severe cases, and among the thirteen nursing mothers, three mild cases. By continuous control examinations on persons treated with vitamin A, the author was able to obtain definite figures on the vitamin A deficiencies. The deficits varied between 72,000 and more than 300,000 international units of vitamin A, corresponding to between 43 and 200 mg. of beta-carotene. He discusses the role of nutrition in the causation of vitamin A deficiency and gives especial attention to the increased requirements of pregnant women and nursing mothers. He shows that there is a wide span between the minimal and optimal vitamin A supply.

Early Treatment of Male Gonorrhea with Uliron (Sulfanilamide). H. J. Barnewitz.—p. 1021.

Fluorescence Microscopy in Demonstration of Tubercle Bacilli.—According to Weiler and Kunz, several investigators have found that, in the demonstration of tubercle bacilli, Hagemann's method of fluorescence microscopy (abstracted in THE JOURNAL June 5, 1937, p. 2006, and July 17, 1937, p. 243) produces much better results than the methods of Ehrlich-Ziehl-Neelsen or of Konrich. Dabelstein, however, saw no advantage in Hagemann's method. In order to eliminate autosuggestive factors, which might have had some influence in previous investigations, in which the comparative tests had been made by the same person, the authors decided to conduct their tests independently. Kunz examined the specimens of sputum according to Konrich's technic and Weiler according to Hagemann's fluorescence microscopy. They studied 1,000 specimens in all and a subsequent comparison of the results disclosed a decided superiority of Hagemann's fluorescence microscopy. It yielded 26 per cent positive results, whereas Konrich's method produced only 9.1 per cent positive results. Another advantage of fluorescence microscopy is that it saves time. Moreover, in the differential diagnosis between tubercle bacilli and saprophytic acid-fast rods, fluorescence microscopy is more reliable than are the other methods. Systematic examination of various bacteria (cocci, rods and vibrios) by means of fluorescence microscopy never revealed fluorescent forms in the cocci and vibrios and disclosed them only rarely in the acid-fast rods. Exceptions to this rule were the diphtheria and pseudodiphtheria bacilli, for on examination with fluorescence microscopy following staining with auramine they were found to contain fluorescent granules, but their peculiar position and their slight fluorescence prevented their being mistaken for tubercle bacilli. The slight fluorescence exhibited by acid-fast saprophytes following staining with auramine could be reduced or counteracted by treatment with hydrochloric acid alcohol and thus they could be differentiated from tubercle bacilli. Disadvantages of fluorescence microscopy are that it requires expensive apparatus and that it may cause dizziness, fatigue and coughing in the worker who employs the method for long periods. It is suggested that these shortcomings might be eliminated.

Mongolian Idiocy. J. Illing.—p. 353.

Renal Rickets.—Loeschke presents a clinical, anatomopathologic and metabolic study on a girl aged 6 years with renal rickets observed for two and one-half months. Familial anamnesis was good; likewise the personal history of the patient during the first two years of her life until an antrotomy was performed. The patient was distinctly undersized and undernourished with a skeletal structure indicating general calcium deficiency (knock knees). The urine was turbidly yellow and contained albumin, leukocytes, epithelium and bacteria. Pyuria attested serious anatomic and functional changes in the entire urogenital system. Therapy consisted in daily administration for forty-eight days of viosterol (initial dose of 10 drops two times increased to 12 drops two times = 40 cc.) but with no effect on osteoporosis. Therapy for pyuria and renal insufficiency could not be undertaken. The patient's death from uremia was preceded by edematous formations and increasing anemia, with the hemoglobin count finally as low as 23 per cent. The necropsy revealed a grave pyelonephritic kidney contraction, productive of renal insufficiency, together with bilateral hydronephrosis and a purely hyperplastic growth of epithelial bodies enlarged to twice the normal weight, as well as other characteristics. Metabolic analysis indicated a

manifest tendency to phosphate retention and preferential elimination by way of the intestine. Bone examination revealed an enormous mineral impoverishment and abnormal water surplus. In the epiphyses mineral insufficiency was accompanied by a qualitative modification in the inorganic composition of the bones. The author summarizes his conclusions as follows: Renal rickets is in all essentials clearly a vitamin D deficiency of nephritic origin, primarily induced by phosphate retention secondary to renal insufficiency. Phosphate retention is causative of hyperplasia of epithelial bodies and, in consequence, of mineral imbalance. The bone structure presents characteristics of its own.

*Pyurias in Children. H. Seidlmayer.—p. 92.

Pyurias in Children.—Seidlmayer says that pyuria is a symptom which may occur in a number of disorders. The term was coined because in infants and young children it is difficult to differentiate between vesical, ureteral and pyelic inflammations, the patients being unable to describe their subjective symptoms, such as pains or pressure in the renal region, burning feeling on urination and the urge to urinate. This report is based on the cases of pyuria which were observed at the internal department of the children's clinic at the University of Munich. Especial attention is given to pyuria in boys, in whom it is much less frequent than in girls. The majority of cases of pyuria in boys of the nursling age (nearly four fifths) develop as a complication of another infection (usually influenza), which reduces the resistance. Deformities or calculi were found to be causal factors only rarely. About two thirds of all cases of pyuria in boys of the nursling age were completely cured. Of the remaining third the majority died during the first year of life. Chronic pyuria developed in only a few of the cases. The often repeated statement that in boys of the nursling age pyuria is a much more serious condition than in girls, in that its lethality is supposedly higher and its duration longer, is not corroborated in the author's material, particularly since sulfanilamide has been employed in the treatment of pyuria. Compared with other therapeutic methods, sulfanilamide produces the best results in children with pyuria. The author says that sulfanilamide was usually administered by mouth. However, in cases in which vomiting made the oral administration difficult, sulfanilamide was given parenterally, usually by intramuscular injection. The urine was free from pathologic constituents after from four to seven days of treatment with sulfanilamide. In order to avoid relapses the author advises that medication with sulfanilamide be continued for about a week after the urine has become normal.

*Rational Treatment of Burns. S. M. Kalmanovskiy.—p. 63.

Treatment of Burns.—According to Kalmanovskiy, infection of the burned surface, rather than the absorption of the products of broken down albumin, is the principal factor in the pathogenesis of burns and is the most frequent cause of death. The treatment has for its aim the combating of shock and dehydration and prevention of infection. Immediately on admission the patient is given a hypodermic injection of morphine or pantopon. Blebs are removed and the entire burned surface is sprayed or painted with 1 per cent aqueous solution of methylene blue or of gentian violet. The patient is laid on a sterile sheet with a cradle framework over him, which is like-

wise covered with a sterile sheet. The desired degree of warmth is maintained by electric lamps placed underneath the cradle. The patients are urged to drink large amounts of warm sweetened tea, from 5 to 6 liters daily. The spraying or painting with methylene blue or with gentian violet is repeated daily for about ten days. With the beginning of demarcation on about the seventh to tenth day, the formed scabs are painted with petrolatum to expedite their sloughing. Patients with severe burns are given sulfanilamide on the assumption that streptococcal infection has the leading part in the infection of burned areas. Since the adoption of the open method the author has been able to save several patients with as much as one third of the entire skin area burned.

*Erythema Nodosum in Nursling. D. P. R. Keizer.—p. 1503.

Xerophthalmia Among Indonesian Population. Maas.—p. 1512.

Erythema Nodosum.—Keizer shows that, although the tuberculous origin of erythema nodosum is of considerable importance, there are still other etiologic factors, because cases are observed in which tuberculosis is certainly not the cause. The author cites two cases of his own observation, one of which he had described previously. The patient was a boy, aged 9, who had a bacillary dysentery. Five days later he presented the typical aspects of erythema nodosum, which three days later were followed by pains in the joints. The tuberculin reaction was negative and remained so. Moreover, the boy remained free from tuberculosis subsequently and his family history was likewise free from tuberculosis. The author thinks that in this case the dysentery was the primary disorder and that the erythema nodosum is to be regarded as an anaphylactic manifestation. The second patient with erythema nodosum was a nursing aged 6 months. Here again the examination disclosed no signs indicating a tuberculous origin of the erythema nodosum, but the child had measles, repeated attacks of bronchitis and bronchopneumonia. The author thinks that the attack of measles was the primary cause and that the relapsing bronchitis and the bronchopneumonia elicited the allergic reaction.

*Contribution to Neurogenic Conception of Pathogenesis of Peptic Ulcer. E. Ask-Upmark.—p. 336.

Thyrototoxic Crisis and Hypersensitivity to Iodine.—Wijnblad says that during the last two years he administered compound solution of iodine by means of continuous intravenous drip with dextrose-saline solution. He used this method in cases of thyrototoxic crisis and in those of severe thyrototoxicosis in connection with subtotal and total thyroidectomies. This method is of great value because it has extended the indications for surgical treatment to the severest cases of thyrototoxicosis. The administration of compound solution of iodine by intravenous drip has so far been used in ten cases. One case is especially noteworthy because it shows that the intravenous administration of large doses of iodine produces a different reaction than does the oral medication with small doses. The patient, a woman aged 28 who had grave thyrototoxicosis, proved to be hypersensitive to the oral administration of iodine, for she developed exanthem and fever and her general condition was impaired. In a spontaneous crisis, large quantities of iodine were given by intravenous drip and there were no signs of

iodism and the crisis was cut short. Continued treatment with iodine demonstrated that the crisis or the treatment had desensitized the patient. The woman was operated on and recovered.

Conservative Operative Treatment of Hydronephrosis.—Petrén says that formerly nephrectomy was performed too often in cases of hydronephrosis and that during the last two decades renal surgery has advanced along more conservative lines. Nowadays the majority of surgeons are agreed that nephrectomy should be done only in cases in which the hydronephrosis is so advanced that the kidney has no longer any functional value, or in the event of a severe complicating infection, provided, of course, the condition of the other kidney makes such an intervention permissible and advisable. In other cases of hydronephrosis, conservative operative measures should be resorted to. After reviewing the literature on the so-called plastic operations for hydronephrosis, the author reports three cases of hydronephrosis in which conservative plastic operations were performed and which were reexamined from two and three quarters to five years after the operation. The hydronephrosis was of a moderate degree and the changes at the uteropelvic junction or in the upper part of the ureter were not pronounced. Fenger's ureteropelvioplasty was performed in two of the cases and in the third case a pyelo-ureteral anastomosis was made. During the subsequent years (from two and three fourths to five) the patients were entirely or almost entirely relieved from their earlier hydronephrotic disorders and urography, performed at the after-examination, showed that the dilatation of the renal pelvis had decreased and its emptying capacity improved.

Neurogenic Pathogenesis of Peptic Ulcer.—Ask-Upmark cites Cushing's opinion on the neurogenic origin of peptic ulcer and then presents his own investigations on the gastric secretion of ten patients with tumors of the brain. He found that in some of these cases the gastric secretion was unchanged, in others it was reduced and in still others it was increased. Reduced secretion was observed in one case of pituitary adenoma; increased secretion with peptic ulcer and hematemesis was detected in one case of cystic cerebellar tumor. The author describes three other observations in which peptic ulcer developed in connection with intracranial lesions. One patient was an adult who sustained a head injury with a blunt object; the second patient had received a shot injury, the bullet being lodged in the cerebellomedullary cistern; the third patient was a newborn infant presumably injured during delivery. The author expresses the opinion that the peptic factor and the neurogenic factor in the genesis of ulcer are made compatible by these observations. He emphasizes that still other factors are at work in the pathogenesis of peptic ulcer: the liver function is frequently impaired and evidence is presented supporting the idea of a close relationship between the central nervous system, the liver and carbohydrate metabolism, disturbances of this functional unit being liable to favor the development of peptic ulcers.

Apparatus for Oxygen Treatment: Addendum. N. Bay.—p. 784.

Treatment of Psychoses with Metrazol Shock.—Hahnemann reports that in 151 (73 per cent) of the 207 cases of schizophrenia treated according to von Meduna's convulsion therapy the duration of the psychosis had been from two to twenty-eight years. Full remission resulted in forty cases, partial remission in sixty-nine. In the thirty-six cases in which the disorder had existed for less than one year, full remission was attained in twenty-five (69 per cent), partial remission in six (17 per cent) and no improvement in five (14 per cent). Treatment with metrazol was also given in twenty-four cases of depression and fifteen of manic-depressive psychosis. Full remission occurred in all cases. The importance of a rational psychotherapy simultaneously with the shock treatment is stressed.

Factors Influencing Ethical Concepts and Ideals Among Medical Students

TRAWICK H. STUBBS AND DEAN ROBERTS

ATLANTA, GA.

"Just why do you want to be a doctor?" was the question put to embryonic doctors during their first week in Medical School at Emory University. Four consecutive freshman classes answered it. Their answers furnished the background for a panel discussion at the National Convention of the Association of Medical Students at Philadelphia last December on "Factors Influencing Ethical Concepts and Ideals Among Medical Students."

The subject was discussed under four general heads: 1. What ideals and attitudes do freshman medical students have? 2. What factors influence the development of and changes in these attitudes and ideals? 3. What ideals and attitudes is it desirable for a young doctor to have? 4. What practical steps might be taken to facilitate the development of these desirable ideals? Two half hour periods of open discussion were allowed following topics 2 and 4, during which time several controversial points were debated. No attempt has been made to include the entire panel in this paper. Only the more important points are discussed.

The choice of this subject immediately places one in a realm where definite measurements are impossible, and necessarily the bulk of the material presented represents personal opinions. However, in the absence of more tangible data a sincere exchange of opinion will no doubt lead to a better understanding of the problems involved. In developing this subject an attempt has been made to follow the sound advice of Dr. Howard W. Haggard, of Yale University, who admonishes "I would suggest that you approach your problem in this social matter with the same scientific skepticism and the same meticulous avoidance of post hoc reasoning as that with

which you approach your researches in physiological sciences." It is recognized, of course, that every medical school presents a different problem. Some of the statements here will apply to only a few schools; others have more general application.

THE FRESHMAN

Naturally the most obvious factor involved in this consideration is the fundamental character and integrity of the student as he reaches medical school. Certain maturing processes are common to young men of this age regardless of what profession they have chosen. Many of these have, of course, begun long before the student reaches medical school and will continue after he leaves. Of those factors peculiar to medical students, some begin to exert an influence during the premedical training. For example, many students, intent on thorough preparation, so concentrate on the premedical sciences that they neglect the development of a broader cultural background which would aid in the development of a well rounded philosophy.

The premedical student frequently is faced with the necessity of readjusting many indoctrinated concepts and authoritarian beliefs to conform to new concepts and scientific truths with which he becomes acquainted. Often he fails to work through this dilemma to a satisfactory, mature philosophy and is unable to discriminate between the valuable and the worthless in the ideas which he discards. The process of developing a coherent philosophy is still in its very early stages for many men entering medical school.

In medical school the emphasis on scientific subjects is continued, and for many there is an inability to relate the information harmoniously because the conflicts and contradictions have not been eliminated by the substitution of a revised and adequate philosophy.

Important in the outlook of the freshman medical student is his incentive for entering medicine. Many men have no doubt drifted into

In the preparation of this panel the opinions and advice of many deans of medical schools and other medical authorities were sought. Excerpts from their letters, of which more than fifty were received, are being prepared in pamphlet form and will be available to those interested. Requests should be addressed to The Journal of The Association of Medical Students, Editorial Office, New York University Medical School, 477 First Avenue, New York City, or to Resident Committee, Association of Medical Students, University of Illinois College of Medicine, Chicago, Ill.

the position of beginning a medical career without ever having thought through logically and completely their reasons for choosing this profession. Those who have been influenced principally by the desires of parents or relatives are likely to be and to remain somewhat immature. Those whose motives are social prestige, or the attainment of wealth and prominence are likely to respond to situations in a manner quite different from those whose motives are founded on a sincere desire to serve. Some student entering medicine may see only the glory and the romance in the profession without realizing that back of it is a life of hardship. He has a too sentimental conception of the profession—dreams of just going from place to place healing people and doing good. He fails to realize that he frequently has to get his hands dirty, that osteo smells bad, that rectals are necessary, that disease is not often pretty and clean, that he will often have to stand helpless and wait for death.

NARROWING INFLUENCES

There are a number of factors in the lives of medical students which militate against the development of well rounded individuals. The mass of medical knowledge which must be acquired in four years has grown so tremendous that it taxes the ability of even the best student. The average student finds himself confronted with a task that requires every ounce of his effort. He is frightened by the possibility of a failure which will permanently eliminate his chances of becoming a doctor. Under this pressure of crowded curriculum and fear, the student has little use for anything not directly connected with medicine. There is no time left for him to think in terms of relating himself to society as a whole. The process of the integration of the personality is neglected. Those factors by which one develops a coherent philosophy and by which he relates himself to the whole picture are often subtle and intangible. The student who previously has been subject to strong religious influences and interests has no time in which to continue developing this aspect of his life. He is so concerned with the means of becoming a doctor that he has little time to consider the ends toward which he is working.

The "Principles of Medical Ethics of the American Medical Association" strikes the keynote of what these ends should be. The introductory paragraph, entitled "The Physician's Responsibility," states:

A profession has for its object the service it can render to humanity; reward or financial gain should be a subordinate consideration. The practice of medicine is a profession. In choosing this profession an individual assumes an obligation to conduct himself in accord with its ideals.

The doctor's responsibility is to solve the patient's problem or to help him solve it himself. This means that he must first understand the patient. To understand people he must be genuinely concerned about the welfare of individuals; he must have a profound respect for human personality. It cannot be denied that his work is predicated on the recognition of the worth of human personality. He is interested first in people, only secondarily in disease; he treats diseases only that men may live more comfortably, more effectively and more abundantly.

Physical maladjustment and disease cannot be separated from one's personality as a whole. The modern physician must treat the whole person. To the doctor who is interested in solving the problems of his patients, a sound, consistent, well rounded philosophy is as essential as a knowledge of pathology and therapeutics. If he is to understand fully the patient's problem, he must understand the mental and moral as well as the physical conditions related to it.

CAN A STUDENT'S ATTITUDE BE INFLUENCED?

In considering these changes that occur in character during the four years in medical school it might not be misleading to compare this to the treatment of tetanus with antitoxin. A certain number of these patients will get well and a certain number will die regardless of the treatment or the lack of it. However, with adequate treatment a number will recover who would otherwise die. So it is with character development in students. Some will have high ideals and keep them regardless of the peculiar situations presented by medical education. A few show little or no possibility of responding to humanitarian influences. In between is a large group which will be definitely influenced for good or bad by the many factors surrounding medical students.

The direction of this change is strongly influenced by intangible forces which go to make up the atmosphere of the school. This thought is clearly expressed in the following statement by Dr. Reginald Fitz, of Massachusetts Memorial Hospitals:

Medical schools, like people, have their personalities. The factors influencing ethical concepts and ideals among medical students depend in large measure on the personality of the school where the student works. This in turn largely is influenced by the character and ideals of the teachers and the spirit of the school. What public opinion says shall be done or shall not be done in a given school, the manner in which the fascination of medicine is presented to the student body, and various other currents of thought are what set the pace in the medical schools for which I have most respect.

The thinking and behavior of the student are influenced to a great extent by the group in

which he finds himself. All too frequently the tone of a school is set by a loud minority who are seeking to impress their fellow students with their lack of inhibitions and restraint. This eloquent minority is so quick to express itself that many important issues are sidetracked by ridicule, and intelligent consideration of them is precluded by a superficial atmosphere. In most cases these students are not conscious of the influence they are exercising. There is a natural reluctance to give any suggestion of a "better than thou" attitude. In fact most students bend over backward to avoid this. They carefully refrain from making any remarks that might be interpreted as idealistic or humanitarian, and yet the greatest heritage of our profession is the tradition laid down by the unselfish lives of great doctors. The action of the minority referred to is not premeditated—it is usually the extroverted expression of inadequate personalities. These students are talking big and bold to bolster their ego. Unfortunately, in so doing they frequently set the whole atmosphere of a school. We are all tremendously affected by social approval or disapproval. There is a strong desire to fit in with the popular conception of what students are supposed to do and think.

Chapters of the Association of Medical Students have a great opportunity here. They are open to all medical students and should serve as a rallying point for those students who have a concern for the moral and social aspects of medical training. They can create situations in which careful consideration of fundamental principles is appropriate. This will lend dignity to discussions of social and humanitarian issues. Group activity may thus relieve the individual of the seemingly unpleasant role of appearing to have ideals above those commonly accepted.

INFLUENCE OF TYPE OF RECREATION

Traditionally, medical students tend to feel that, by virtue of their peculiar situation, of the strain of study and the closeness to the mysteries of life, they deserve license for certain freedom which in others might not be so respectable, such as getting drunk after an anatomy exam. The types of recreation a student learns to enjoy have a subtle and very real influence on his attitudes. If selfish indulgence is his method of relieving tension, the same spirit may carry over into his whole outlook toward his work. On the other hand, relaxation by turning to some different but nonetheless constructive pastime develops habits which will insure a life of greater cultural value and more lasting pleasure. If he takes time for the development of hobbies that are worth while he will find opportunities for expanding his creative abilities and will not feel so keenly the pressure of the

constant grind. No apology need be made for the idea that it is desirable to learn to relax without attempting escape from reality.

The development of friendship offers opportunities either for mutual trivial wasting of time or for constructive common interest in commendable pursuits. There is no reason why friendships on the basis of sports, music, reading or serious discussion cannot be as enjoyable and satisfying as those confined to poker, jokes, liquor and sex indulgence. If adequate facilities for wholesome recreation are easily accessible, the mere factor of convenience may determine the habits of students.

Fraternity life can be one of the most wholesome influences in a student's career. Association with the other men affords an opportunity to understand people better and often leads to helpful, lifelong friendships. Informal contact with prominent alumni helps keep the student in touch with inspiring men of the profession. Under the stress of the medical school routine, the temptation is great for fraternity groups to forego the opportunity of making the fraternity atmosphere as constructive as it might be.

INFLUENCE OF MEN IN THE PROFESSION

One of the strongest influences to which a medical student is subject is the example set by other physicians, both the great men of medicine of the past and those who are still living. Many students enter medical school because of their desire to emulate some respected doctor—often the family physician or a close relative. Many receive their inspiration from the biographies of great men.

The expense of a medical education has frequently caused the student to obligate himself financially so that on entering practice he feels that his first duty is to earn enough money to repay his debts and to declare his economic independence. The high cost of equipment for adequate medical practice, office expenses and the keen competition for pay patients tend to force the young doctor to place primary consideration on the commercial aspects of his practice. This phase of the practice of medicine, distasteful to many yet difficult to circumvent, may cause many students, as they begin to see the profession from the inside, to lose faith and to subordinate their motives of service. This influence may be greater during the first few years out of school than actually in school. This disillusionment is unfortunately increased by occasional contact with those unscrupulous practitioners who exploit their patients and abuse their professional privileges.

Offsetting these undesirable influences are the examples of those splendid physicians who find, in their desire to serve, something bigger than themselves in the light of which petty selfishness

fades. Their common interest in the welfare of men leaves no room for jealousy and antagonism. Realizing that no amount of high motives takes the place of hard work, they constantly study to keep abreast of new developments and seek to make some original contribution to the common store of knowledge. Aware that their task is keeping people well, they stress more and more the importance of preventive medicine. No longer seeking to make a mystery of their profession, they teach the truth they know that people may keep themselves well. These are men of broad horizons: horizontally they have a world view; vertically they think in terms of future generations.

The inspiration of these men strengthens the student's determination to consecrate the best he has to the highest he knows. Progress in this adventure varies with individuals. Some feel that a humanistic philosophy affords an adequate basis; some find in the teachings of Christ the highest concept of the meaning of a life of service. Whatever his philosophy or whatever the basis of his motivation, the student finds conscious effort necessary to continue development. Those who are preparing for this life of service will do well to give considerable time to the conscious development of those attributes of character which embody the ideals implied in a profession of service.

Comments and Reviews

THE ENTRANCE INTO MEDICINE

Abridgment of an address by Hugh Lett, president of the Royal College of Surgeons of England, in the British Medical Journal June 10, 1939.

When I became a student, forty-five years ago, the medical curriculum was very different from what it is today. X-rays and radium had not been discovered, abdominal operations were few, the surgery of the brain and thorax was rudimentary; nothing was known of vaccines, vitamins or hormones, little of blood diseases, and the work in clinical laboratories was confined to the simplest examinations. There were no antepartum departments or special departments for diseases of children or infant welfare or for orthopedic, genito-urinary or chest surgery, to mention only some of those there are today.

FUNDAMENTAL PRINCIPLES

Although much more is now known about every branch of medicine and there is much more to learn, the fundamental principles of medical education are the same. Now as then there are things that must be known, some that ought to be known, and others with which the student should have some acquaintance if only to satisfy examiners. That is not all, for in addition to acquiring medical knowledge the student is taught to cultivate accuracy, observation and deduction and to reason carefully, so that he may be able to bring a trained intelligence to bear on medical problems.

Medical education should mean much more than the acquisition of so many facts and theories; it should train the mind in such a way that it may be ready to take the initiative, to adjust itself quickly to new situations, to apply to each case in an understanding way the principles, the routine, the discipline which have become second nature. The years spent as a

medical student are only an introduction to a study which must continue throughout professional life.

THE PRECLINICAL YEARS

You may feel impatient at the time that must elapse before you reach the wards and come into contact with sick people. You may feel that the time given to chemistry, physics and biology, and a great part of what you are taught in anatomy and physiology, are quite unnecessary; yet these subjects have a very important bearing on clinical work. A preliminary knowledge of them is essential if you are to understand the methods of examining patients, and certain forms of treatment.

We owe much to physics, first of all the x-rays, which are of immense value in the diagnosis of disease, and radium, which like the x-rays has done much for inoperable cases of malignant disease. Physicists discovered the ultraviolet rays, which play an important part in the demonstration of ultramicroscopic viruses. I need hardly refer to the importance of electricity. Before long the method of electro-encephalography will enable us to determine the exact site of a tumor lying deep in the brain. Lastly, we must not overlook the developments of optical instruments by which we can see the interior parts of the body.

Biochemistry has taught us about vitamins and the vital importance of the secretion of the ductless glands and has given us many remarkable drugs which have revolutionized the treatment of a number of diseases, so that with the help of these drugs we expect recovery in many cases which formerly would have been regarded as hopeless.

Much of the valuable experimental research that is being done today could never have been attempted had it not been for the advances that have been made in physics and biochemistry.

And so, if we recognize how much medicine and surgery owe to them, it is not difficult to understand why physics, chemistry and biology form the first part of the education of the medical student.

Anatomy and physiology teach us the structure of the normal human body, the functions of its various organs and the part they play in the life of the healthy individual. It is obvious that we must have a clear understanding of the body in health before we attempt to recognize the changes that take place when it is diseased and before we can understand why these changes give rise to the various symptoms and signs that show illness and disordered function.

An important advance in medical education was made recently when it was decided that while the student is still working at anatomy and physiology he should be taught something of the elementary principles of medicine and surgery and learn certain methods of examination which previously were taught only in the clinical years. This elementary clinical instruction helps one to appreciate more clearly the importance of anatomy and physiology, for the gap that previously existed between them on the one hand and medicine and surgery on the other is now bridged, and they are no longer treated as independent parts of the curriculum.

THE CLINICAL YEARS

When you reach the wards and begin clerking and dressing, you will find that among other duties you have to take histories of patients. A good history includes an account of the patient's illness and his previous health, his present symptoms, and finally a description of what you have been able to discover after careful examination not only of the part that is principally affected but of the whole body.

I remember a student who said that he really did not see why he should spend his time taking notes for the benefit of the hospital. I may say, perhaps, that from my recollection of his notes any benefit that the hospital could have derived from them was remarkably small. But he was approaching his work in the wards from the wrong angle. It did not occur to him that the taking of histories was an important part of his education. Careful, systematic note taking and a routine examination of the whole body in every case will teach you method, develop your powers of observation and impress the details of cases on your memory. The importance of examining the whole body is sometimes overlooked, and the omission has been followed by serious results.

Do not be too much afraid of making mistakes. We all make them; but if we make mistakes in spite of having exercised care and thought, and if when we have made them we try to find out where our reasoning or observation

was at fault, we may learn more from our mistakes than from our easy or sometimes fortunate successes.

Try so far as possible to make a preliminary diagnosis before the results of the x-ray examinations and the clinical laboratory tests are available. In many obscure cases such a diagnosis will not be possible; nevertheless it is a sound practice to try to make it. Some day you may be in such a position that these examinations cannot be made, and you may have to make a diagnosis when you and your patient are far from an x-ray apparatus or a clinical laboratory. But an even more important reason for following this method is that by doing so one acquires keener powers of observation, reasoning and deduction. The rapid progress made in medicine and surgery has brought a certain danger in its train: the possibility that too much reliance may be placed on the result of tests in the laboratory and examinations in the x-ray department at the expense of careful clinical examination. This can never be replaced.

A full and careful study of the patient, body and mind, is the essential foundation on which our healing art is built. The training of our students must be directed above all to the cultivation of careful clinical observation and an understanding and appreciation of signs and symptoms. In this way only can they acquire that vital yet intangible something we call clinical instinct. Clinical instinct, born of observation, must and always will remain one of the greatest and most important gifts a medical man can have.

THE APPROACH TO THE PATIENT

It is remarkable that in the past the medical student should have received so few hints on the attitude to be adopted toward patients, the way to approach them, to manage them, to obtain their confidence. On entering practice he has had to rely on his natural gifts and instinct, or perhaps, if he has been fortunate, on his ability to copy an admired clinical teacher. And yet the importance of understanding the patient and appreciating his mental condition and outlook has long been recognized, even by laymen.

The introduction into the curriculum of psychology and some knowledge of the psychoneuroses and of the important part the mind plays in good and bad health should be a help to both doctor and patient. But the physician who in the approach to his patient cultivates sympathetic understanding, cheerfulness and confidence may be said to have acquired already the fundamentals of bedside or consulting room psychology.

Sentimentality must of course be avoided, but if you can develop a sympathetic understanding of your patient's anxieties and difficulties you

will find that you can help him greatly. You will be able to do much to reassure him, to remove great and little discomforts, both physical and mental.

A quiet cheerfulness is a great asset. The gloomy physician "maketh the sick man sicker." Sir Benjamin Brodie said that it was a good rule in the practice of an art, as in the common affairs of life, to look on the favorable side of the question so far as it was consistent with reason to do so. But the cheerful attitude does not mean that aggressive, bouncing cheerfulness which can be so very irritating, especially to the sick man. If you should be anxious about your patient, try to conceal your anxiety and remember that while you are making your examination and talking to him he will be searching your expression to learn whether you really believe in the assurance you are trying to give him.

Confidence can come only with experience and hard work, by learning from what you have seen and read, and by thinking over the reasons for your successes as well as your mistakes. Nothing is more ugly than conceit or vanity, but they are very different things from that confidence in which, said the prophet of old, shall be your strength.

SHOULD STUDENTS MARRY?

Slightly abridged from an article by C. C. Gibbons in the Surgeons' Hall Journal of June 1939, which journal is published by the students of the School of Medicine of the Royal College of Physicians and Surgeons, Edinburgh, Scotland.

It was with mixed feelings that I left the *Journal* office with the assignment to write, to say the least of it, a controversial article. In fact, every time I thought of it I found myself bemoaning the fact that I ever joined the writing staff of the *Surgeons' Hall Journal*. . . . However, I had to tackle it. . . .

Interviewing the married students was an "interviewer's paradise." They seemed surrounded by an air of contentment; their powers of concentration when dealing with questions were infinitely greater than that of the unmarried student, who seemed eager to leave me high and dry whilst they went dashing after some trivial pleasure or imaginary errand; I had to force them into a corner and make the wildest promises until the answers to my questions were squeezed out of them.

The married students were definitely in favor of marriage for students. All claimed to a more settled attitude toward their work after marriage than before. I inquired as to what they attributed this and they all gave the same response, that their needs were satisfied, bringing a greater cohesion in their psychologic make-up.

"But what of the financial side of things?" I asked. Well, the general view was that, if you have a wife who shows consideration toward your position and is ready to forego some of the luxuries and also cooperate in a responsible plan of domestic economy, the chances of an unhappy struggle are remote. The fact that the prospects of the future are bright, and by complete cooperation between student and wife that future can be realized, was an incentive to both and a definite encouragement to them in these days when the question of marriage was being discussed and weighed in the balance.

"Don't your wives find at times that as students you are difficult to live with?" "Of course," was the general reply to this question, "they realize the strain of prolonged study, the anxiety of approaching examinations and the deplorable system of medical education, with its cram and absurd academic demands. Prior to marriage they knew us, and we haven't changed for the worse. Anyhow, lawyers, doctors and clergy are often difficult to live with, even plumbers, taxicab drivers and clerks." I asked: "How much do you think you need to marry on?" Here I found a difference of opinion, but all agreed that 3 pounds 10 shillings a week was sufficient, provided you had a little capital behind you or a guarantor. I then asked my last question: "Didn't your parents object?" "At first they were antagonistic toward the idea, but eventually they realized our point of view and have come to regard our marriage as a sound investment rather than a liability. For, after all, why should a student be denied the advantages of a wife and home simply because he has taken a course of study extending over the best years of his life?" To the younger students this does not apply, but to the older students it has a definite and real meaning.

I came to the conclusion that married students were definitely at an advantage, and not only was there an air of confidence about them but their academic performances in relationship to examinations proved conclusively that marriage aided better results rather than the contrary.

The single students talked of economic difficulties—the fact that they must provide a home of idealistic luxury seemed to worry them. Their ideas regarding a standard of living was influenced by a lack of experience—indeed, to one of them, 10 pounds a week was a mere pittance. I hid my smile, raised my hat and wished him luck. He doesn't realize that the majority of people today in this country are living on nearer 2 pounds a week than 3 pounds a week, with little prospect of more. From even the single students there was little or no opposition to students marrying provided, they

all agreed, you find the right partner and not one who would prove an encumbrance.

I felt rather disappointed that I hadn't found any one with real objections. Perhaps you have? Then write a letter to the editor and let him print your objections. After all, there are two sides to every question.

STUDY OF ACCOMPLISHMENT OF THE 1937 FRESHMAN CLASS

Abridgment of an article by Dr. Fred C. Zapffe, published in the Journal of the Association of American Medical Colleges, May 1939.

A study of the accomplishment of students enrolled in the freshman class of the seventy-seven medical colleges in the United States and eight in Canada which participate in the study by furnishing the information on which it is based has been made since 1928; therefore the data presented herewith constitute the tenth report.

The total number of students reported on by all medical colleges at the end of the academic year 1937-1938 was 5,994. There has been a steady reduction since 1934-1935, when 6,683 freshmen were reported. Of the 12,128 students who applied for admission to the 1937 class 7,543, or 62.1 per cent, were accepted. . . . The accomplishment of those enrolled was as follows: clear, 75.4 per cent; encumbered (subject conditions or failures or both), 12.7 per cent; must repeat, failed, dropped, withdrew because of poor or failing scholarship, 8.9 per cent; withdrew on account of illness, lack of sufficient finances or reason not given, 2.9 per cent. This gives a percentage of 11.8 of all freshmen who were not promoted to the sophomore year, assuming that all those with subject conditions or failures succeeded in removing them and subsequently entered the sophomore year. These results are a distinct improvement over those of the 1936 class.

A study of the degree of preparation of these students discloses interesting facts. First, there is an increasing tendency for prospective medical students to remain in college longer. Whether this should be ascribed to a desire for better preparation or to a belief that it will help to secure admission to a medical school is a question. But when the better accomplishment is taken into consideration, one is almost forced to believe that students remain in college longer to be better prepared for the study of medicine. Of the 1937 class, only 6.55 per cent had less than three years of college work. The number of students holding a bachelor's degree or better was larger than in previous years, 55.75 per cent. Each year those with lesser preparation have diminished in number, whereas the degree holding group has steadily increased in numbers. The group with three years or more of

preparation but less than four years has remained fairly constant. In 1937 the percentage was 32.3. The four or more years group not possessing a degree has also remained constant, 5.4 per cent in 1937.

The four or more years group is definitely a hazard. Although some members of this group have attended college for as many as eight, even nine, years, they do not seem to have the right preparation, aptitude or attitude for the study of medicine. Perhaps one should regard too many years in college as an indication of unfitness for the study of medicine. True, the group is not large, 333 in 1937. They make the poorest showing on all counts of any group.

It is quite evident that students are beginning to appreciate that it is wiser to take the courses of study which lead to the bachelor of arts degree than those which lead to the bachelor of science degree. The cultural courses of the long ago are coming into their own again.

The women students numbered 341 in the 1937 class. The women do not do as well as the men. Despite more preparation, they had fewer clear records, more encumbered records, more failures and more withdrawals.

The total number of women students in all four years in 1937-1938 was 1,109 as against 20,538 men students, or 5.4 per cent. At the end of the year 1937-1938, 253 women received the degree of M.D. Included in this total are women who completed their college work in June 1937 but were not eligible for the degree of M.D. until after the completion of a one year internship.

Some medical colleges will not allow any student to repeat; others do. Every year there is a considerable number of repeaters. In the 1937 class there were 198 repeaters, 3.6 per cent of the total number of freshmen. Thirty-five of these repeaters failed again and ten withdrew; in reality, only seventy-two of the 198 repeaters justified their acceptance.

Of the 1937 class, 79.2 per cent took the medical aptitude test. Each year more and more students who are thinking of entering medical school take this test. Even if a student does not intend to study medicine, the test is a fine thing to take because it helps to show him where he is weak and where he is strong so far as knowledge and aptitude are concerned. Perhaps too the test helps to bring about a change of mind by convincing a student that he should not study medicine. In either case it is worth while.

DATA FOR CANADA

In proportion to population, Canada has at least as many medical students as we have, if not more. The ten Canadian schools graduated 572 students, about 11 per cent as many as our own medical schools graduated. Many of that group are citizens of the United States who for

some reason or other studied medicine in a Canadian medical school. McGill has always had quite a number of students from the United States. Most of the Canadian schools do not accept any students from the United States.

MENTAL HYGIENE PROBLEMS OF THE COLLEGE STUDENT

Abridgment of an article by Dr. Harry M. Tiebout published in Preventive Medicine, November 1938.

There are certain standards of behavior in the college setting which are generally accepted as valid evidence of normal or satisfactory adjustment. If the student (1) on the health side keeps relatively free from sickness, (2) on the educational side does the required work adequately, (3) on the vocational side sticks to his courses without too much scattering or shifting, (4) on the personal side manages his relationships with his teachers and classmates with fair success and (5) on the mental side displays no serious oddities or quirks of behavior, then he is considered to be a normal member of the college community. Within each of these five categories there is admittedly room for wide variation but, without getting into argument as to when that time comes, in each of these groups there does come a time when the extent of the variation is sufficient to warrant the feeling that the individual is deviating significantly from the usual pattern and is in need of help. College people accept without question the need for a healthy body as a prerequisite for successful educational progress. They believe that adequate sleep, proper diet, sufficient exercise and regular living are essential to the maintenance of health and they do what they can to foster these beliefs in the student group. Furthermore, the well equipped college can handle with reasonable satisfaction run of the mill physical ailments which constitute a majority of infirmary calls. There are, in addition to those with a demonstrable physical condition, other students who frequent the infirmary complaining of many symptoms, yet suffering from no definable physical malady. They correspond to a similar group found in practice and offer interesting points for psychiatric study. They are the so-called neurotics.

The neurotic group may be divided into two types: (1) those suffering from out and out neuroses and (2) those having a condition less easily defined but constituting a perplexing diagnostic problem in which organic and functional elements coexist. The symptoms of the neurotic group are usually cardiac or gastric in nature. There is probably nothing unique in the neurotic manifestations that show themselves in

college life. They seem to appear during the stress of new adjustments associated with entering college and perhaps are more than customarily prone to be marked by a physical symptomatology. Their treatment differs in no essential way from their treatment in other surroundings and is, as a rule, more successful.

EDUCATIONAL DEVIATIONS

Failure on the part of the student to progress in accordance with his level of ability is now considered a problem of mental hygiene. The well equipped college recognizes the fact that students vary widely in capacity. They are given psychologic tests and they are not expected to progress at a speed faster than the capacity indicated by their test scores. If the test score indicates that the person's rate of progress will be below the minimal standard for the particular college, he or she is not admitted as a student. This does away with the old hit or miss practice in which the college sifted out the good students by flunking the poor ones, giving no thought at the time to the feelings of the students who flunked. Nowadays, when a student fails, the question automatically arises "What is interfering with his work?" Often the interfering factor is readily discernible; a complicated home situation, poor health, financial stringencies, or a girl or boy problem may prove to be the distracting element.

VOCATIONAL DEVIATIONS

What the normal attitude of the young person in college toward his vocational choice is is open to question. While I do not believe that the student in his teens should be utterly aimless in his thoughts about his vocational future, I doubt the normality of the student who, from childhood, has been fired by a burning desire to be a something or other. Such zeal is apt to rest on compensatory foundations and not necessarily on worthwhile abilities. In my experience the greater proportion of students find the present pretty satisfactory and generally think in terms of it. Too much concern about the future leads to doubts and hesitations about the present and a lessening of scholastic effort and accomplishment.

PERSONAL DEVIATIONS

The college today is taking cognizance of the fact that its responsibilities for the individual student extend beyond the student's successful absorption of knowledge to the indefinable field of personality development. The unhappy student, the lonely, withdrawn student, the rebellious student, the lovesick student all call for help. Their problems, if allowed to continue unnoticed, may interfere with their obtaining the maximum benefit from college experience.

MENTAL DEVIATIONS

Aside from the neuroses, problems of outright mental deviation do not bulk large on the college horizon. There is the occasional early schizophrenic development, the relatively rare frank depression or excitement, the occasional suicide. Delinquencies also are rare, although epidemics of stealing occur, the offender or offenders needing psychiatric attention when apprehended. The alcohol problem is a constant source of concern, not because it involves a large proportion of the student body but because the alcoholic student stands out like a sore thumb. In treating the relatively rare case of alcoholism, it is assumed, rightfully, I believe, first, that there is a psychologic factor at work which causes the resort to drinking and, second, that as a consequence of the first assumption the problem can best be managed by removing the causative factors through psychiatric treatment. With this group, detection of the serious cases is the chief function of the college psychiatrist. I want to bring the general practitioner into this picture. Where does he function in a college mental hygiene program? For two reasons he has an inevitable advantage over the school. First, he has known the individual student for a long time and, second, he has the confidence of the family, who will take his advice far more readily than that of a new physician. Every practitioner fully appreciates how often he has an advantage over the psychiatric specialist when it comes to diagnosing a case in which long contact with a patient and his family affords a background of understanding far more helpful in sizing up the individual than hours spent in gathering the case history. This being the situation, it is unfortunate that the general practitioner passes on so little of this information to the college in the questionnaires supplied by the student health department immediately prior to the student's admission to college. I wish it were possible to impress on the family physician how pleased the school is to receive a thoughtful report from a student's doctor, how carefully it safeguards such material and how much more secure it feels about going ahead on a constructive program for the student. Again, the family doctor occupies a more effective position than the school with the student's family. In the treatment of nervous troubles it is a truism that, unless the cooperation of the family can be secured, therapeutic efforts are wellnigh hopeless. If the family physician puts his stamp of approval on the suggested treatment, the family is likely to cooperate more wholeheartedly.

A school mental hygiene program therefore must rely to a very considerable extent on the family physician.

COMPILATION OF COURSES OFFERED IN HIGH SCHOOLS

The Office of Education of the United States Department of the Interior has made a vast compilation of courses¹ offered and students registered in the high schools of the United States. The authors say that more time and effort are given to English than to any other subject field. Social science is second in curriculum emphasis but is a considerable distance behind English. Commercial work and science are found close together in third and fourth places. Physical education is also in close proximity if it is allowed to borrow hygiene and sanitation from the science group of studies. Sixth place belongs to mathematics, seventh to foreign languages as a group, and eighth to music. Mechanical drawing holds the balance of power for the next three positions; if it is given to drawing and art, that field is in ninth position; if it is given to industrial and shop subjects they take ninth place and, if it is assigned to neither of these, home economics steps into ninth place. Of the subjects here treated, agriculture is in last position. That English stands first is interesting in the light of the dictum of President Hutchins that most college graduates can neither read, write, speak nor think.

GROWTH OF THE BOSTON CITY HOSPITAL

The present great institution with many departments, clinics and offices seems far removed from the unpretentious beginnings of the Boston City Hospital in 1864. The hospital has treated more than a million patients. While Boston ranks ninth among the cities of the United States in population, the Boston City Hospital ranks fourth in the number of patients treated. Its growth in size has been less remarkable than its progress in the character of service rendered. In 1870 the patient remained in the hospital an average of twenty-seven days, whereas the corresponding figure now is eleven days. A recent article by Merrill Moore² shows that the death rate has declined from more than 13 per cent in 1894 to less than 7 per cent in recent years. In fostering the scientific spirit of the medical staff and in definitely assuming an educational responsibility, the Boston City Hospital has won a reputation which attracts students and physicians from all parts of the world.

Medical College News

Medical schools, hospitals and individuals will confer a favor by sending to these headquarters original contributions, reviews and news items to be considered for publication in the Student Section.

Students Who Hold Harvard's National Scholarships

The three outstanding candidates for admission to Harvard Medical School, Boston, this fall as recipients of national scholarships offered by the school are Louis E. Ward, Mt. Vernon, Ill.; Samuel R. Ginsburg, Passaic, N. J., and Allan L. Friedlich Jr., New York. This is the third year of the school's national scholarship plan. The three students who received the awards in the freshman class of Harvard Medical School last year have maintained honor records and have had the stipends renewed for the remaining three years of their medical studies. They are Glen R. Leymaster, Aurora, Neb.; Clarke T. Case, Pymmana, Burma, India, and Laurence G. Wesson Jr., Boston.

The three students who won the Harvard national scholarships in the first competition and who are now entering their third year of study at the medical school are Ward S. Fowler, Eldora, Iowa; Carl C. Gardner Jr., Columbia, Tenn., and William F. Loomis, Tuxedo Park, N. Y.

The Tower Club at Ohio State University

Faced in 1933 during the financial depression with the loss of many worthy students, Ohio State University undertook to help them by providing a dormitory in one of the towers of the university stadium, where only \$3 was charged for room for the academic year and \$2.75 a week for board.

The three upper floors of the Tower Club provided sleeping quarters; on the first floor were the dining room and kitchen. There were showers, lockers and a game room; the dining tables later were used for study facilities. The university provided beds, mattresses and pillows. Men live in rooms or rows accommodating from fourteen to forty-two, each with a floor captain who is responsible for the cleanliness and discipline of his group. The students do all the work except the cooking. Their personal laundry is usually mailed home. Students are rated on the kind of work they do in the dormitories, and permission to remain in these groups depends on the scholastic and conduct records established, including the performance of dormitory work. The Tower Club became so popular that an extension had to be built the following year, using space in a section of the stadium adjoining the tower and under the stadium bank seats; still other units were added until their capacity reached 800. There is an esprit de corps that characterizes the personnel of these dormitories. The Tower Club men wear a button indicating pride in membership. There are several times as many candidates for these dormitories as there are places for them. Admission is open to Ohio students only on the basis of scholarship, character and financial need.

Yale Plans to Expand Medical School

A committee has been formed to publicize the work of Yale University, New Haven, in medicine and health as a step toward the establishment of a program to obtain funds for expansion. Dr. Harvey Cushing is general chairman and Dean Stanhope Bayne-Jones, chairman. Other members of the committee include: Fuller F. Barnes, Bristol, Conn.; William McCormick Blair, Chicago; George Parmlly Day and Thomas W. Farnam of Yale; Dr. Norman E. Freeman, Philadelphia; Harry C. Knight, New Haven; Fred T. Murphy, Detroit; Charles Edward A. Winslow, Dr. P.H., and Dr. Milton C.

Winternitz of Yale. The committee's efforts will be turned especially toward alumni and close friends of the university. According to the *New York Times*, a doubling of the school's endowment for medical education and research is sought. Capital is sought to provide annual income now furnished by grants, especially in the department of psychiatry and mental hygiene and the clinic of child development. In addition to providing training for general practitioners, the school plans to increase opportunities for the education of specialists in fields of surgery, medicine and public health. Desirable additions to the physical plant of the school include a building for the library and an auditorium.

Thirteen Students Win Crile Awards

The thirteen students at Western Reserve University School of Medicine, Cleveland, who have been awarded Crile Scholarships for research during the coming year, according to dean Torald H. Sollmann, are: Robert R. Berneika, Joseph Dimont, Edward W. Shannon, Daniel A. Brody, Roger K. Kalina, Joseph Kovacs Jr. and Aaron Paley, all of Cleveland; Salvatore M. Sancetta, Cleveland Heights; Edmund F. Schroeder, Shaker Heights, Ohio; John M. Cook, Basil, Ohio; Joseph Selman, Albany, N. Y.; Jay R. Wells, Parkersburg, W. Va., and Louis G. Ralston, Lakeland, Fla.

Loan Funds at Cornell

The Cornell University Medical College, New York, administers the 1923 Loan Fund, which amounts to \$400 a year and is available as a loan to a student needing financial assistance, preferably to a third year student. The college administers the alumni association loan funds and also the Student Loan Fund, a revolving fund founded by students in the medical college and available to members of the third and fourth year classes.

There is also at Cornell a number of scholarships available to students, which are awarded, however, primarily on merit, with need a secondary consideration; also prizes for general efficiency in certain departments. Three prizes are awarded for efficiency in gynecology to members of the senior class in the order of merit. These prizes, \$125, \$75 and \$50 respectively, were established by Mrs. W. M. Polk in memory of her husband, who was dean and professor of gynecology for many years preceding his death in 1918. Application should be made to the office of the dean.

Tuition and Other Fees at Cornell

The tuition fee at Cornell University Medical College, New York, is \$500 a year, and an advance of \$100 on account is required of all applicants accepted for admission. There is also a matriculation fee of \$10 payable on admission, a special obstetric fee of \$10 payable at the beginning of the third year and a fee of \$25 payable on registration for graduation. There is a breakage deposit fee of \$10 required of all first and second year students at the beginning of each academic year, but this will be returned, less the amount charged for breakage, at the end of the year. All students entering the college must have microscopes and later hemocytometers and hemoglobinometers. The average cost per year for books is estimated at \$75, according to the last available announcement of the medical college.

Honor Students at University of Maryland

At the commencement of the School of Medicine of the University of Maryland in June in Baltimore, graduate James Baker Nuttall was awarded the University Prize Gold Medal and Graduate Leonard Wallenstein was awarded the Dr. A. Bradley Gaither Memorial Prize of \$25. Certificates of honor were awarded to Francis J. McLaughlin, William H. Leitch, Leland B. Stevens, Raymond M. Cunningham, Thomas S. Sexton and Ramsay B. Thomas. The commencement address was delivered by Herbert R. O'Connor, governor of Maryland.

Annual Dinner at Jefferson

The annual dinner of Jefferson Medical College of Philadelphia was held June 1, 1939, at the Bellevue Stratford Hotel with 500 alumni in attendance. Dr. Henry K. Mohler, dean, presided. The speakers were: Mr. Robert P. Hooper, Philadelphia, president of the board of trustees; Dr. Randle C. Rosenberger, professor of preventive medicine and bacteriology, Jefferson Medical College of Philadelphia, representing the class of 1894; Dr. David B. Allman, Atlantic City, N. J., representing the class of 1914; Dr. Jean-Louis E. Brindamour, San Francisco, representing the class of 1924; Dr. Albert J. Winebrake, Scranton, Pa., representing the class of 1899; Dr. Edmund L. Jones, Wheeling, W. Va., representing the class of 1919; Dr. John W. Gahan, Medford, Mass., representing the class of 1929, and Dr. Paul A. Kennedy, Philadelphia, representing the class of 1939.

Scholarships at Baylor University

Baylor University College of Medicine, Dallas, Texas, has a limited number of scholarships and loan funds for the purpose of encouraging and aiding medical students. The Round-Up Publications Board of the University has established a loan fund consisting now of about \$3,000 from which limited loans may be made to senior students. The national fraternity for medical women, Alpha Epsilon Iota, has a loan fund contributed by its members for the purpose of assisting women medical students in advanced classes. Information about this fund can be obtained from the local chapter president. The income from the Dr. J. H. McCorkle Memorial Scholarship Fund is given each year to some medical student designated by the college authorities and the donor. The income from the A. P. Cary Scholarship Fund of \$2,500, held in trust, is given each year to some medical student designated by the president of the university. The total amount of tuition and fees for the first year at Baylor University College of Medicine is \$414. This sum, of course, does not include board, room, clothing, transportation and the like.

Prize Winners at Western Reserve University

Jacob B. Tuckerman, son of Dr. Jacob E. Tuckerman, was a double prize winner in the recent commencement awards of the medical school of Western Reserve University, Cleveland. To him were awarded the senior prize in surgery, the gift of Dr. Elliott C. Cutler, Boston, and the senior prize in obstetrics, gift of the late Dr. Edwin C. Garvin, Cleveland. Roswell Wenner Machamer was awarded the Dr. Herbert S. Steuer Memorial Prize for special work in anatomy.

Student Officers at Louisiana

Taliaferro H. Gaharan, Jena, La., has been elected president of the student council of the Louisiana State University School of Medicine, New Orleans, for the current year; Marion J. LeDoux, New Orleans, vice-

president, and James M. Pomeroy, Bastrop, La., secretary and treasurer. William R. Hargrove, Oakdale, La., was elected president of the class of 1940; Burdette E. Trichel, Harrisonburg, La., president of the class of 1941, and Keith A. Stratford, Ogden, Utah, president of the class of 1942. Leslie L. Parker, Opelousas, La., was made president of the interfraternity council and Spurgeon M. Wingo, New Orleans, editor of the *Tiger*, the student weekly publication.

Northwestern's New Dormitory for Students

Northwestern University has under construction at Huron Street and the Lake Shore Drive in Chicago a new eighteen story building which will be used exclusively as a dormitory for medical, dental and

Eighteen story dormitory of Northwestern University.

law students. The dormitory will have on each residential floor single and double rooms to accommodate sixty students, while the entire structure will accommodate 700 students. There will also be in the building libraries, dining rooms, lounges, exercise facilities, shops and a roof garden. The rentals will average around \$180 a semester. The building, in modified Gothic style, will be built of Indiana limestone, to conform with the seven other buildings on the Chicago campus of Northwestern University. Two thirds of the rooms in the new dormitory will have a view across Lake Michigan. A bathing beach will be available just across Lake Shore Drive.

Annual Award at Wayne University

Dr. Jacob A. Sill, 1939 graduate of Wayne University College of Medicine, Detroit, received the annual award of \$50 for the best general rating during the four year course at the school. The award was made at the annual dinner of the graduating students, faculty and alumni June 15, on which occasion Major General Merritte W. Ireland, formerly surgeon general, U. S.

Army, gave the principal address. Dr. Ireland graduated from this school in 1890 when it was known as the Detroit College of Medicine and Surgery. At the speaker's table was a member of the graduating class who represented the student body.

Scholarships at the University of California

Following are some of the scholarships and prizes open to students at the University of California Medical School, Berkeley:

The Base Hospital No. 30 Scholarship of about \$300 a year, is the income on the balance of a fund collected for the University of California Medical School Hospital Unit, No. 30.

The George Frederick Reinhardt Memorial Fund—Class of 1915—Scholarship, yields about \$190 in the year 1939-1940. Preference is given to a candidate who is the son or daughter of a member of the Class of 1915 of the University of California.

The Sheffield Sanborn Scholarship, of about \$200 a year, is open to medical students who need financial help to finish their training.

The Allen D. Wilson Memorial Scholarship, amounts to about \$110 a year.

Scholarships are awarded only to students who are enrolled in the school at the time of application. Applicants for admission to the first year class may apply for undergraduate scholarships to the Dean of Undergraduates, California Hall, University of California, Berkeley.

THE WOODWARD PRIZES

The three Guy K. Woodward Prizes (first \$150, second \$50 and third \$25) are offered to students in the third and fourth years of the medical curriculum who present manuscripts showing original thought in the field of internal medicine. Manuscripts offered in competition for the prizes must be in the hands of the professor of medicine before June 1 of the senior year.

Estimated Expenses at Columbia University

Following is an itemized estimate of expenses of attendance at Columbia University College of Physicians and Surgeons, New York, for a full academic year, according to the latest available announcement of the college:

	Average	Minimum
Tuition and fees.....	\$530	\$530
Room	235	172
Board	324	216
Books	70	10
Laboratory charges—first year.....	15	15
Laundry	40	28
Additional expenses, including clothing, travel, charity, organizations and sundries	250	150
Total	\$1,164	\$1,151

Aid for Students at Columbia University

Columbia University College of Physicians and Surgeons, New York, has funds available in limited amount to loan to worthy students to assist in their medical studies. Applications should be filed for the spring season by January 15. Columbia University also has available many scholarships and fellowships which have been named after the donor and which are available to aid medical students in research, investigations or postgraduate study in limited amounts. Scholarships are usually awarded only to students who have high academic records and promise. Last year ninety-seven scholarships were awarded. The applications must be made in each year for which a scholarship is desired. Scholars are required to pay the balance of their tuition fees and all other fees.

Columbia University College of Physicians and Surgeons has available also a number of prizes which are awarded under specified conditions. For example, the annual income of a gift of \$5,000, a fund known as the Dr. William Perry Watson Foundation in

Pediatrics, is given in cash annually to that member of the graduating class showing the most efficient work during the course at the college in the study of diseases of infants and children. The Dr. Harold Lee Meierhof Prize, the income of a fund of \$1,000, is available for award by the professor of pathology to the student who he considers has done the best work in that field for the current year.

Conference of Student Societies

The third annual conference of representatives of medical student societies was held in Leeds, England, July 11-14. The general subject for discussion was the prospect for the newly qualified doctor, which was dealt with under five heads: general practice, consultative practice, public health, federal services and research.

Loan Funds at Boston University

Boston University School of Medicine has certain loan funds to be used for the purpose of aiding worthy medical students. There is the Edward E. Allen Fund, the George Russell Fund and the Fenno Tudor Fund, the last established especially to aid women medical students. The university also administers certain scholarship funds which have been named after the donor and are available and awarded annually to students of advanced standing whose industry, ability and need justify the committee making the awards. First year students, except under special circumstances, are not expected to apply for aid. Applications for scholarship aid should be made to the office of the dean of the medical school prior to October 1.

Scholarships at the University of Colorado

Some of the scholarships and prizes available to students of the University of Colorado School of Medicine, Denver, are as follows:

Undergraduate Scholarships. Holders of University of Colorado Junior-Senior Scholarships who enter the school of medicine for their fourth year will be granted a remission of tuition to the extent of \$22 a quarter during their first year in the school of medicine provided they ranked in the upper 25 per cent of the junior class.

The Edward G. Stoiber Scholarship. The Stoiber Scholarship Fund consists of the principal sum of \$2,000 held in trust, the income of which is given each year to some student in the school of medicine designated by the donor or by the officers of the school.

Chester H. Elliott Memorial Prize in Pathology. The annual income from a fund yielding about \$30 a year is awarded to the fully matriculated medical student showing the greatest proficiency in the second year courses in pathology.

Alpha Omega Alpha Prize in Anatomy. The local chapter of this honorary fraternity offers an annual prize of \$25 to the medical student showing the highest scholarship and efficiency in gross and microscopic anatomy courses.

Dr. James C. Todd Prize in Clinical Pathology. The Colorado Society of Clinical Pathologists offers a money prize each year to be awarded to the student who shows the greatest proficiency in laboratory work in clinical pathology.

Carbon Gillaspie, M.D., Memorial Prize in Applied Anatomy. The prize of about \$25 a year will be awarded, on recommendation of the head of the department of anatomy, to the medical student showing exceptional scholarship and technical skill in the course of applied anatomy.

Wisconsin State Board Questions

The following questions in physical diagnosis were given at the examination held in Milwaukee, June 27-30, 1939, by the Wisconsin State Board of Medical Examiners:

(Answer three)

1. What physical signs may be expected in cirrhosis of the liver?

2. What symptoms and physical signs would warrant the diagnosis of complete heart block?

3. What physical signs may be present in aneurysm of the arch of the aorta?

1. Given a patient with frank lobar pneumonia, what change in symptoms and physical signs would indicate the development of empyema?

THE SURGICAL TREATMENT OF PITUITARY ADENOMAS

CHAIRMAN'S ADDRESS

FRANCIS C. GRANT, M.D.
PHILADELPHIA

The surgery of pituitary tumors began in 1906, when Schloffer¹ attacked such a lesion by the endonasal or transphenoidal route. His familiarity with the nasal accessory sinuses led him to select this approach. Subsequently this technic was modified by Kanavel² in 1909 and by Halstead³ and by Hirsch⁴ in 1910. In 1912 Cushing⁵ further modified the transphenoidal approach in minor details and emphasized its value in the treatment of pituitary adenomas by reporting a large series of cases.

However, the disadvantages of the endonasal route, lack of satisfactory exposure, which handicaps the operator, especially if the adenoma is solid, danger of meningitis and the technical difficulties inherent in the procedure, forced the development of an intracranial approach. In 1909 Krause,⁶ in 1913 Frazier⁷ and in 1920 Heuer⁸ described an approach from above through the anterior cranial fossa which, with minor modifications resulting from increasing experience with intracranial conditions, has become the accepted method of attacking any intrasellar or extrasellar tumor.

As early as 1907 the development of the roentgen ray had reached the point where its effect on glandular hypertrophy was recognized. In 1909 Gramegna⁹ reported prompt but unimpaired improvement in a middle aged acromegalic woman following irradiation of the sella through the mouth. In 1922 Bécclère¹⁰ described a case in which a girl with a pituitary tumor had violent headache, visual disturbance and acromegaly. Thirteen years after roentgen therapy her health was perfect with return of menstruation,

improvement in visual acuity and recession of acromegaly. Since that time a number of papers dealing with roentgen therapy of pituitary tumors have appeared, the first large group being detailed by Heinismann and Czerny.¹¹

A summary of the literature on roentgen therapy suggests that of the three types of adenoma now recognized the basophil adenoma is the most susceptible to this treatment, next the acidophil and lastly the chromophobe. Furthermore, experience seems to show that cystic adenomas are less responsive to this therapy than solid. Lastly, there seems to be a general agreement that, since a careful check of the visual fields will show promptly whether or not roentgen therapy is effective, this treatment should be instituted prior to surgical intervention.

An adenoma of the pituitary gland produces two groups of symptoms: first, those related to direct effect on the gland itself, the endocrine symptoms, and, second, those resulting from increase in the size of the tumor, headache and visual disturbance. A surgical attack on a pituitary lesion is never indicated until vision is threatened. Roentgen therapy may diminish the size of a pituitary adenoma. The verified adenomas in the series under discussion here have been reviewed to determine whether surgery or roentgen treatment has produced the better end results and furthermore whether, in the presence of loss of visual acuity, reduction in the size of the visual fields and optic atrophy, roentgen therapy is to be preferred to surgery as the first method for relief of symptoms.

When a surgical procedure is suggested in the treatment of a disease, the first consideration is the mortality. In this series forty-four transphenoidal operations have been performed in thirty-seven cases with five deaths, an operative mortality of 11.3 per cent and a case mortality of 13.5 per cent, and 126 transfrontal operations in 106 cases with twelve deaths, an operative mortality of 9.5 per cent and a case mortality of 11.3 per cent. The total series of 143 verified pituitary adenomas has therefore a 10 per cent operative and 11.9 per cent case mortality. Of the 126 remaining cases, eighty-four have been adequately followed for two years or longer. These eighty-four cases have been divided into two groups, those in which operation was not preceded or followed by roentgen therapy and those in which such treatment was administered either before or after operation.

In reviewing the literature on the results of the treatment of pituitary adenomas, the necessity for establishing an accurate method for determining increase or decrease of visual function became at once apparent. In an attempt to rule out vague terms and generalities

I decided to adapt the method devised by Snell¹² for determining visual function, which has been accepted as the basis for determining compensation following ocular injuries by many state compensation boards. Briefly this consists in finding the coefficient of function for the visual field and visual acuity in a given case from standard tables. The product of these figures equals the percentage of visual efficiency. In this way a more accurate standard for comparison of gain or loss

TABLE 1.—*Operative Results in 143 Cases*

Mortality	Operative 10%	Case.....11.9%

in vision over a period of years can be obtained between the results of operation, as against operation plus roentgen treatment or roentgen treatment alone in this series of eighty-four adenomas.

Among these eighty-four patients thirty-eight were subjected to one or more operations and forty-six received roentgen treatment in addition to a surgical procedure.

In the group of thirty-eight on whom operation alone was performed, seven were operated on by the transphenoidal route, four acidophil and three chromophobe tumors, and thirty-one by the transfrontal approach, twenty-seven chromophobe and four mixed adenomas. In twenty-one of these cases the results were considered to be good. Beginning with an average visual efficiency of 35 per cent following operation, this was increased to 66 per cent over a period averaging 7.2 years. Two of this group have been followed for only three years and three for more than ten years. In seventeen cases a poor result followed surgical intervention. Beginning with an average visual efficiency of 32 per cent by the end of an average 7.2 years after operation, the average efficiency was 23 per cent. Five of these patients had a transphenoidal procedure, three acidophil and two chromophobe adenomas. The twelve transfrontal operations verified nine chromophobe and three mixed adenomas.

Postoperative visual efficiency.....		25%
38 cases. Average follow-up.....		7.2 years

Forty-six patients were operated on and also received roentgen therapy. Thirty-two fall into a satisfactory result group, having been followed for an average of seven years after treatment and showing an average increase in visual efficiency from 24.7 per cent to 60.5 per cent. Of these adenomas, fourteen were cystic and eighteen were solid. A transphenoidal operation was carried out in six instances on five acidophil and a single chromophobe adenoma. The transfrontal attack in twenty-six cases verified twenty chromophobe and six mixed adenomas. In fourteen cases the results fol-

lowing operation plus roentgen therapy were unsatisfactory. These cases were followed for an average of nine years and the visual efficiency fell from an average of 50.4 per cent after treatment to 36.5 per cent. Eight adenomas were cystic, six solid. In eight instances the transfrontal approach was carried through, verifying a chromophobe adenoma. In six cases a transphenoidal attack was used, revealing an acidophil tumor in four and a chromophobe in two instances.

Through the courtesy of the Roentgen Ray Department at the Hospital of the University of Pennsylvania, I have had access to the records of ten patients treated by roentgen rays alone and followed for an average of 3.7 years. While no tumor from any of these patients has been verified histologically the sella turcica was enlarged in eight instances, five clinical acidophil and three chromophobe tumors, with temporal field cuts on one or both sides and optic atrophy. Two patients had indications suggesting a basophilic adenoma. The average visual efficiency was 68.9 per cent and increased to 87.1 per cent after roentgen treatment.

The details of the roentgen treatment which these patients received are as follows: Five fields are used, two temporal, two occipital and one bregmatic. Each field is 12 cm. in diameter. At a distance of 50 cm. with a voltage of 200 kilovolts, a milliamperage of 20, an

TABLE 3.—*Results of Surgical Operation Plus Roentgen Therapy*

46 cases. Average follow-up.....	9 years

effective wavelength of 0.17 angstrom, a roentgen output of 43 per minute and two filters used, one of copper 0.5 mm. and one of aluminum 1 mm. in thickness, 1,600 roentgens is given over each field at a rate of 300 roentgens a day. Thus in three or four weeks a dose of about 3,200 roentgens reaches the tumor. If necessary this dose is repeated at the end of three months.

A review of the literature seems to indicate that about 25 per cent of pituitary adenomas are cystic, the remainder being solid. Of these 143 cases, sixty-two, or 43 per cent, were cystic. The criterion on which I have based the consistency of the tumor has been the operative notes. If the operator stated that at the time the capsule of the tumor was incised the contents flowed out with prompt or slow collapse of the mass, I have considered the adenoma to be cystic. If, however, after slitting the capsule the wound simply gaped open without spontaneous escape of the enclosed tissue and without reduction in its size, such an adenoma has been classed as solid.

My impression has always been that cystic tumors, because of their prompt collapse following incision of the capsule, gave the best and most immediate results in recovery of vision and enlargement of the fields. In a review of the twenty-one cases classed as "good results following surgery," this impression is sustained, for six of these tumors were solid and fifteen cystic. Furthermore, in the group of seventeen patients designated as having had fair results following surgery in twelve the tumor was solid and in five cystic.

12. Snell, A. C.: An Analysis of the Compensation Problem as It Relates to Ocular Injury, Arch. Ophthol. 53: 37 (Jan.) 1924.

Henderson,¹³ Schnitker,¹⁴ Dyke and Hare¹⁵ and Rand and Taylor¹⁶ have all stated that cystic adenomas are more roentgen resistant than solid. Of the thirty-two adenomas listed as showing good results following operation and roentgen treatment, fourteen were cystic and eighteen solid. In the group of fourteen adenomas classed as unsatisfactory following operation plus roentgen therapy eight were cystic and six solid. However, in results of the combined treatment the value

TABLE 4.—Results of Roentgen Treatment Alone

10 Cases	
Pretreated visual efficiency.....	68.9%
Posttreated visual efficiency.....	87.1%
Average follow-up	3.7 years

of roentgen therapy is hard to differentiate from that of the operation because of its administration before the patient's discharge from the hospital. Prior to three years ago I expected major results in visual improvement from operation and advised irradiation simply with the hope of prolonging this improvement.

A comparison of the thirty-eight cases treated by surgery alone with the forty-six in which the combined therapy was employed shows definitely that roentgen treatment is valuable. Twenty-one of thirty-eight cases, or 55 per cent, showed marked improvement following surgery alone. But the combined treatment produced marked improvement in thirty-two of forty-six, or 70 per cent. Again the increase in visual acuity averaged from 35 to 66 per cent following surgery and from 24 to 60 per cent when roentgen therapy was added.

Based on a review of the cases, I believe that, although it is impossible to determine prior to operation whether a pituitary adenoma is solid or cystic, roentgen exposure is indicated as a primary therapeutic measure. Only occasionally does it produce untoward results. In my experience three patients have become unconscious following irradiation, two dying in coma. In one case at least the fatality was due to hemorrhage into the tumor. All three patients were old "burned out" pituitary sufferers with advanced evidence of glandular hypofunction. Headache, nausea and epilation are unimportant consequences of this treatment.

In my opinion roentgen treatment does not render subsequent surgical intervention more difficult by causing adhesions or in other ways. I cannot supply figures showing its effect on operative mortality. I do, however, feel very strongly that roentgen treatment often lulls the patient into an unjustified feeling of security. Of eleven patients who had transfrontal craniotomies, roentgen treatment had checked or even slightly improved the visual efficiency. Operative treatment had therefore been postponed for from seven to twenty-eight months. When further loss of vision occurred and operative intervention was necessary, in eight the adenoma had broken through its capsule and overflowed the sella into the cranial cavity. Five operative deaths occurred in this group alone. Therefore, unless roentgen therapy produces within six weeks of the beginning of treatment a marked improvement in the visual fields

and visual acuity, surgery is indicated. That irradiation simply prevents further loss of vision and holds it stationary for a time is not enough. When again visual deterioration occurs, the surgeon may be confronted by a large spreading tumor—a hopeless situation from the surgical point of view with a high mortality rate. The patient has been allowed to drift past the optimal time for surgical intervention because of an apparent check in the progression of symptoms by roentgen therapy. Therefore I feel that whether irradiation is used preoperatively, postoperatively as a prophylactic measure or after the operative improvement has commenced to recede in an attempt to cause further shrinkage in the size of the adenoma, its use should be continued only if actual improvement can be shown by repeated and careful visual tests.

Of fifteen cases in which the records are available, marked evidence of improvement in vision and the perimetric tests was apparent after three weeks in nine. Four of these patients had acidophilic and five chromophobe adenomas. Among the other six cases, three could not be followed and three came to operation on an average of twelve months after the last roentgen treatment. Two patients had large spreading tumors that had escaped from the sella. One died following surgical intervention; the second was unimproved. The third patient had a cystic adenoma which was easily collapsed. However, visual efficiency had been reduced to 21 per cent and increased to 28 per cent following operation. The delayed improvement consequent on roentgen therapy described by Towne¹⁷ and appearing only after six months or a year has not been seen in this series. If roentgen therapy is effective, improvement should appear within six weeks of the commencement of a vigorous course of such treatment.

Complete surgical removal of an adenoma is usually impossible. The vessels forming the circle of Willis surround the sella, are often adherent to the capsule of the adenoma and may be torn if too radical an attempt at removal is attempted. The hypothalamic region above and behind the tumor may be injured during manipulation or retraction with consequent and often fatal hyperthermia. The safest surgical attack on an adenoma is an intracapsular enucleation with sufficient reduction in the size of the tumor to relieve pressure on the optic nerves and removal of all easily accessible capsule. Roentgen therapy should then be relied on

TABLE 5.—Surgery vs. Surgery Plus Roentgen Therapy

Surgery alone	38 cases
Marked improvement	21 cases or 55 %
Increase in visual efficiency.....	35% to 66%
Surgery plus roentgen therapy.....	46 cases
Marked improvement	32 cases or 70%
Increase in visual efficiency.....	24% to 60%

to prevent recurrence. My experience suggests that this treatment should be given within six weeks of the original operation. Every such patient should have visual field studies carried out repeatedly at three month intervals thereafter. In this way evidence of recurrence is promptly recognized and can be properly dealt with before the adenoma becomes too large.

The effect of roentgen treatment is beneficial in a sufficiently high percentage of pituitary adenomas to warrant its use preoperatively. In visual field studies an accurate and easily verified control of the results of

roentgen therapy is available. Three weeks' treatment as outlined should be administered with a careful perimetric field examination at the end of that period. Only if the visual acuity and fields are unimproved at the end of that period is surgical intervention justified. Postoperatively roentgen treatment seems definitely to prolong the period before evidence of recurrence of the adenoma appears.

3400 Spruce Street.

THE ROENTGEN THERAPY OF
PITUITARY ADENOMAS

MERRILL C. SOSMAN, M.D.

BOSTON

As physicians specializing in nervous and mental diseases, we have all known of the increasingly good results following surgical attack on the pituitary adenomas, results which have been steadily improving for the past twenty-five years. We have heard again this afternoon ¹ of the magnificent work which is being done by the neurosurgeon. I have no quarrel with surgeons but only admiration for their courage as well as their technical skill and for their low mortality, which, in the last ten years of Dr. Cushing's series,² reached the astonishing figure of only 2.4 per cent. (The mortality is not as low in the majority of neurosurgical clinics, being probably nearer 10 per cent.) Recently an accurate, complete and detailed report of a follow-up study of Cushing's 338 cases of pituitary adenoma by Henderson ³ stated that the good results following surgical

Chromophobe Adenomas: The Percentage of Patients Without Recurrence at Five Years, According to the Type of Operation and X-Ray Treatment ⁴

Treatment	No. of Cases	Cases Without Recurrence at 5 Yr.	
		No.	Percentage
Transphenoidal operation only.....	67	22	32.8
Transfrontal operation only.....	40	23	57.5
Transphenoidal operation plus roentgen therapy.....	49	32	65.3
Transfrontal operation plus roentgen therapy.....	31	27	87.1

procedure can be prolonged and some of the recurrences prevented by postoperative roentgen therapy.

If surgical therapy produces good immediate results and surgical therapy plus irradiation extends and prolongs those results, what can be expected from irradiation alone without surgical treatment? There are three important fundamental principles to be established before consideration of the results of roentgen therapy alone:

1. A survival period of three, five or even ten years is no criterion of results as it is in outspoken malignant conditions such as osteogenic sarcomas or uterine carcinomas. We must judge our results by the patient's restoration to health, a return to a normal mode of

living and, particularly in the chromophobe type of adenoma, by restoration of vision. On the whole, the degree of improvement in vision and the duration of that improvement are the best guides as to effective therapy. It is worthy of note here that failing vision was the chief complaint of 87.5 per cent of Cushing's 260 patients with verified chromophobe adenomas.

2. Nearly all the patients irradiated in Cushing's series, as reported by Henderson, were treated with relatively low voltage and small doses, and yet some extremely good results were recorded. One would now consider those patients as being definitely undertreated. With the modern accurate penetrating radiation one can and does give larger and more accurately measured total doses, spreading treatment over a longer period and using more portals.⁵ One can justifiably expect from present indications a greater effect on the tumor.

3. Pituitary adenomas are extremely variable in their rate of growth, their direction of growth, or extension, and their effect on health and vision. Like all adenomas of endocrine glands, they are even liable to spontaneous remissions, and one must keep this possibility in mind when evaluating results. It might be more valuable to analyze and compare failures rather than to consider only good results.

As sample cases, illustrating the wide variation in the symptoms, signs and results of treatment, I present in brief the histories of three patients:

REPORT OF CASES

CASE 1.—A man aged 47 years had had headaches for eight years, ease of fatigue for five years, failing vision for two years and a recent gain in weight. The visual fields showed large central scotomas and inferior quadrantal defects (Henderson's group 4). Visual acuity was 20/30 —2 in the right eye and 20/200 in the left. The basal metabolic rate was —37 per cent. Roentgenograms revealed an enlarged pituitary fossa 25 by 14 mm. in size, with partial destruction of the posterior clinoids and dorsum sellae but no general signs of increased intracranial pressure. Roentgen therapy was begun Aug. 3, 1935, three portals being used in rotation (both temporal areas and one midline supra-orbital area), with daily doses of 300 roentgens to one portal. The total number of treatments was nine (three to each portal), and the total dose was three times 900 roentgens in ten days. Objective improvement in the visual fields and in visual acuity was demonstrable by August 12, the day of the ninth treatment, and improvement continued after the cessation of treatment. The visual fields and the visual acuity had returned to normal at examination in February 1936, and they have remained normal to date (May 1939), almost four years. This response was unusually prompt but highly satisfactory, particularly in this patient, who is the brother of one of our house physicians. Physicians all know how members of their families are prone to develop complications and unusual reactions in response to standard therapy.

CASE 2.—This patient is quite a contrast to the first. Both his history and results of his physical examination were atypical, with the roentgenographic appearance of his sella contributing largely to the diagnosis. He was a retired bank teller aged 54, who for nine years had suffered petit mal convulsions and for three years grand mal attacks with failing memory, gain in weight, loss of libido and failing vision. Examination revealed slight right exophthalmos, bilateral primary optic atrophy with left upper homonymous quadrantanopia, partial anosmia, nerve deafness on the left and a basal metabolic rate of —23 per cent. These features were hardly suggestive of a pituitary adenoma, but the roentgenograms revealed marked destruction of the sella and of the adjacent sphenoid bone with an extension of the destructive process downward, backward and to the left,

where there was erosion of the tip of the petrous ridge. The observations could best be explained by a large pituitary adenoma, with invasion and destruction of the base of the skull and extension into the left temporal lobe causing the homonymous quadrantanopia and extension into the cerebellopontile angle causing the deafness on the left.

Röntgen therapy was instituted in January 1935, with rather mild doses of 300 roentgens a day to the temporal areas, treated alternately, until 600 roentgens had been given to each side. This dose was repeated in March, June and September of that year. There was definite improvement in that the grand mal attacks ceased, but the petit mal seizures continued although they decreased in frequency. With the idea that these seizures might be due to hypoglycemic reactions as reported by Wilder,⁶ the patient's blood sugar curve was investigated; it was found to be normal, and injections of insulin did not provoke an attack. The patient's visual fields, however, which are the best index of shrinkage of the tumor, improved only slightly during the irradiation and relapsed to their former state three months after the last treatment. For that reason surgical therapy was offered and accepted; on March 4, 1936, a large amount of tumor tissue was removed through a right transfrontal approach. The patient did not do well after his operation, and he succumbed two days later. At autopsy a huge tumor, 7 by 7 by 4 cm. in size, was found in the sellar region, surrounding the basal arteries and nerves, extending into both temporal fossae, more on the left, and projecting backward, compressing the pons and partly eroding the left petrous tip. Histologically it was a chromophobe adenoma of the pituitary gland. The sella was completely destroyed and the sphenoid sinuses were obliterated by the tumor. This patient may well be chosen to represent some of the failures in either irradiation or surgical treatment of pituitary adenomas. It was obviously impossible to remove more than an inconsequential portion of the tumor surgically and equally impossible to cause adequate shrinkage of the tumor by irradiation. The patient had allowed the tumor to progress to such a size that a satisfactory alleviation of symptoms was impossible by any means.

CASE 3.—This is more typical of what one can ordinarily expect, both clinically and as a result of roentgen therapy. This 30 year old Jewish WPA worker, who was first seen Feb. 14, 1934, complained of having had impotence for four years, blurred vision for three years, gain in weight and discomfort in cold weather for two years and frontal headaches for one year. Roentgenograms of his skull revealed an expanded sella measuring 24 by 30 mm. Physical examination showed adiposity of female distribution, a scanty beard requiring shaving but once a week, a pale dry skin, bitemporal hemianopia, and a basal metabolic rate of —30 per cent. Roentgen treatments totaling 600 roentgens to each temporal portal were given in February, April, September and November 1934. The first improvement in the visual fields was noted at seven months, no improvement having been apparent at five months. The right visual field was normal at eleven months, but there remains a permanent defect in the left lower temporal quadrant, similar to the defects often remaining after operation and interpreted by Henderson and Cushing as being due to counter pressure on the optic nerve by the margin of the optic foramen or the anterior cerebral artery.⁷ There has been no recurrence of visual failure to date (May 1939), over five years since irradiation has begun. Potency has returned intermittently and temporarily, but potency is not a reliable index of the efficacy of therapy, as it is affected by too many factors, local and constitutional as well as psychic. I mention it here only because it was the patient's chief complaint, of more importance to him apparently than his failing vision. The patient is otherwise in good condition, his headaches have disappeared and he has more vigor and endurance, but his basal metabolic rate remains low and he shaves but twice a week. No irradiation has been given since 1935.

My results with the chromophobe type of adenoma, with use of roentgen therapy only, are as follows: Fourteen patients were treated; two subsequently were

operated on (one as described in the report of case 2). The condition of four patients was hopeless from the start, owing to extensive invasion or intracranial extension (three were dead in three months). Ten cases were suitable for analysis or results, but in two of them therapy was too recent (under two years since first treatment) for evaluation at this time.

Seven of the remaining eight patients (87.5 per cent) have received marked benefits from their irradiations, both as to restoration of vision and as to return of the patient to normal living. Objectively demonstrable improvement in vision of one patient began by the ninth day of treatment (case 1) and of others at various periods up to seven months (case 3). Towne⁸ reported at the Eighty-Ninth Annual Session of the American Medical Association that objectively demonstrable improvement in the visual fields might be delayed for a year or even more after commencement of irradiation. The duration of improvement in my cases has lasted from three to five years, with no recurrences so far.

1. Failures, then, occur in the patients with advanced extensive lesions, either invasive in bone or with large intracranial extensions, the group who account for the bulk of Dr. Cushing's postoperative fatalities. (Two patients with borderline tumors which were incompletely removed surgically and then irradiated are still alive, working, and about 90 per cent efficient; they are not included in this group.) 2. Failures may also occur in the cases in which the tumor has been pressing on the optic nerves or chiasm so long that it has produced atrophy of the fibers. This is the same group for which Henderson reported failures after the surgical removal of the adenoma, even with postoperative irradiation. One of my cases fell into this group. Irradiation failed to relieve the defective vision, which the patient had noted for three years. An unusually satisfactory removal of the tumor two months later also failed to improve the visual fields. 3. Cystic tumors, which formed 17 per cent of Cushing's 260 chromophobe tumors, are said not to respond to irradiation. As far as I know, there were no examples in my small series. All but one of the tumors which failed to improve have been examined histologically either at subsequent operation or at autopsy. Henderson noted that even with cystic tumors the recurrences were avoided or delayed by postoperative irradiation, and he urged such treatment in all cases.

The dangers from or following irradiation must be considered. They are real but infrequent. Henderson noted that no late ill effects from roentgen therapy were found in Cushing's series. He did state that in one case extensive adhesions between the adenoma and the chiasm, which prevented a satisfactory surgical removal, were assumed to be due to extensive irradiation elsewhere for more than a year before operation. Henderson also reported that in no case was cystic tumor found after preoperative irradiation, but I have seen an acute hemorrhagic cyst develop after a fairly heavy single roentgen treatment for recurrence after operation. The patient went into coma in a few hours but was relieved by an immediate emergency operation. In Henderson's report, one case of bilateral cataract formation in a young person was attributed to heavy (and perhaps careless) preoperative irradiation. This is a definite possibility, as I have seen it occur under

treatment for other cranial conditions. Edema of the brain is often held up as a possibility, but in all the hundreds of patients I have irradiated for all sorts of cranial or intracranial conditions, I have yet to see a patient with postirradiation edema of the brain. Experiments lead one to believe that the nervous tissue of adults will stand a dosage up to 6,000 roentgens in any one area. One should keep below this dose, therefore, to avoid injury to the vessels and subsequent fibrosis, gliosis or necrosis. Henderson's opinion is that the real and greatest danger in irradiation without operation is the period of delay necessary to determine the results; i. e., while roentgen therapy is being tried, the failure promptly to remove the pressure on the optic chiasm may possibly result, with unsatisfactory responses, in a change from temporary relievable blindness to permanent optic atrophy due to degeneration of the nerve fibers. This question can be answered only by experience over many years and with a much larger series of cases than I am able to report at present. So far I have not seen any patient get worse during or immediately after irradiation, with the exception of the patient with cystic degeneration already mentioned.

A word about the acidophil tumors and acromegaly and their response to irradiation must be included for comparison. Almost everybody agrees that they respond more readily to irradiation than the chromophobe type, that the majority of them can best be treated by irradiation, particularly if there are no field defects (which are rare), and that they are much more liable to spontaneous remissions and waves of activity and inactivity. These tumors grow so slowly in the majority of cases that the eventual result is in doubt for many years. The most distressing symptom of nearly all the patients irradiated was headache, and this was definitely improved or entirely relieved in 90 per cent of the twenty-eight cases. Vaughan has reported our results in detail.⁹

We believe from the results in our cases that acromegaly (and gigantism in adolescents) can be stopped by reasonable doses of roentgen therapy; that the chief symptom, headache, can be relieved in 90 per cent of the cases, and that visual failure due to pressure of an expanding adenoma may also be relieved. Many of the patients with acidophil adenoma, however, go over into a stage of hypopituitarism spontaneously, and this cannot be prevented by roentgen therapy; in fact, it may be hastened by heavy irradiation. It is conceivable, however, that if beginning acromegaly is recognized early enough the hyperactive tumor can be stopped by irradiation, which allows the remaining normal portion of the gland to continue its normal function. Only time and many carefully studied and accurately followed patients can give the answer to that hypothesis.

721 Huntington Avenue. _____

ABSTRACT OF DISCUSSION

DR. GEORGE W. CHAMBERLIN, Philadelphia: Our ideas concerning the treatment of pituitary adenoma are changing. Until a few years ago, clinicians regarded these tumors as radio-resistant. This feeling arose in part from lack of suitable therapy equipment, which we now possess, and in part from our lack of experience in treating these tumors. Whatever the cause, there is now adequate evidence that roentgen therapy is valuable in the treatment of adenomas of the pituitary. According to statistics presented by Dr. Henderson in his review of

338 cases of pituitary adenoma from Dr. Harvey Cushing's series, about 30 per cent more patients remain well for five years if given roentgen therapy plus operation than remain well after operation alone. That is, 57.5 per cent of the patients who received transfrontal operation only were without recurrence for five years, whereas 87.1 per cent of those who received the same type of operation plus roentgen therapy remained free from recurrence for five years. Dr. Sosman has shown that those patients who have large tumors with extrasellar extensions give a poor prognosis by any method of treatment. Since these lesions are apt to surround fixed structures such as the carotid artery and thus make their surgical treatment hazardous or impossible, it seems reasonable to use roentgen therapy as the procedure of choice. For with the latter method, the result is dependent on cell sensitivity rather than on the size of tumor. I do not believe that preoperative irradiation, properly given, will produce changes in the tissue which make subsequent operation more difficult. The basis for this opinion is the experimental work of Dr. Pendergrass on the effect of radium on the normal tissues of the brain of dogs and also our clinical and pathologic experience in the treatment of brain tumors as reported by Dr. Alpers and Dr. Pancoast in 1933 and by Dr. Frazier, Dr. Alpers and myself in 1937. I believe that Dr. Grant will support this statement on the basis of his surgical observation of these tumors after irradiation. Another group of patients are those with very small tumors as evidenced by slight changes in the visual fields or a sella turcica of top normal size. Here again, in this relatively small group of cases, the technical difficulties encountered by the surgeon in finding the adenoma is sufficient reason for considering treatment by radiation therapy. It is my feeling that the larger group of patients comprising those who have a ballooned-out sella without extrasellar extension but with definite field defects and diminished visual acuity should also receive preoperative irradiation unless there is evidence of a rapid diminution in visual efficiency.

DR. ERNEST SACHS, St. Louis: I came here originally to agree with everything that Dr. Sosman had to say. I read his paper, which he was kind enough to send to me, but in the abstract in the program I read this sentence: "These results justify the conclusion that one should try irradiation in all cases of pituitary adenoma before resorting to surgical intervention," and that is the opinion that was also expressed by Dr. Grant. I must take exception to that opinion and for this reason: I think the clinician or the surgeon has to be guided by the amount of loss of vision that the patient has when he presents himself. A patient now in the hospital is unable with his right eye to read the biggest letters at a distance of 15 feet and in his left eye he has 15/200 vision. He is a farmer. He cannot see well enough even to plant corn in a straight line. To subject that man to a preliminary course of roentgen treatment I consider would be unwise in spite of the fact that there is an operative risk which we cannot deny. I believe that the most important thing to decide in each case is how much visual loss the patient has when he presents himself. If he has an adequate amount of vision and it seems comparatively safe to try high voltage therapy for a short period (I agree with Dr. Grant that it ought not to be tried for more than four or six weeks, anyway), I think it is all right to try roentgen treatment before operation; but if the vision is very seriously impaired I think it is a different story. Regarding the roentgen treatment after operation, I agree with Dr. Sosman that we should give high voltage therapy after the patient has been operated on with the idea of preventing a recurrence, but in my experience that does not always follow. I have in mind a patient who was operated on for the first time six years ago for a pituitary tumor with complete restoration of vision, and he did not receive high voltage roentgen therapy at that time. He was completely relieved for four years and then he returned with a recurrence, and he was then reoperated on and received roentgen therapy after the operation. He had his third recurrence this year and was reoperated on in spite of the fact that he had been given very considerable doses of x-rays by Dr. Moore of our x-ray department. How long he is going to be

⁹ Vaughan, Walter W.: The Place of Irradiation in Acromegaly, *Am. J. Roentgenol.* 40: 660 (Nov.) 1938.

free from his symptoms I do not know. On the other hand, if we see a patient who has a slight loss of vision, I certainly think we ought to give him roentgen treatment.

DR. MERRILL C. SOSMAN, Boston: I feel that I have gotten off lightly as regards the suggestion that I made in the abstract (which I made on purpose) that all patients be treated with roentgen rays first. If you will read the report that Dr. Henderson made, you will find that patients were classified according to the visual difficulty on admission, and that with certain types of visual difficulty, particularly when one eye is blind and the other has a hemianopia, the prospects of good recovery of vision are very poor. So that in the advanced cases that Dr. Sachs mentioned I think the prospects are bad by either or both methods of treatment in the majority of cases as shown in the analysis of a large number of similar groups of patients. In my experience it is not the degree of visual difficulty which is important but the duration over which that visual failure has lasted; and, if visual failure has been present over the period of a year, the chances again are poor either by surgery or by roentgen therapy. I still feel, because of the operative mortality, which averages about 10 per cent, that it is reasonable to try roentgen irradiation when the patient first presents himself and the diagnosis is made.

THE MANAGEMENT OF PATIENTS
WITH DIFFUSE PERITONITIS

CAUSED BY PERFORATION OF THE APPENDIX

THEW WRIGHT, M.D.

A. H. AARON, M.D.; J. S. REGAN, M.D.

AND

ELMER MILCH, M.D.

BUFFALO

In February 1935 we made a statistical and critical analysis of forty-four cases of diffuse peritonitis following perforation of the appendix treated at the Buffalo General Hospital and Buffalo Children's Hospital. In this series of cases there were twenty deaths, or a mortality rate of 45.4 per cent, in two institutions which represented a cross section of the average hospital in this country.

In addition, we obtained the following information: Ninety-seven per cent of the patients were operated on by six different surgeons, and no uniformity of treatment existed. We believe that, omitting surgical judgment, which is a personal and individual equation that cannot be evaluated, the chief means available to combat peritonitis is the intelligent use of morphine, fluids, duodenal decompression and transfusion. The various surgeons used one or two of these agents to the total exclusion of the remainder, and there was no unanimity of opinion as to the indications for their use.

For the sake of clarity we would emphasize the fact that this discussion is limited to diffuse peritonitis and does not include the other complications following perforation of the appendix.

To reduce this mortality rate of 45 per cent, it was obvious that we first had to know, if possible, why patients with diffuse peritonitis die. At postmortem examination these patients presented the following anatomic changes rather consistently: (1) tremendous distention of the entire gastrointestinal tract, (2) high

elevation of the diaphragm, (3) compression atelectasis of the lungs above the diaphragm, (4) terminal pneumonia, (5) marked stagnation of blood in the splanchnic and mesenteric vessels, (6) contraction of the spleen and (7) paleness and anemia of the liver.

We feel that these observations point to the fact that such patients die primarily for two reasons: shock and intestinal obstruction.

Keeping these anatomic manifestations in mind and realizing the alterations in physiology that they produce, one finds it possible to correlate them with the clinical picture.

The patient with diffuse peritonitis entering the fourth or fifth day of the illness has a cyanotic hue of the lips and finger nails, falling blood pressure and increased respiratory rate which are manifestations of the large amount of blood stagnated in the splanchnic and mesenteric vessels and not available for the peripheral circulation. The rise in the pulse rate is a compensatory effort of the heart to bring the blood, which it is receiving in a markedly diminished amount, to the tissues of the body.

The high elevation of the diaphragm and associated compression atelectasis are probably the chief factors in the production of the terminal pneumonia. As there is no evidence of primary disease of the kidneys at autopsy, the changes in the urine and blood are the result of dehydration.

With the background that we have constructed, let us now analyze each of the four therapeutic procedures mentioned, namely duodenal decompression, administration of fluids, adequate and intelligent use of morphine, and transfusion, and see what we accomplish in their use and attempt to arrive at concrete indications for employing them.

By means of continuous duodenal decompression as devised by Wangenstein¹ we attempt to alleviate distention by removing gas and fluid from the stomach and intestine and overcome to some extent the high elevation of the diaphragm, with the consequent compression atelectasis of the overlying lungs, and thus remove a

TABLE 1.—Diffuse Peritonitis, 1929-1934

Cases	Deaths	Mortality, Percentage
44	20	45.4
Average time, onset to hospitalization, 72 hours		

factor in the production of a terminal pneumonia. In addition, if we admit that an intestinal obstruction exists in every case, even though paralytic and not mechanical, we are to some extent combating the effects of a high intestinal obstruction.

In using duodenal decompression one must remember that the advance of the tube through the pylorus depends chiefly on the peristaltic action of the stomach. If, therefore, one delays introducing the tube until gastric peristalsis is lost because of the infection and subsequent distention, there can be little hope of the tube entering the duodenum and consequently there will be no real decompression of the small intestine. Another factor is that nausea and emesis vary with different individuals, and these symptoms should not be used as

From the Department of Surgery at the Buffalo General Hospital and the Children's Hospital.

Cooperation and aid were given by Drs. K. L. Terplan, Ernst Witebsky, R. S. Hubbard, N. C. Klendshoj and Erwin Neter.

an indication for beginning decompression. To illustrate: It has been our experience that one patient may complain of nausea and emesis with only 500 cc. in his stomach and that another may tolerate 2,000 cc. with no complaints, the latter statement having been proved at autopsy.

In discussing the parenteral administration of fluids one must consider the manifestations of dehydration and

Fig. 1.—Coronal section of a patient who died of diffuse peritonitis.

the associated altered urinary and chemical observations. This immediately brings up the subject of water balance, with its countless ramifications. All one can possibly

hope to do with fluids is to meet the increased metabolic needs and endeavor to keep the patient as nearly as possible in physiologic balance.

Prior to the renewed interest in the maintenance of water balance occasioned by Coller and Maddock,² we lost some patients because of dehydration. We have during the past few years been able to maintain patients even to the day of their death with a normal urine and a normal output and with normal blood values for urea, carbon dioxide combining power and chlorides. These are the only yardsticks at present with which one can measure dehydration, if indeed that is at all possible.

2. Coller, F. A.: Studies in Water Balance, Dehydration and the Administration of Parenteral Fluids, Minnesota Med. 19: 490-494 (July) 1936. Coller, F. A.; Dick, V. S., and Maddock, Walter S.: Maintenance of Normal Water Exchange with Intravenous Fluids, J. A. M. A. 107: 1522-1527 (Nov. 7) 1936. Coller, F. A.; Bartlett, R. M.; Bingham, D. L. C.; Maddock, W. S., and Pedersen, Svend.: The Replacement of Sodium Chloride in Surgical Patients, Ann. Surg. 105: 769 (Oct.) 1938.

Consequently, we administer just sufficient fluids to maintain the blood chemistry and urine within normal limits. As to the type of fluid, the blood chlorides are used as an index. Only a sufficient amount of saline solution is administered to maintain the blood chlorides at a normal level, with the remainder of the fluids given in the form of sterile distilled water. Early in our experience we produced edema by using more saline solution than was indicated physiologically. For the parenteral administration of fluids in the type of cases under consideration we employ the intravenous drip method exclusively.

The third adjunct is morphine. By the use of this drug one hopes to relieve pain, by far the most impor-

tant object, keep the patient quiet, diminish peristalsis and at the same time increase the tone of the intestinal musculature and combat distention. If the drug is administered properly after several large initial doses at comparatively short intervals, the patient may get along without any morphine for from six to eight hours. A sudden cumulative action of the drug must be feared

Fig. 2.—Splanchnic and mesenteric circulation of a patient who died of diffuse peritonitis.

and avoided by careful observation of the respiratory rate and general appearance of the patient.

Lastly, transfusion is a phase of this study which has proved most interesting and has led us to one or two observations which, as near as we are able to determine, have not been described before.

What are the indications for transfusion? The first is a slowly falling blood pressure associated with a gradually mounting pulse rate, regardless of the appearance of the patient. We have come to consider these

signs as a warning that the patient is entering a condition of shock with more and more blood stagnating in the splanchnic and mesenteric systems and less being fed to the heart for the peripheral circulation. Transfusion should be performed at this stage, if it is to do any good, before the blood pressure becomes imperceptible and the pulse uncountable and a true circulatory

Fig. 3.—Changes in the pulse rate and blood pressure which indicate transfusion.

collapse occurs. By transfusion we increase the volume of circulating blood, attempt to restore the blood pressure and supply blood to the peripheral tissues.

The second indication for transfusion is a marked fall in the total white blood cell count. The explanation for this phenomenon is that that particular hemopoietic system is being overcome by the infection and its products and is failing to respond. Transfusion should be done at this time without delay and without waiting for any further developments. Otherwise the white blood cell count will continue to fall and the condition become beyond redemption. The bone marrow itself is evidently not primarily damaged, as is evidenced by its response to transfusion, but its function is temporarily suppressed and transfusion is a factor in stimulating it to renewed activity.

There is a perplexing type of blood response in certain cases of diffuse peritonitis, namely persistent leukopenia, with the count ranging from 1,500 to 4,000 and the appearance of an increased number of young forms, or a degenerative shift to the left such as occurs in other acute unfavorable infections. Regardless of how much blood is given, the blood picture does not return to normal until the patient has overcome the infection. We have given as much as 5,200 cc. of blood in five days with no change in the white cell or differential count until the patient was on the road to recovery. We feel that this is a point in favor of the theory that the activity of the bone marrow is merely suppressed by the overwhelming infection and not primarily damaged.

We use from 750 to 1,000 cc. of blood for the average transfusion given indirectly. No ill effects from the administration of such large quantities of blood given at frequent intervals have been noticed. The hemoglobin content, red blood cell count, icteric index, van den Bergh reaction and urine remain normal.

To apply the aforementioned principles, a more or less definite regimen of treatment had to be worked out for

all patients with diffuse peritonitis. No one appreciates better than we the fact that medicine is much more than an exact science and that no definite rules for an entire group can be formulated because almost every case presents a problem peculiar to itself. It seemed, however, that a systematic plan embodying the foregoing principles might be formulated which would be applicable in most cases and still sufficiently flexible for individual variations. Consequently, during the past five years we have endeavored to fit every case as far as possible into the following plan:

No patient is sent to surgery until the shock, distention and dehydration are more or less successfully combated. We feel that by superimposing the shock of an operation, no matter how rapidly and gently it is performed, on patients already exhibiting to some degree the manifestations of shock, the mortality rate will be definitely increased. To correct these conditions will rarely defer operation more than two or three hours.

Every patient is returned from surgery with the following orders: A hypodermic of morphine sulfate 0.015 Gm. is administered for pain, restlessness and nausea. This is repeated as often as necessary, and the only contraindication is a respiratory rate of 12 or lower.

A continuous intravenous drip is instituted immediately, 10 per cent dextrose being alternated with 5 per cent dextrose in amounts to meet the individual requirements.

Duodenal decompression is inaugurated immediately.

The patient's blood is typed and cross agglutinated so that he may receive a transfusion without delay when the aforescribed indications arise.

A complete blood count and urinalysis are performed daily.

The blood pressure and pulse rate are taken every hour.

There are daily estimations of the urea content, carbon dioxide combining power and chloride content of the blood.

Fifty cc. of 50 per cent dextrose is administered twice daily in an attempt to get an additional 50 Gm. of dextrose into the body every

twenty-four hours as nutrition for the cardiac musculature.

The patient is placed in Fowler's position,³ and nothing is administered by mouth.

These orders adequately take care of the routine procedures, and as the need for individual treatments arise, such as the use of oxygen, they can be ordered.

All that remained now was the practical application of the principles just discussed in a series of cases comparable in every respect with those reported in 1935 to prove whether or not these factors would influence our mortality rate. In this paper we are reporting sixty cases of diffuse peritonitis treated as we have outlined.

Cultures of the peritoneal exudate were taken in all but two instances, or in 96.7 per cent of the cases. Positive results were obtained in all. The various organisms reported were *Bacillus coli*, *Streptococcus haemolyticus*, *Streptococcus faecalis*, *Bacillus aerogenes*, *Bacillus pro-*

Fig. 4.—Average length of life of patients who died after operation in the two series of cases.

3. Fowler, G. R.: Sitting Position in the Treatment of Appendical Peritonitis, *M. Rec.* 57: 617-623, 1900.

teus and *Staphylococcus aureus*. It is interesting to note the comparative absence of anaerobic organisms although definite attempts were made to demonstrate them in each instance. The pathologic reports confirmed the diagnosis of appendical involvement in all cases. The patients were ill at home before hospitalization an average of 72.4 hours. The physical examination in every instance confirmed the diagnosis of diffuse peritonitis. All were operated on by one of three surgeons, each familiar with the various standards and criteria set forth. The operative procedure was appendectomy and drainage in each instance. The average hospital stay of the patients who survived was 27.27 days.

We have outlined the requirements each case had to fulfil before inclusion in this series to show that in each and every instance we were dealing with a patient with diffuse peritonitis due to perforation of the appendix.

In this series of sixty cases we had seven deaths, representing a mortality rate of 11.7 per cent. One of these deaths, after an apparent recovery, was due to a volvulus necessitating a resection of 3 feet of small intestine. One patient bled to death from an erosion

TABLE 4.—Diffuse Peritonitis, 1935-1939

through a blood vessel in the cecum although his peritoneal cavity at the time of autopsy showed no evidence of peritonitis. The remaining five patients suffered no complications and died of peritonitis. All the patients were examined post mortem. *Bacillus coli* was reported five times, *Streptococcus haemolyticus* once and *Staphylococcus aureus* once. Blood cultures were negative.

It is interesting to note that in the cases reported in 1935 the patients who died lived an average of only 4.2 days subsequent to operation. In this series the seven patients who died, treated as outlined, lived an average of 13.8 days subsequent to operative intervention.

A compilation of the mortality rate in the United States for diffuse peritonitis following perforation of the appendix made by Bower⁴ revealed an average mortality rate of 33 per cent. Lied's clinic⁵ in Norway published a mortality rate of 27.39 per cent. We believe that the procedures described, used for the indications we have mentioned, have reduced the mortality rate from diffuse peritonitis following perforation of the appendix in the Buffalo General Hospital and Buffalo Children's Hospital from 45.4 to 11.7 per cent.

Density of World Population.—The average density of world population as a whole is nearly 41 persons per square mile, as we have seen. Yet the populations on over 81 per cent of the total land area are living at densities under 40. About 14 per cent of the population of the world—roughly one person in seven—is living at densities of 600 or above, that is with one acre or less per person, on an even personal distribution of area. —Pearl, Raymond: The Natural History of Population, New York, Oxford University Press, 1939.

APPENDICITIS: NEWER METHODS OF TREATMENT

J. SHELTON HORSLEY, M.D.

JOHN S. HORSLEY JR., M.D.

AND

GUY W. HORSLEY, M.D.

RICHMOND, VA.

The 16,000 deaths every year in the United States from appendicitis are quite unnecessary. Early diagnosis and prompt treatment for appendicitis, as for diphtheria, should make the mortality from either of these diseases almost negligible. In late cases, however, the analogy limps, because late in diphtheria treatment is of practically no avail, whereas in the late stages of appendicitis proper treatment is usually successful.

In the early stages of appendicitis almost any kind of appendectomy will do, but in the late stages skillful technic and physiologic procedures frequently make the difference between life and death. Late and neglected cases result largely from lack of appreciation of the importance of early operation, but, though education may do much to lower the incidence of late cases, there will doubtless for various reasons always be a considerable number of them. A large percentage of patients with a ruptured or gangrenous appendix operated on at St. Elizabeth's Hospital have had a purgative for indigestion or abdominal pain. "Late" does not necessarily mean in point of time but connotes the progress of the pathologic lesion. An "early" appendicitis may with a purgative or an enema become "late" and gangrenous in twenty-four hours. The prevalence of the conservative or Ochsner treatment for acute appendicitis and the so-called freezing of the appendix by icebags to the abdomen are also responsible in many cases of appendicitis for the development of abscess or peritonitis.

TREATMENT

Since Jan. 1, 1931, we have adopted five points for the routine treatment of all patients with acute appendicitis:

1. Immediate operation is done as soon as the diagnosis is made, no matter what the stage of the disease.
2. A McBurney or gridiron incision is made, and the appendix is always removed. We have not left an appendix in during this period.
3. The tissues are handled gently, suction is used instead of sponges, and no gauze sheets or packs are placed within the peritoneal cavity.
4. The stump of the appendix is treated simply, being merely ligated, severed and disinfected.
5. Physiologic rest of the gastrointestinal tract is effected by limiting the oral intake and avoiding proctoclysis. In all cases of spreading peritonitis or when a perforation or abscess exists, essential water and electrolytes with some calories are given intravenously by 5 per cent dextrose in saline or Ringer's solution. If there is distention, the stomach is decompressed by inserting a nasal tube to the stomach or duodenum and, if the distention is great, continuous suction is applied.

While patients do not usually die within the first eight or nine hours from a gastrointestinal perforation, which a ruptured appendix is, they may acquire a fatal infection during this time unless there is prompt and

From the Surgical Department of St. Elizabeth's Hospital, Read before the "and Proctology at the Ninetieth Annual Ses Association, St. Louis, May 18, 1939.

proper treatment. This is shown by the history of perforating peptic ulcers. It seems a good surgical rule to close a gastrointestinal perforation as soon as possible. No one denies the wisdom of removing an acutely inflamed appendix before it has ruptured.

If the appendix has ruptured and there is a local abscess, the abscess is opened as gently as possible without disturbing the adhesions except just enough to gain access to the appendix. A suction apparatus withdraws the pus. In peritonitis this is also done, but under no condition is gauze packing placed or sponging with gauze used to remove pus. A gauze sponge that removes some of the pus also forces into the tissues sepsis which otherwise might not be absorbed. It may not appear elegant to see pus running over the wound and the intestine, but it is much better than to press even a small portion of it into the tissues. If a suction apparatus is not available, a catheter with a syringe attached can be used.

The treatment of the stump of the appendix is simple. The base is ligated with stout chromic catgut but is never clamped. Clamping the base and placing the ligature in the bite of the clamp crushes the base unnecessarily, whereas the only tissue to be injured should be that within the grasp of the ligature, which makes a much narrower trauma than a clamp. The appendix is clamped a short distance from the ligature, surrounded with moist gauze and severed with the electric cautery. The stump is disinfected with pure phenol, curetted and again disinfected with pure phenol. The ligature on the stump is threaded in a needle and passed through adjacent peritoneum-covered fat. This is done to promote the absorption of the stump and to protect it from the pressure of the drainage. No sutures are placed in the cecum and no effort is made to bury the stump of the appendix.

The mortality rate in this series would seem to demonstrate that the arbitrary adherence to any so-called law of surgery is not always wise. To be sure, in suturing large wounds in the intestine the peritoneal surfaces should be brought together, but in a small puncture the mucous membrane frequently heals satisfactorily if approximated. This is not to say that the principle of uniting peritoneum to peritoneum is wrong, but in science there is no creed and no inviolable law, and the fact that a large wound of the stomach or intestine should be sutured so as to approximate the peritoneal coats does not necessarily imply that a small wound under different conditions should be treated in the same way. Willis¹ has shown that the mortality rate of intestinal wounds made by small shot is lower when no surgical operation is done and the perforations are not sutured than when there is a formal operation and the intestinal wounds are sutured. This is because in these small wounds the mucous membrane protrudes and stops the gap, and healing is satisfactory.

Burying the stump of the appendix creates a cavity in which necrotic material, the stump of the appendix and a foreign body, the ligature, are enclosed, and the purse-string suture which buries the stump cuts off some of the blood supply. This would seem to be an ideal method for creating an abscess, and as a matter of fact it apparently does. Thus, H. E. Robertson,² pathologist at the Mayo Clinic, has found that in all necropsies in cases in which the appendix has been removed incidentally during some other operation there is a pocket

of pus in this cavity up to twenty-one days after the operation. Fortunately it usually ruptures into the intestine, but it may not always do so. Dr. Robertson says: "For a long time I have been, in season and out of season, inveighing against the custom of burying the stump of the amputated appendix. It strikes me as wholly illogical and, worse than that, a dangerous procedure. The well known ostrich with his head in the sand hasn't very much on this custom."

The McBurney incision gives ample access in most cases of appendicitis and can be enlarged if necessary. It is particularly adaptable in suppurative cases because in such instances the wound is not closed. One or two cigaret drains and a soft rubber tube are inserted, and the peritoneum is lightly sutured around the drains. The rest of the wound is left open and packed with petrolatum gauze. When such wounds are sutured, suppuration of the abdominal wound often follows and there are pockets of pus. This treatment has been advocated by H. A. Gamble of Mississippi in all cases of peritonitis. It is a valuable contribution.

The cigaret drains are left in for about two days, though if the temperature continues high and the pulse is rapid the drains are not disturbed until the temperature and pulse rate come down. Drainage is not solely mechanical, but the presence of the gauze cigaret tends to induce pouring out of lymph around it and washes out the sepsis. The petrolatum gauze is not removed for several days. The wounds usually heal satisfactorily and may be drawn together with adhesive tape.

So far as we know there have been in this series only six cases of postoperative hernia in 119 drainage cases, and they have all occurred in cases in which there was rather extensive, long draining sepsis.

The principles laid down by Hilton³ in his classic work on rest and pain about 1863 still hold. Physiologic rest is one of the best therapeutic agents, and in order to apply it the function of an organ or tissue must be determined and either abolished or diminished as much as possible. Fluids are absorbed chiefly from the right half of the colon, and when proctoclysis is given it not only throws more strain on the site of the appendectomy but, instead of giving rest, incites peristalsis and burdens the adjacent intestine with increased absorption of fluids. When there is perforation, an abscess or peritonitis, the patient is given intravenously 5 per cent dextrose in Ringer's solution continuously, usually from 150 to 250 cc. an hour. If the blood pressure is low, this amount is increased. If the patient is quite ill we use an intravenous cannula instead of a needle, and the phleboclysis may be continued for several days. Nothing is given by mouth except a small amount of water. If there is distention a Jutte or a Levine tube is passed through the nose; then the patient may have water more freely if the tube is kept open.⁴

Five per cent dextrose in salt solution, in Ringer's solution or in distilled water may be now obtained in large ampules and if properly given almost never causes a reaction. Our statistics at St. Elizabeth's Hospital show that the incidence of pulmonary embolus after the intravenous use of this fluid is less than the average in many other hospitals, being 3.57 per cent of all deaths in surgical cases. It should be given without the so-called drip apparatus, merely a graduated glass

container and a thumb-screw being used to regulate the flow. The drip device is not only unnecessary but is positively dangerous. Terplan,⁵ before the Buffalo Pathological Society, reported a case in which sudden death followed the intravenous drip of 5 per cent dextrose solution and necropsy showed air trapped in the main stem of the pulmonary artery. When the patient strains and the venous pressure is high the fluid is forced back; when the patient suddenly ceases to strain some of the air that has been compressed in the drip apparatus may be sucked in. It adds an utterly unnecessary complication to the administration of a very effective therapeutic agent, because the rate of flow can be regulated more accurately by the graduated container than by the drip.

The patient is propped up in bed and an adequate amount of morphine is administered at regular intervals. In many of the drainage cases hot dressings of super-saturated solution of boric acid are applied over the abdomen. Neither enemas nor purgatives in any form are used until the patient is out of danger.

In our series there have been four cases of fecal fistula; all of them have healed satisfactorily within three weeks from the time of their appearance, with no further operative treatment.

Unless all these five points are followed, it would doubtless be unwise to adopt some of them, such as the removal of the appendix in every case and immediate operation. Some of these five points, such as the McBurney incision, immediate operation and the simple treatment of the stump of the appendix, have been used by us for many years before 1931, but it is only since that time that they have been combined with two other extremely important points; that is, giving physiologic rest by supplying fluids intravenously, and the use of suction for removing pus instead of sponging or placing gauze packs in the abdomen.⁶

We seldom encounter paralytic ileus or mechanical obstruction. When distention does occur we use the nasal tube with suction, phlebotomy and an oxygen tent with high concentration of oxygen. The benefit of the

occur abundantly in the infection it might be well to use sulfanilamide. While we have given sulfanilamide to some of these patients, the difference between their convalescence and the convalescence of those who were not given sulfanilamide is not impressive. It must be borne in mind that large doses of sulfanilamide may not be innocuous.

When no drainage is used the patient is kept in bed about nine or ten days and a few days later is permitted to return home. The practice of getting a patient up the second day after operation and having him leave the hospital on the third day is more spectacular than scientific. It has been well demonstrated that wounds in the

* This patient also had a gangrenous intestine at the time of operation.

intestine are weaker the second or third day than in the first twenty-four hours and then they gradually become firm again. While of course the procedure of having the patient up two or three days after the operation is spectacular and in many instances can be done without injury, it seems highly probable that if the convalescent is kept at rest for a sufficient time for firm healing of the wound the subsequent complications and sequelae will be fewer. Ogilvie⁷ of London, a distinguished authority on surgery and a learned physiologist, said in a Mayo Foundation lecture in 1937:

As a physiologic mechanism the abdominal wall demands activity. As an injured structure it requires rest for repair and relief from strain for security. A well sutured wound has a tensile strength of about 40 per cent of that of the tissues before they were cut. During the first few days the tissues undergo autolysis, while the sutures are being digested. By the fourth day the strength of the wound has sunk to some 20 to 25 per cent of the original. From the fifth day onward fibroblasts are laid down rapidly and the strength increases, so that by the sixth day it is 50 per cent and by the tenth day about 90 per cent of the normal. . . . But to allow or force him [the patient] to walk before the tenth day is to permit physiologic idealism to override pathologic common sense.

Our report covers a period of eight years and four months, from Jan. 1, 1931, to May 1, 1939, and includes all the cases in which disease of the appendix was the sole or the chief reason for the operation. Cases in which the appendix was removed incidentally to another operation are not included in this list. There have been 972 cases with six deaths. Of these, only one patient, whose intestine was also gangrenous, died of peritonitis. A brief summary of these deaths follows:

REPORT OF CASES

CASE 1.—A white woman aged 34 had retroversion of the uterus and what appeared to be acute appendicitis. The appendix was removed, but an abscess was found in the left ovary and tube which involved the ileum so closely that it was necessary to resect some of the ileum. The abscess was in no way connected with the appendix, though the appendix showed acute inflammation. Intestinal obstruction and a localized left-sided peritonitis developed and the patient died five days later. The

use of sulfanilamide in appendicular abscess or in spreading peritonitis from appendicitis has not been definitely determined. Primary or hematogenous peritonitis is frequently from streptococci, and here sulfanilamide is extremely helpful. A patient treated by one of us (J. S. H. Jr.) who had a primary peritonitis and who was given sulfanilamide freely recovered with remarkable promptness. This was dramatic, but though the preoperative diagnosis was appendicitis the appendix was not diseased and the offending organism was the hemolytic streptococcus. In appendicular peritonitis the colon bacillus (*Escherichia coli*) usually dominates and sulfanilamide has little or no effect on it. If streptococci

6. Horsley, J. S.; Horsley, J. S., Jr., and Horsley, G. W.: Appendicitis: Its Diagnosis and Improved Methods of Treatment, Virginia M. Monthly 65: 207-213 (April) 1938.

prime cause of death was not appendicitis, but since the appendix showed acute inflammation it is included in this series.

CASE 2.—A white man aged 84 complained of pain in the right side of the abdomen which was not well localized but was more prominent over the upper and lower portions of the right side of the abdomen than elsewhere. Under local anesthesia his appendix was removed and the tip was found to be high up almost under the liver. It was very adherent. At the tip was a concretion, and the appendix around this showed some inflammation though no actual pus. It was thought that this high location of the appendix accounted for the pain in the region of the gallbladder. Fourteen days after the operation the patient died. Necropsy showed a partly gangrenous gallbladder filled with pus and containing a very large stone. This condition was obviously present at the time of the operation but the diagnosis was missed because of the location of the appendix and because under the circumstances it did not seem advisable to make an incision over the gallbladder, which had originally been contemplated.

This patient, too, died from something not connected with the appendix. It was a case of missed diagnosis. It might be permissible to omit this case from the statistics of deaths from appendicitis, but on the whole it is probably better to include both of these cases.

CASE 3.—A white man aged 59 had a gangrenous appendix removed with satisfactory recovery except for slight pleurisy on the tenth day. He was preparing to go home when he died suddenly from pulmonary embolism on the sixteenth day after operation.

CASE 4.—A white man aged 50 had acute appendicitis. He had taken laxatives and purgatives. He was obese and chronically addicted to alcohol. The appendix was not ruptured but was acutely diseased. He died of uremia on the sixth postoperative day. The necropsy showed no peritonitis. There was cirrhosis of the liver and acute nephritis.

CASE 5.—A white man aged 72 had acute appendicitis with a retrocecal appendicular abscess. There was little pain and it was thought that the lesion was a cancer. Operation showed an abscess. The appendix was removed and the abscess drained. There was an exacerbation of chronic bronchitis with pulmonary edema. This was apparently controlled, but it recurred in forty-eight hours and the patient died five days after the operation with paralytic ileus and pulmonary edema. There was no spreading peritonitis.

CASE 6.—A white girl aged 17 years was brought to the hospital in rather a desperate condition. She had been delivered of a normal pregnancy three weeks previously. She complained of pain in the right side which had been present four days. There was a large amount of pus in the urine and at first it was thought that she had pyelitis. At operation there was a ruptured appendix, spreading peritonitis and about 3 feet of gangrenous intestine. The appendix was removed and the gangrenous intestine was resected. The patient died eight days later with an overwhelming infection.

With the six deaths in 972 cases there is a mortality rate of 0.617 per cent. If the first two cases mentioned are excluded from the deaths from appendicitis, the mortality rate would be 0.41 per cent.

The following six cases are briefly reported as illustrations. All of the patients recovered satisfactorily.

CASE 7.—A baby girl aged 8 months had severe abdominal pain, with a temperature of 102.5 F., a pulse rate of 176 and a white blood cell count of 27,800, with 70 per cent neutrophils. A large gangrenous appendix in a mass containing an abscess was removed. The patient is in good condition now.

CASE 8.—A white girl aged 4 years had acute appendicitis of about thirty-six hours' duration. On admission to the hospital the temperature was 104 F., the pulse rate 130 and the white blood cell count 20,000 with neutrophils 89 per cent. At operation there was extensive spreading peritonitis, and the appendix, which pointed toward the umbilicus, had ruptured near its tip. There were very few confining adhesions and the contents of

the appendix emptied freely into the peritoneal cavity. The appendix was removed and the usual treatment was given. No sulfanilamide was administered. The patient was rather ill for several days. Her highest temperature the day after operation was 104 F. and the pulse rate 138. Three days after operation the temperature was 100 F. and the pulse 110. From that time on she made a satisfactory recovery. There was no hernia and the patient is now in excellent condition.

CASE 9.—A white boy aged 4 years had a rigid and distended abdomen and a large mass in the lower portion of the abdomen. The white blood cell count was 35,000, temperature 103.8 F., pulse 144. There was a ruptured appendix, a large abscess containing about 250 cc. of pus and extensive spreading peritonitis. The appendix was removed and the peritoneal cavity drained. The temperature the following day was 103.2 F. and the pulse from 140 to 150, but these became about normal after five days. There was a flare-up of temperature on the tenth day, but it returned to normal on the fourteenth postoperative day. The patient had some fecal drainage for about eleven days following operation, but the fistula healed and he was discharged from the hospital on the twenty-third postoperative day. He has remained well.

CASE 10.—A white man aged 33 had a temperature of 99.2 F., a pulse rate of 88 and a white blood cell count of 12,800, with neutrophils 87 per cent. There was a mass in the lower right quadrant of the abdomen. Nine months before admission to St. Elizabeth's Hospital an appendicular abscess had been opened and drained elsewhere but the appendix was not removed. The appendix was removed from very dense adhesions. The wound was drained. There was a fecal fistula for a while, which closed spontaneously. The patient left the hospital thirty-three days after the operation and when heard from recently he was in excellent condition.

CASE 11.—A white man aged 27 had a large mass in the lower right side of the abdomen; the temperature was 99.4 F., pulse 96 and white blood cell count 20,000. A gangrenous and ruptured appendix was removed from an abscess. Convalescence was uneventful except for drainage of some fecal material which began on the eighth postoperative day and closed before the patient was discharged from the hospital on the twenty-eighth day after admission.

CASE 12.—A white man aged 20 on admission had a temperature of 102.2 F., pulse 120, respiratory rate 24 and white blood cell count 14,800, with neutrophils 89 per cent. Two months previously he had been treated conservatively by his physician and dismissed. Then he entered another hospital and a diagnosis of acute appendicitis with abscess was made and the patient was treated by the Ochsner method. Later the abscess was drained through the rectum. He was dismissed from the hospital and went home but continued to have a fever. Twelve hours before admission to St. Elizabeth's Hospital he had a severe attack of acute appendicitis. At operation there were very dense adhesions, a large amount of foul pus and spreading peritonitis with rupture of a pelvic abscess which contained the appendix. The appendix, gangrenous and ruptured, was removed. The patient nine months after the operation is in excellent condition and free from symptoms, and there is no postoperative hernia.

SUMMARY

In the period from Jan. 1, 1931, to May 1, 1939, 972 patients have been operated on by the surgical staff of St. Elizabeth's Hospital for appendicitis. Every patient with acute appendicitis or peritonitis from appendicitis was operated on as soon as the diagnosis was made, and in every case the appendix was removed at the time of operation. The advantages of this over the expectant or conservative treatment or over treatment in which the abscess is opened and the patient returns home to have the appendix removed later are obvious. Not only the mortality and the morbidity rate but the financial burdens on the patient are lessened. However, immediate operation and removal of the appendix must depend on the other points, on the use of suction, giving the intestine a rest by intravenous injection instead of

proctoclysis, handling the tissues gently and simple treatment of the stump of the appendix. The examples that have been given show some of the desperate cases that we have had. Not one of the deaths was due to peritonitis except in one case in which it was necessary at the time of operation to resect gangrenous intestine.

It would seem that the general biologic principles that have been followed here should greatly reduce the morbidity and the mortality in the late cases of acute appendicitis.

617 West Grace Street.

ABSTRACT OF DISCUSSION

ON PAPERS OF DRS. J. S., J. S. JR. AND G. W. HORSLEY
AND DRS. WRIGHT, AARON, REGAN AND MILCH

DR. FREDERICK A. COLLIER, Ann Arbor, Mich.: The mortality rate of acute appendicitis is much higher than it should be and there has been little if any improvement in the results of treatment of the disease in the last twenty-five years. The proper treatment for the disease is removal of the appendix while the infection is still limited to the appendix. Patients die from complications and not from acute appendicitis. If the diagnosis were made early and the appendix removed, the mortality would be negligible. I believe that obstruction of the appendix plays an important role in initiating the sequence of events as they occur in acute appendicitis. Studies in our clinic showed definite evidence of obstruction in 93 per cent of appendixes the site of acute infection. The diagnosis of appendical obstruction, the initial stage of acute appendicitis, can be made without leukocytosis and fever, and treatment carried out then will prevent complication. Another cause of delay in making the diagnosis of acute appendicitis is a not uncommon belief in the existence of vague entities such as "abdominal flu," food poisoning and food idiosyncrasies. Let us not wait for peritonitis with its fever and high leukocytosis before we make the diagnosis. The use of cathartics and purges for abdominal pain probably is the greatest single cause for peritonitis. There is the greatest difference of opinion as to the correct way to handle peritonitis. Shall we remove the appendix immediately or shall we defer operation while the patient is brought back to normal chemical balance? My experience is in accord with that of Drs. Wright, Aaron, Regan and Milch. I found that the mortality was entirely in the patient with diffuse peritonitis secondary to appendicitis. We removed the appendix in these patients in a routine way shortly after admission to the hospital with a mortality in that group of over 40 per cent. Ten years ago we began to follow the policy of deferring operation until the dehydration, hypochloration and ketosis were corrected, with a resulting diminution in the mortality of that group to about 8 per cent. I am unable to see anything new in the Horsleys' approach to the treatment, as what they advise is still the common form of treatment in this country. They are so skilful that their results are better than those usually obtained by others following the same method. I disagree with their advice always to remove the appendix immediately on seeing the patient. A patient with widespread peritonitis who has been vomiting and sick for from three to five days is the worst possible subject for an anesthetic and an operation.

DR. SIDNEY A. PORTIS, Chicago: The high mortality associated with acute appendicitis should not necessarily be laid at the door of the surgeon but should be brought home to the general practitioner or internist who first sees these patients and procrastinates before operative intervention is done. Fever has been regarded as a critical feature of this disease, and frequently one resorts to the use of mouth temperatures, which may be relatively normal, when elevations may be more accurately determined by the routine taking of rectal temperatures. I wish to add a note of warning against the indiscriminate use of fluids in cases of peritonitis. These fluids should not be given too rapidly. Pouring fluid into the veins may produce a right ventricular heart failure, with resulting passive hyperemia of the liver. This may affect liver function, and since one tries to preserve liver function in the treatment of infections, one may be defeating one's purpose by overzealousness in giving too

much fluid. Too much chloride should not be given to patients because it may produce a tissue edema. The amount of chloride intake should be very carefully evaluated for each case.

DR. NIELS C. KLENSHOJ, Buffalo: It has been my privilege to observe the work on diffuse peritonitis following appendicitis with perforation which Dr. Wright and his associates have presented. Irrespective of the controversial issues from the surgical standpoint, the main value of this work lies in the study and understanding of the altered physiology in these cases and the use of available means to combat such changes. Dr. Wright and his associates did not bring up very many of the laboratory data which they have on these patients, and I should like to add a point or two. These patients, when brought to the hospital, usually present a markedly lowered carbon dioxide combining power. This is not a primary condition but rather secondary, a result of severe dehydration and failure of the kidneys to eliminate and help maintain normal acid-base balance of the body. One of the complicating factors is that these patients, when brought to the hospital, have been sick for quite some time and may have had repeated emesis. This condition tends to produce alkalosis, and it is quite possible that this may alter the reported carbon dioxide figure toward a more normal value and thus give the surgeon a false sense of security. The actual loss of total base in these cases may quite well exceed what one might superficially estimate on the basis of the carbon dioxide figure.

DR. SARA M. JORDAN, Boston: I should like to congratulate the Program Committee on this symposium on appendicitis, which obviously needs to be presented often at these meetings, and I am glad the gastro-enterologists have it today. The papers which were given here today show the statistics on peritonitis. The excellent presentation by the Horsleys and by Dr. Wright and his associates show us what we have to face if we neglect the diagnosis. I should like to rise in defense of the surgeon as Dr. Portis did, to say that there probably is no problem in medicine which requires greater discretion than in the matter of the decision when to operate for appendicitis and when to consider the condition on a neurogenic basis. The problem of avoiding unnecessary appendectomies is not always simple and where there is doubt as to the presence of organic disease in the appendix it is, of course, much the lesser of two evils to operate and treat postoperatively for a functional condition than to delay surgery until complications have occurred.

DR. M. PINSON NEAL, Columbia, Mo.: Are we discussing appendicitis or its complications? It makes a great difference whether one is content to ride along with the "horse and buggy" diagnosis and include the complications with the disease, or whether one separates true appendicitis from the complications that arise through neglect, delay or improper treatment, often self administered. Any one who makes a diagnosis of appendicitis and not of its complications and then sits on the sidelines and watches is making a costly mistake. The authors opened but did not emphasize a most important yet an old story, the unwarranted condemnation of the blood count. A common error is to depend on the total leukocyte count, which is often noninformative or misleading. Frequently patients are kept under observation because a total leukocyte count was recorded as around or below 10,000. In a series of more than 1,800 consecutive operative patients having acute, suppurative appendicitis, diagnosed histopathologically, that I have studied, it was found that in more than 11 per cent the total count was 10,000 or less. If such a total count is accepted as diagnostic or as a criterion for surgical operation, these patients are without a friend at court. For a leukocyte count to be of value, there must be an estimation of polymorphonuclear neutrophil percentage to determine the presence or absence of infection, combined with a determination of the total number of leukocytes to weigh the patient's resistance, if infection is present. Our members are not wholly responsible for many deaths from appendicitis. The individual member of the population at large has an obligation in combating his or her disease. We must accept the responsibility for educating the public that when one has a bellyache, one must not attempt to freeze or cook the pain out. It is not to be treated by poultices, plasters or adjustments, pain relieving drugs, food or drink. Purgatives, laxatives or cathartics are not to be taken. If that bellyache lasts for two

hours or longer, a competent physician is to be called and given full responsibility. Our profession and the public must be emphatically told that for acute appendicitis there is only one route, the surgical one, and that delay is dangerous.

Dr. J. SHELTON HORSLEY, Richmond, Va.: Dr. Neal has made a very important contribution to the discussion of this subject. I have not infrequently seen, as he has said, a case of ruptured, gangrenous appendix, with a leukopenia. That is the exception, but the laboratory man should not bear the brunt of this. It is like taking the temperature of a patient. You can't make a diagnosis solely on temperature, but, associating it with other symptoms, it is very helpful. Diffuse peritonitis and spreading peritonitis are merely different names for the same thing. There was only one death in spreading or diffuse peritonitis, and that was of a patient with a gangrenous loop of bowel which had to be resected. Our records show the results. We have had many patients recover who were very ill of the type that formerly on the old treatment usually died. In regard to the intravenous administration of fluid Dr. Collier has done more than any one else to show the importance of treating dehydration. The so-called intravenous drip is extremely dangerous, as has been explained in our paper. Unless all of these five points are followed, one should not operate at once on every patient or always take out the appendix. But when suction is used constantly the adhesions may be broken up, not freely, but enough to remove the appendix in every case, and then the complications are less. In this series of nearly a thousand cases we have had not a single case of subdiaphragmatic abscess. When an appendical abscess is merely drained and the patient sent home, the patient may or may not come back and frequently does not come back until there is another abscess, and what will one do then, keep on opening it? The only real test of new procedures is the death rate and the morbidity. We frequently have cases that have been treated elsewhere; in some of them an appendical abscess has been drained, and some have been treated medically. In every case that we have, whether there is diffuse or spreading peritonitis or if the patient seems moribund, the patient is operated on immediately, day or night. So our report represents every case we have. No one is permitted to die medically.

Dr. A. H. AARON, Buffalo: We are dealing with one phase of the subject, diffuse peritonitis resulting from ruptured appendicitis. That confusion exists with regard to the treatment of ruptured appendicitis is evidenced by the following: Recently a group of senior students heard a presentation on the treatment of peritonitis following a ruptured appendix in which the speaker was quite clear that he was discussing only diffuse peritonitis of several days' duration. Nevertheless the senior students when asked the question "If you were entirely responsible for the care of a person whom you saw at 8 o'clock in the morning and your diagnosis was a possible acute appendicitis but for some reason decided to delay surgery and you returned at 4 o'clock in the afternoon, at which time in your opinion the appendix had ruptured, what would you do?" to our consternation said they would not operate but would treat the peritonitis. If there was one person who required surgery, it was this individual. Sir William Osler said years ago "There is no medical treatment of acute appendicitis." This still holds good. There is a medical preparation during the period of deferment of surgery for people with peritonitis, but there is nothing here that should be carried away, leaving in our minds an idea of delaying for one minute surgical intervention in the treatment of appendicitis. The treatment of this condition must be individualized, but I am certain of this one point: We must not have any misconception of what we are discussing. We are talking about diffuse peritonitis, not spreading peritonitis. Why do I believe in this modification of the treatment? Because the people live, as you saw, many days more than they did in our early group of peritonitis patients, who died within two or three days after they came to the hospital. In other words, we prolonged the life of a person with peritonitis to the extent of almost twelve days, in contradistinction to our early group of about three or four days, thus giving the patient an opportunity to develop and utilize his own protective mechanism to bring about recovery.

TUBERCULOSIS OF THE KNEE IN INFANCY AND CHILDHOOD

FRANCIS M. McKEEVER, M.D.

LOS ANGELES

No controversy exists concerning the treatment of tuberculosis of the knee joint in the adult. The value of surgical procedures to produce femorotibial synostosis in the general management of a tuberculous knee in the period from young adult life to middle age is no longer debatable.

For the aged there is also reasonable agreement that amputation at the thigh is the logical procedure.

The highest incidence of tuberculosis of the knee joint is, however, in infancy and childhood. It is in the years of growth, while epiphyseal cartilages are still present, that there is a lack of agreement as to the place of surgical measures in the treatment of this condition.

During the period from birth to epiphyseal closure, any surgical measure which encroaches on the articular portions of the tibia and femur has been looked on with distrust by the majority of surgeons. Girdlestone,¹ after circularizing fifty-five orthopedic surgeons in Great Britain, continental Europe and North America, stated that the operation of resection for arthrodesis should not be performed before the age of 15. Calvé² has expressed the majority opinion in the terse sentence "One commits a grievous blunder in resecting the knee of an infant."

The protagonists of operations to produce an arthrodesis of the knee in infancy and childhood have been few in the last forty years. They are, for the most part, surgeons in the British Isles. Sir William Thompson,³ writing in 1905 after thirty years' experience with the operation of resection, remained a staunch advocate of early surgical arthrodesis regardless of age. Sir Harold Stiles⁴ in 1912, after a careful study of the end results in thirty cases followed for several years, advised resection aimed at producing bony ankylosis in this age group and condemned all surgical intervention which did not have this end. Sixty-two per cent of his patients were subjected to ankylosing operations before the age of 6 years and 100 per cent prior to the age of 12 years. Despite Stiles's good end results, resection of the knee in children was looked on with disfavor through the next quarter century.

Tregubov,⁵ analyzing the trend of opinion in 1937, found most surgeons still prejudiced against this type of operation. At this time he mentioned only Maffei and Kornev as approving of resection of the knee prior to the age of 12 years. The author himself leans slightly toward the procedure and has tried resection in a few children.

Those who advocate withholding from the infant a procedure which has proved of definite value to the adult with the same disease do so on two grounds: 1. Tuberculosis of the knee in the child heals under conservative treatment. 2. The shortening and deformity

resulting from resection in the child are too crippling to justify the procedure. There are, however, no convincing statistics that proved tuberculosis of the knee in the infant and the child heals spontaneously or differs in its clinical course from tuberculosis of the knee in later years.

The shocking character of the deformities resulting from the old time massive excisions is undoubtedly responsible for the second objection.

Despite the many defenders of conservative treatment for the child, there are many evidences of dissatisfaction with this policy of appeasement. This is attested by the constant appearance of compromising surgical procedures which leave unblemished the articular cartilages of the knee joint, such as the Robertson-

Lavalle⁶ operation, directed at increasing circulation in the tuberculous area; the femur-patella-tibia arthrodesis of Delehay;⁷ the "clavettage" of Yvin;⁸ synovectomy, and lumbar sympathectomy. The development of these procedures and their acceptance for trial by surgeons indicate that the results of purely conservative treatment of tuberculosis of the knee joint in the child have not been entirely satisfactory.

PATIENTS STUDIED

Forty-seven patients were studied, all suffering from tuberculosis of the knee, proved to be that disease and no other by the recovery from the knee of either tubercle bacilli or tissue with the typical microscopic picture of tuberculosis. These patients were studied to determine the results of conservative treatment and of operative treatment directed toward producing a femorotibial synostosis. Under conservative treatment are included traction, the use of casts or braces and all operative measures which do not remove the articular cartilage from the adjacent surfaces of the femur and tibia, such as synovectomy, extra-articular excocleation of a tuberculous focus in the bone, lumbar sympathectomy and extra-articular fusions.

Under surgical treatment are included all operations designed to produce bony ankylosis between the femur and the tibia. The initial surgical procedure in all cases consisted of a removal of the easily available synovial membrane in the joint and suprapatellar pouch. The articular cartilage was removed from the ends of the femur and tibia until the cancellous bone of the ossification centers presented itself, the epiphysal lines being avoided. All tuberculous foci encountered were thoroughly curetted and emptied, even though they crossed the epiphysal lines. No attempt was made, however, to eradicate all disease. In none of the operations was internal fixation used to maintain position.

The age incidence of the disease in these patients is of interest with regard to treatment. Twenty-six patients, or 55 per cent, presented clinical manifestations of their illness before the fourth year of life had been completed. The remaining twenty-one, or 45 per cent, manifested their infirmity before reaching their tenth year of life. The appeasement policy of withholding resection until the completion of growth of the long bones would have required six years of treatment for the entire group and eleven years of treatment for more than 50 per cent. These children under conservative treatment, even if it had resulted in an arrest of the tuberculous process, would have grown up under the marquee of a hospital or clinic with the threat of an exacerbation hanging over them and the expectancy of a definitive surgical operation at the end of this road.

The academic question of the initial site of disease in tuberculosis of the knee has been pretty well reduced to the fact that by the time there is clinical evidence of the illness both the bone and the synovial membrane are involved. In this group of forty-seven children fifteen, or 31.9 per cent, almost a third, exhibited roentgenologically a definite bone abscess, sometimes very extensive, in either the lower end of the femur or the upper end of the tibia. This tuberculous abscess often involved both the metaphysis and the epiphysis and transgressed extensively on the epiphysal line early in the disease.

RESULTS OF CONSERVATIVE TREATMENT

A total of 137 years of conservative treatment employed for forty-six patients, or an average of three years per patient, did not result in one knee joint which did not show clinical signs of active disease or which permitted the patient to be about without apparatus of some type. The shortest period of conservative treatment was one month and the longest nine years. After various periods of appeasement it was possible either to recover tubercle bacilli from or to demonstrate the

Fig. 2.—A, large tuberculous abscess involving metaphysis and epiphyses; B, sites of fifteen bone foci in forty-seven patients.

tubercle microscopically in thirty-nine of these patients who were subjected later to resection.

Two patients died under strictly conservative treatment, one from pulmonary miliary tuberculosis after two years of the disease and the other from tuberculous meningitis after one year of the disease.

One patient, under nonsurgical treatment, came to amputation after two years of illness; in another case,

because of the extensive dissemination of tuberculosis through the soft tissues, amputation was advised but refused.

Draining sinuses developed spontaneously in five patients under conservative treatment.

Other surgical tuberculous foci developed in two patients under conservative treatment.

Fig. 3.—Resection had been performed six years before, at the age of 9 years.

Synovectomy alone was resorted to twice without influence on the course of the pathologic process.

Lumbar sympathectomy was employed twice. In both patients the clinical signs of activity seemed to increase rapidly. Whether this resulted from the compromising surgical intervention or occurred in spite of it is conjectural.

Extra-articular arthrodesis by means of lateral grafts was carried out in one case with the production of a structural disturbance in the femoral and tibial epiphyses and a severe flexion deformity of the knee. The disease, however, was not arrested.

One child was cured by conservative surgical treatment, and eight years after the extra-articular excochleation of a tuberculous abscess in the tibial epiphysis had a knee joint with normal motion and no clinical or roentgenographic evidence of tuberculosis. Excochleation was used in all in six cases, but in five, despite the improvement in the bone focus, the tuberculous process extended into the knee joint.

RESECTION

Thirty-nine patients were subjected to an "economical resection" aimed at producing a femorotibial synostosis. The majority of the resections were carried out between the sixth and eighth years, thirteen patients being operated on in this interval. On the oldest the operation was performed in the tenth year of life and on the youngest at the age of 17 months. The latter operation failed completely, resulting in motion. Activity of the disease continued and the knee was finally arthrodesed by a second operation in the tenth year. Two of these patients died as a direct result of the operation.

One, a 7 year old boy, died suddenly at operation, shortly after the removal of the tourniquet. The oper-

ation was not prolonged and his condition was good throughout. Autopsy revealed a pulmonary embolus. The other, a boy of 3½ years, died ten days postoperatively, with an extensive cellulitis involving the entire thigh, and a blood culture showed *Streptococcus haemolyticus*. He was subjected to resection two weeks after a biopsy. The biopsy incision was not soundly healed and gaped slightly with granulation tissue. This death might have been avoided had sufficient time been permitted to elapse for the biopsy wound to heal.

The mortality of the entire group of patients was 8.5 per cent. The mortality from resection alone was 5.1 per cent.

RESULTS

Of the thirty-seven patients who survived resection it was possible to trace thirty-four for from one and a half to thirteen years. At the time of the study of end results 42.4 per cent were over 14 years of age, so that little chance for further disturbance of growth remained.

Of the thirty-four patients whom it was possible to follow, thirty-one, or 90 per cent, were in excellent general health. One patient, at the age of 17, despite the fact that his knee had been solid for thirteen years, had active apical tuberculosis and calcification in one kidney, with recurrent hematuria. This kidney was assumed to be tuberculous. Another adolescent, at the age of 15, whose knee had been solidly ankylosed for five years and gave absolutely no evidence of inflammation, was suffering from minimal active pulmonary tuberculosis.

Fig. 4.—The patient whose roentgenogram is shown in figure 3 at the age of 15 with the leg 3.8 cm. short.

These instances of reactivation of pulmonary foci are in keeping with the idea of phthisiologists that late adolescence is a dangerous period. A child of 10 whose ankylosed knee was the site of draining tuberculous osteomyelitis was undernourished but had no other demonstrable tuberculous lesions. None had come to amputation. None had had any other joints involved.

STATUS OF THE KNEE JOINT

Thirty-three, or 97 per cent, of the resected knee joints were solid clinically and by roentgen examination showed trabeculae bridging from the femur to the tibia. One knee exhibited a definite pseudarthrosis by roentgenogram and presented a few degrees of motion after the initial operation. Another knee, although pre-

Fig. 5.—Resection had been performed thirteen years before, at the age of 4 years.

senting a solid bony fusion, had clinical evidence of activity and showed on roentgen examination the presence of a tuberculous osteomyelitis in the femoral condyles and tibial tuberosities. This was the only patient with a drainage sinus after operative intervention.

Of the thirty-three patients in whom fusion was successfully accomplished, it resulted after one operation in twenty-seven, or 82 per cent. Three patients, or 9 per cent, required two operations to produce arthrodesis. One of these was a child operated on at the age of 17 months who had a large caseous abscess in the upper end of the tibia. The operation did not produce ankylosis, but this was successfully accomplished at a second operation, performed in the patient's tenth year. The other patients requiring a second operation were a girl operated on first at the age of 5 and a boy operated on at the age of 4½ years. In neither instance was there any specific reason for the failure of the first operation to result in a fusion.

In two cases, or 6.0 per cent, three operations were required to ankylose the knee. In both the failure was due in the first operation to faulty apposition and in the second to an incomplete procedure. The initial resection was carried out in one instance at the age of 3½ years and in the other at the age of 7 years.

In one case, in which four operations were required before a fusion was accomplished, the first attempt was made at the age of 5. The difficulty was plainly due to

very destructive disease. Although the knee joint was eventually ankylosed, tuberculous osteomyelitis with draining sinuses still persists.

Two patients were operated on at the time the knee presented draining sinuses of long duration; in each case fusion resulted from the first operation with no complications.

Thus it appears that with tuberculosis of the knee in infants and children the chance that fusion will result from a single operation is as favorable as it is with tuberculosis in any other joint at any age, and possibly more so.

SHORTENING OF THE EXTREMITY

In determining the amount of shortening, teleroentgenograms were obtained of all patients. The condition of the epiphysal lines was studied by a comparison of roentgenograms of the arthrodesed knee with similar views of the normal knee. In the classification of the resulting degrees of shortening, the condition of the epiphysal lines was taken into consideration if the age of epiphysal closure had not been reached.

Interrogation of the patients revealed that none wore a shoe elevation adequate to compensate entirely for the actual shortening. Many had tried to but after years of experimentation found that with the stiff knee their gait was more comfortable and appeared more nearly normal with a shoe elevation which failed to compensate for the actual shortening by from 2 to 4 cm.

In the qualification of the results as far as disturbances in longitudinal growth were concerned, all patients who had not yet reached the age of epiphysal closure and whose epiphysal lines showed evidence of departure from the normal were classified as having "severe shortening," even though at the time of examination their

Fig. 6.—The patient whose roentgenogram is shown in figure 4 at the age of 17 with the leg 6 cm. short.

actual shortening was less than 5 cm. Patients in whom the epiphysal lines were normal and who had 5 cm. or less of shortening were classified as showing good results in this regard.

In one case, or 3.0 per cent, the arthrodesed leg was 2.5 cm. longer than the normal leg. The child was, however, only 8 years of age, and the interval since operation had been only one and a half years. Although the

epiphysial lines were normal, it is probable that the ultimate result will be a slightly shortened leg.

In thirty-two cases the average shortening of the surgically treated leg was 4.4 cm. The most severely shortened extremity was that of a 16 year old boy who had been subjected to resection nine years previously, at the age of 7. The diseased leg was 12 cm. (5 inches)

TABLE 1.—Disturbances of Longitudinal Growth

Case	Age, Yr.	Interval Since Re-section, Difference, Yr. Cm.		Epiphysial Lines
Lengthening				
1. F. G.	7½	1½	2.5	Normal
Severe Shortening				
1. R. C.	16	9	12	Closed

21. E. R.	11	5½	0.5	Normal
22. B. D.	10	3	0.2	Normal

short. The same patient had had a 55 degree genu recurvatum corrected at the age of 13. This deformity had partially recurred. He walked well with a 7 cm. elevation on the heel and sole of his shoe.

Ten patients in all, or 30.3 per cent, of those subjected to resection showed severe shortening or else the condition of their epiphyses indicated that shortening out of proportion to a satisfactory leg was to be anticipated.

Two of these patients had suffered definite injuries to the epiphyses prior to the operation of resection. In a 12 year old boy who showed a 10 cm. shortening five years after fusion of the knee, the lower femoral epiphyses had been dislocated and severely crushed by a manipulation to correct a flexion deformity. In a 15 year old girl, in whom the inequality of the legs had been held down to 6.5 cm. by epiphysial arrests on the normal leg, both the femoral and the tibial epiphyses had been badly damaged by an attempt at extra-articular arthrodesis which was done before the resection.

Three other children, who showed shortening of 10.5 cm., 5 cm. and 6.5 cm., respectively, and who, because of their remoteness from adult bone age and the condition of their epiphyses, were expected to have further shortening, demonstrated the progress of very active disease in which there is extensive caseation of bone. In one case four operations were necessary to produce femorotibial continuity, and even after fusion the knee

continued to drain. In another, two resection operations were necessary to produce ankylosis. In the third, although arthrodesis was accomplished in one operation, there had been a large caseous abscess in the upper end of the tibia prior to resection, which had destroyed part of the epiphysial line.

A 16 year old boy who had undergone fusion at the age of 10 years showed 7 cm. of shortening. At the time of fusion his femoral epiphysis was already partially closed by the disease. Further shortening was not anticipated.

An 8 year old child who was first operated on at the age of 5 exhibited 8 cm. of shortening and was expected to show more as the outer half of the femoral and the inner half of the tibial epiphysis were closed. This child was the victim of poor surgical intervention; at the first resection only slight apposition of the femur and tibia was obtained, and three operations were required before bony fusion was obtained.

In three patients, who were subjected to resection at the age of 4, 7 and 8½ years, respectively, there was more than 5 cm. of difference in the length of the legs. A 17 year old boy thirteen years after resection had a leg 6 cm. short. A 16 year old boy nine years after ankylosis had 12 cm. of shortening in the treated leg. A 20 year old girl thirteen years subsequent to resection showed one leg 9.5 cm. short. Bony ankylosis in all these patients resulted after a single operation, and no explanation of this discrepancy other than the result of the operation was evident. Epiphysial arrest was not employed on the well leg in these patients or the distressing disproportion might have been avoided.

Twenty-three patients, or 70 per cent of those subjected to resection, exhibited shortening of less than 5 cm. and had epiphysial lines which were comparable in clarity to the epiphysial lines about the normal knee. Ten of these twenty-three patients had shortening of less than 2.5 cm.

TABLE 2.—Directional Aberrations

From these figures it would not seem that the danger of extreme shortening is a legitimate objection to the procedure of economical resection of the knee in children. If the operation is carried out early, the timely application of epiphysial arrests to the well leg when the epiphyses of the diseased leg are badly damaged should hold the disproportion within reasonable limits. In the majority of children this additional surgical intervention to insure against too great a disproportion will not be necessary.

DIRECTIONAL ABERRATION OF THE EXTREMITY

The directional aberrations of growth occurring after the operation of economical resection were, in the order of their frequency, (1) flexion deformity, (2) genu valgum, (3) genu varum, (4) torsion of the tibia on the femur and (5) genu recurvatum. These occurred sometimes singly and sometimes in combination, the most frequent combination being flexion and genu varum.

Flexion of the knee of less than 25 degrees did not seem to be disadvantageous to the patient and was not tabulated as a deformity.

Flexion of more than 25 degrees resulted in seven cases. The most marked flexion deformity occurred in a case in which resection was done at the age of 9 and the epiphysis had been injured by a prior attempt at extra-articular arthrodesis. This deformity, of 60 degrees, was easily corrected by osteotomy at the age of 12. The leg has remained well aligned, although slight flexion has recurred since the correction. Three patients had a flexion deformity of 45 degrees. One of these, a girl of 20, who worked as a secretary, did not desire the leg straightened. The extremity of a 6½ year old patient was corrected by an osteotomy, and at a later date another osteotomy will in all probability be necessary, as his epiphyses are seriously damaged by disease. The third, a boy of 12, will probably desire a corrective procedure in the next three years.

A 16 year old patient whose knee had been solidly arthrodesed for six years presented 40 degrees of flexion in combination with moderate varus and torsion and should have the extremity revised. Prior to resection a portion of the tibial epiphysis had been destroyed by tuberculosis. Two other children, aged 10 and 11 years, presented deformities of 30 and 35 degrees. They may need osteotomies in later years, but as they are both girls this is doubtful.

The flexion deformities which resulted in these cases seemed to progress rapidly in the first two years after operation despite adequate immobilization and usually reached their maximum in this period.

A genu valgum deformity occurred in six patients. In one, a child of 9½ years of age, it reached the extent of 40 degrees. In this patient disease had continued to destroy the lateral portion of the femoral epiphysis after the initial resection, and three operations were necessary to produce ankylosis. In another child 20 degrees of valgus was present, with 45 degrees of flexion and 6.5 cm. of shortening. These aberrations were corrected by supracondylar osteotomy. One other child has a knock knee deformity of 20 degrees and will require an osteotomy, as she still has seven years to grow. The three remaining valgus deformities are very mild, two being of 10 degrees and one of 5 degrees, and probably will not require revision.

Five patients exhibited a varus deviation. The greatest bow leg deformity was of 20 degrees in a 14 year old girl. It was associated with internal torsion of the tibia on the femur so that in walking the foot pointed inward about 25 degrees. The patient did not wish it corrected. The four other bow leg deformities were of 15, 12, 10 and 10 degrees, and except for one did not annoy the patient. In this instance the bowing was associated with 40 degrees of flexion.

Internal torsion of the tibia on the femur was present in four cases, but in only one was it of any consequence. Torsion was usually associated with genu varum.

Genu recurvatum occurred three times. In one patient it reached 55 degrees and presented a very unsightly

deformity. In two other patients the angle of hyperextension was 20 degrees. All desired relief from the deformity, and all had it corrected by osteotomy. A correction carried out in a girl at the age of 17 had remained perfectly corrected three years later. Two other patients, operated on at the age of 12 and 13, had suffered a slight recurrence of the deformity.

The extremities of seventeen patients had flexion within the optimum of 25 degrees and presented no evidence of varus, valgus or torsion. Five other patients had extremities which showed flexion within the optimum angle but presented a very slight variation in valgus or varus which neither disfigured nor interfered at all with function. These legs will not require osteotomy.

Six patients had had an osteotomy to alleviate a troublesome deformity. Four more patients will probably require correction by osteotomy at a later date and two patients will probably need a second osteotomy.

Of the patients, 66⅔ per cent had no appreciable directional aberration of the extremity; 18.2 per cent had deformities requiring a corrective osteotomy; 15.1 per cent will probably desire an osteotomy to correct a deformity, and two, or 6.0 per cent, who have already undergone one revision may require a second osteotomy because of recurrence of the deformity due to the poor condition of the epiphyses.

On all patients on whom osteotomy had been carried out the operation was done above or below the ankylosed joint. In none was there any reactivation of the tuberculosis.

SUMMARY

For forty-seven patients in the first ten years of life suffering from proved tuberculosis of the knee joint, the most frequent age of onset was found to be within the first four years.

Fifteen patients, or 31.9 per cent, presented a bone abscess in the metaphysial or epiphysial region of the tibia or the femur early in the disease.

One patient remained well, with a normal knee joint, for eight years after extra-articular excocleation of an osseous focus. In five other patients this procedure failed.

Conservative treatment, or surgical procedures short of economical resection, accomplished no satisfactory results in the remaining forty-six patients.

Economical resection healed the tuberculosis in thirty-two of thirty-four patients, or 94.1 per cent, whom it was possible to follow for from one and a half to thirteen years.

The knee joint of a child ankyloses very readily after resection, and the percentage of successful fusions resulting from a single operation is as high as that for ankylosing operations on any other joint.

Extreme shortening after economical resection in infancy and childhood is not the rule; any marked degree occurred in only 30 per cent of the patients. In these it usually resulted from causes extraneous to the resection.

Severe aberrations of directional growth were associated in most instances with previous damage to the epiphyses. They occurred in only 33⅓ per cent of the patients. Moreover, in these they were readily correctable by osteotomy.

CONCLUSION

From this evidence it seems reasonable to conclude that economical resection of the knee is not contraindicated prior to epiphysial closure. Therefore this

procedure should not be withheld until the age of 15 from children suffering from tuberculosis of the knee joint. Rather it should be practiced early after a period of conservative treatment adequate to cause an abatement of signs and symptoms of acute disease.

ABSTRACT OF DISCUSSION

DR. W. P. BLOUNT, Milwaukee: Dr. McKeever has given a convincing argument in favor of arthrodesis or resection of tuberculous knees of older children. The 20 per cent of his cases in which reoperation was required encourage those of us who have had the same experience of failure of fusion at the first operation. He has reopened a subject which has been controversial for years. The proponents of the conservative method of treatment, notably Rollier and men in various European clinics, held that arthrodesis of the knee was never necessary. Ten years ago Rollier was advocating conservative treatment, but I know that a surgeon on his staff was doing arthrodeses in selected cases. Perhaps he has come by now to arthrodesis of the knee in children also. There is no argument in this country as to whether or not this procedure is indicated in older children. The earlier claims of success with conservative methods were artificially colored by the inclusion of nontuberculous knees. On the other hand, the proponents of fusion in infancy are equally incredible. I have had no hesitancy in arthrodesing knees in children over 8 years of age. I prefer to wait a little longer if there is no clearcut indication for early fusion. Most men will agree with this, and the real question is what to do with the very young children with tuberculous knees. It is interesting that in 55 per cent of Dr. McKeever's cases the disease was present before the age of 4. At Milwaukee Children's Hospital I found that in most of the cases the disease was evident before 3 and that half of the children were less than 3 years old at the time they came in for treatment.

DR. R. B. OSGOOD, Boston: I know very little about tuberculosis of the knee. It is a disappearing disease in New England. The tendency, perhaps not the rule, with us has been to delay any attempts at fusion, if we thought it was indicated, until the age of 5 years. With us growth deformity and shortening have not been a negligible factor. Dr. McKeever's paper is very convincing as to the value of arthrodesis from the medical, economic and social point of view, but excessive shortening and very definite operative growth deformities have occurred in his cases in something over 31 per cent, in 11 per cent operative and 20 per cent more in which he expects to operate, and the story is not finished. Surgical intervention has been necessary in about 26 per cent in extreme shortening, and then a stiff knee, after all, is a stiff knee, isn't it, and perhaps the better—but not the best of a bad bargain. When the articular cartilage is beyond repair or is evidently eroded enough so that we know a normal joint will never exist, I think we agree that our better bargain is an arthrodesis procedure. I have nothing to say against the method and I wish to compliment Dr. McKeever on his very careful and thorough and entirely judicial analysis, but I wish to remind you that in the Bible there is something about God promising to save Sodom and Gomorrah if there were—I have forgotten how many—righteous people there. Ten, we will say. They were not found, and Sodom and Gomorrah were destroyed. If we could save a few knees under favorable conditions of tuberculosis in children it would perhaps be worth while to do so. I have seen comparatively few cases of tuberculosis of the knee in early childhood, and I myself have seen only three cases of proved tuberculosis in which apparent recovery has occurred without operation for at least eight years. I can say that in these cases I have had very good luck in having recovery apparently occur with good degrees of motion, by trying to overcome atrophy without allowing the trauma of weight bearing.

DR. HALFORD HALLOCK, New York: Our experience at the New York Orthopedic Hospital has been very much the same as Dr. McKeever's. In 1915 we gave up treating tuberculosis of the knee by conservative methods because we could not obtain cures and began using fusion. Since that time our series has run to 200 or 300 cases, about 70 per cent of which have

been proved to be tuberculous. Over 90 per cent became fused by the first operation. The knee joint is one of the easier ones to fuse and we have had but little trouble in obtaining arthrodesis. We have also had some trouble with shortening. I should say that perhaps 10 or 15 per cent of our cases have ended with considerable shortening, as in Dr. McKeever's 30 per cent. We believe that the probable cause was the fact that operation was delayed too long. The disease had already produced disturbances or destruction of the epiphyseal lines before fusion was performed. We feel that, in order to prevent all this shortening, arthrodesis must be done before the disease has partially or completely destroyed the epiphyseal lines. I should like to say something about deformities in the younger children. It is our custom in children to fuse the knees at 180 degrees, because we have found that otherwise flexion deformities may occur through the distal epiphyseal line of the femur. We also use braces for a number of years after fusion in very young children in order to prevent slipping through this epiphyseal area. I should like to ask whether Dr. McKeever has fused the knee joint of all his younger patients in from 10 to 25 degrees of flexion. I still believe that tuberculosis of the knee should be operated on even at an early age and that fusion is the only method which will give a large percentage of cures in these cases. So far I have never seen a recurrence of tuberculosis in a knee that became fused and that has been since 1915.

DR. FRANK R. OBER, Boston: There are some cases of tuberculosis of the knee in which complete recovery occurs without any operation, but these are the cases in which the tuberculous process does not go into the knee joint. It does not extend through the epiphysis but does extend laterally and decompresses itself through the side of the bone, either laterally or medially. In such cases healing takes place without any disturbance to the knee joint whatever and fusion should not be done on such patients. Dr. McKeever had six cases of forty-nine which showed no fusion after one or more operations. At the New England Peabody Home, where we have a large number of children affected with bone and joint tuberculosis, we feel that unsuccessful fusions are not always the result of faulty technic but are often due to other conditions which result from a general tuberculous process. All of these cases are studied thoroughly by a pediatrician. Roentgenograms of the chest are taken and if there is any sign of active pulmonary lesions we believe that operation on a tuberculous joint is contraindicated. Furthermore, if the child has a high monocyte count and a low lymphocyte count and fusion is done, the fusion tends to melt down and there is a recurrence. This monocyte-lymphocyte ratio, when high, shows that there is too much activity of the tuberculous process and we have learned not to operate until the ratio is normal.

DR. FRANCIS M. McKEEVER, Los Angeles: In answer to the question about the position in which these knees were placed postoperatively, most of them were placed within 10 degrees of a straight angle. Arthrodesing a tuberculous knee in a child is not, of course, the ideal procedure; however, as in some questions of government and also in medicine, it is a question of the lesser of two evils and I believe that this procedure is better than going on with the malady. In our experience the tuberculous knees in children have not done as well as they have in New England.

What Constitutes Normality?—Medical men are insufficiently conversant with what constitutes normality, or the range of normality, in the human being. They regard as pathological many phenomena which are in reality not only compatible with health, but are actually physiological. It is of much consequence that this argument should be brought home. . . . Take a very simple case: Stroke the back of a normal healthy young subject and watch the vascular reaction in the skin; the line pressed and the surrounding skin displays after a while a red line; maybe it soon becomes surrounded by an area of blanching, maybe a line of blanching alone appears. These reactions, perfectly healthy reactions as they are, have been used, are still used, and will be used for many years to come, as important signs of particular and serious disease.—Lewis, Sir Thomas: *Research in Medicine and Other Addresses*, London, H. K. Lewis & Co., Ltd., 1939.

HYPOTHYROIDISM IN THE CAUSATION OF ABORTION, ESPECIALLY OF THE "MISSED" VARIETY

E. L. KING, M.D.

AND

J. S. HERRING, M.D.

NEW ORLEANS

Whether we are entirely correct in applying the term "hypothyroidism" in each of the cases under consideration might be questioned, as the diagnosis is based chiefly on the determination of the basal metabolic rate. However, as we are concerned particularly with early pregnancy, in which indefinite manifestations such as malaise and fatigability are so common, we find that we are not in a position to base our diagnosis on the usual symptoms of hypothyroidism. It is our opinion, moreover, that the minor degrees of this state may be practically symptomless and yet may seriously affect the reproductive function. This is in accord with the views of Litzenberg and Carey,¹ who stated that "it would seem apparent that any deviation from the normal rate must be due to thyroid influence and

inasmuch as the patient usually responds to thyroid medication we have used the term 'hypothyroidism' in spite of the fact that clinicians in general seem reluctant to attach a diagnosis of hypothyroidism to a patient with low basal metabolic rate." However, as Litzenberg² later stated in Curtis's system, other endocrine factors may be involved in some patients with low basal metabolic rates. It is difficult, if not impossible, to segregate such patients from those in whom the abnormality is of thyroid origin; we feel, moreover, that the number of such patients is small and hence that it is proper to group all patients with low basal metabolic rates together.

A considerable amount of investigation has been conducted in the field of the basal metabolism of pregnant women, but emphasis has been placed chiefly on the latter half of pregnancy. Only a few reports of determinations of the basal metabolism in early pregnancy are to be found in the literature. The consensus is that in normal gestation the basal metabolic rate is

little altered in the early months and steadily rises as pregnancy advances, reaching, according to Baer³ and Cornell,⁴ a level from 25 to 35 per cent above normal at term.⁵ The Roots⁶ state that the rise in the rate is out of all proportion to the increase in the maternal weight. Sandiford and Wheeler⁷ hold that the altered production of energy in the latter part of pregnancy is due to the increased mass of active protoplasmic tissue, chiefly fetal, and not to a change in the amount of heat produced per unit volume of maternal tissue. This opinion has been reaffirmed in a later paper.⁸ Du Bois⁹ states that the metabolism averages —8 per cent early in pregnancy and mounts in a straight line to +7 per cent just before delivery (quoting the results reported by Rowe, Alcott and Mortimer¹⁰).

It is apparent, then, that one should expect approximately normal basal metabolic rates early in pregnancy and that the same criteria as to what may be considered abnormal rates are to be observed. Litzenberg and Carey¹ class obstetric patients with rates of —10 or below as hypothyroid. Sloan,¹¹ writing of hypothyroidism in general, feels that there are many persons with rates of —10 or even less and other mild suggestive signs and symptoms who should be classed as hypothyroid. Sterility in women with hypothyroidism was first mentioned by Litzenberg,¹² and his observation has been abundantly confirmed by many other authors.

The association of a low metabolic rate in early pregnancy with an increased tendency to abortion has been noted by several writers. Litzenberg and Carey¹ report that of seventy-eight married women with a low basal rate thirty-five (or 45 per cent) were absolutely sterile, six had had abortions or stillbirths (but no living children), and nine with one or more living children had also had one or more abortions or stillbirths. Besides, they found that seventeen (or 30 per cent) of fifty-two sterile women with a low basal metabolic rate conceived after treatment with thyroid extract; two of these aborted because they discontinued treatment after conception had occurred. These authors feel that a normal metabolic rate should be maintained during pregnancy. Huntington¹³ reported a case in which there had been three pregnancies at term and then three abortions; the patient was then found to have a basal metabolic rate of —21. Another patient had had an abortion, then a full term pregnancy and then another abortion one year later, at which time the rate was —17. Abruzzese¹⁴

found that of thirty aborting women five had a low basal metabolic rate and eleven an abnormally high rate. Taussig¹⁵ states that if the rate is between -10 and -30 thyroid extract should be given and will often prove to be a factor in the prevention of abortion. However, it does not appear that the importance of hypothyroidism as a factor in the causation of fetal death and subsequent abortion has been sufficiently stressed in medical literature; hence we feel that a presentation of our experience may be of interest.

This report represents a study of the basal metabolic rate of 150 pregnant women, all private patients. The readings were taken in the early months of pregnancy except in two cases, in which it was first taken after miscarriage had occurred. The association of abortion with rather marked hypothyroidism had previously been noted in several instances. We began to determine the basal metabolic rate in all cases of early pregnancy except those of multiparas with clear records, and we have recently decided to include them as well. We have not made it a practice to make determinations for women first consulting us in the latter half of pregnancy, as it appears that any interference with gestation ascribable to the thyroid deficiency will practically always develop during the first four months. It might be advisable to test these patients as well; in one patient seen in consultation near the end of pregnancy the intra-uterine fetal death could be ascribed only to hypothyroidism, the rate being -16 .

Of these 150 women, seventeen were found to be hyperthyroid (basal metabolic rate $+10$ or over), seventy-two had normal readings and sixty-one (or 40.6 per cent) were hypothyroid. Of the seventeen in the first group, five were multiparas; three of these had aborted in a previous pregnancy. One of these hyperthyroid patients aborted while under our observation. Of the seventy-two women with normal rates, ten were multiparas with four previous miscarriages. There was only one abortion in this group of seventy-two; eight threatened abortions were averted. However, the patients with rates between -6 and -9 were given small doses of thyroid extract prophylactically, especially if they had aborted in previous pregnancies. We feel that this was a factor in reducing the number of abortions; it will be noted that there were four previous abortions but only one in the present series of pregnancies. Of the sixty-one women in the hypothyroid group, eleven were multiparas who had had thirteen previous miscarriages. There were eight abortions. Two of the women had been adequately treated, while in six cases the hypothyroidism was not detected promptly because the patient was not seen sufficiently early, there was little or no treatment and abortion occurred. For the other patients of this group the diagnosis was made early, treatment with thyroid extract was instituted promptly and the pregnancy went to term. There were eleven cases of threatened abortion. We feel that the fetal loss would otherwise have been much greater, especially since in some instances the rate was as low as -20 to -23 .

Some of these hypothyroid patients presented clinical experiences which seem to us to substantiate our contentions very definitely. One woman had had a thyroidectomy at 17. Her first pregnancy resulted in intra-uterine fetal death and miscarriage at the sixth month. The next baby was carried to term and born

alive; the mother took thyroid extract regularly during this pregnancy. After this she was extremely remiss regarding treatment, and the basal metabolic rate varied between -16 and -22 on the rare occasions when she reported for examination. Since this term pregnancy in 1934, she has had three spontaneous miscarriages at from two to three months, all due, we are sure, to her failure to continue systematic and adequate thyroid dosage. Another patient was first seen at two and one-half months. A threatened miscarriage developed a few days later but abortion was averted. The basal metabolic rate was -10 ; thyroid extract was administered and she went to term. The administration of thyroid extract was discontinued and nine months later she aborted at six weeks (there was no embryo in the intact sac); the basal metabolic rate was -12 . The thyroid treatment was continued. She became pregnant again five months later and was delivered at term. Another patient, after being delivered at term in 1927, has had eight spontaneous abortions at from two and one-half to three months' gestation. Her basal metabolic rate in May 1937 was -13 , while that of her husband was -6 . They have not been seen since that date. A fourth woman miscarried at five months in 1925,

delivered at term in 1926, miscarried at six months in 1934 and aborted at between six and eight weeks in 1935. In June 1936 she became pregnant again and was first seen by one of us in September, at which time the basal metabolic rate was -17 . Thyroid extract 2 grains (0.13 Gm.) a day was administered and she was delivered of a living child at term.

The term "missed abortion" refers to the retention of the intact products of conception in the uterus for a considerable period after death of the ovum. There is some difference of opinion as to the length of this time interval. Litzenberg placed it at two months or more, while Streeter (quoted by Taussig¹⁵) believes that from four to six weeks usually elapses between the death of the fetus and its expulsion. Taussig¹⁶ believes that all cases in which the complete ovisac is retained after death of the fetus or embryo should be included under this classification. Hence the reported frequency of this condition will vary according to the varying ideas of the authors as to the precise definition of the term. We are inclined to agree with Taussig that no hard and fast rule can be adopted; however, the fetal death will usually have occurred from six to eight weeks before the diagnosis is definitely made or the mass is expelled. In this series there were three previous missed abortions and three in patients under our

15. Taussig, F. L.: Abortions Spontaneously Induced, St. Louis, C. V. Mosby Company, 1936, p. 104.

16. Taussig,¹⁵ p. 246.

observation. In addition there were two women (one the thyroidectomized patient before mentioned) in whom fetal death occurred rather late, at the sixth month and at the eighth. Both women were noticeably hypothyroid clinically and their rates varied between -16 and -25 . We therefore feel justified in considering the hypothyroid state an important etiologic factor in the missed abortion.

We believe that hypothyroidism is of rather frequent occurrence in our section of the country and that its frequency is therefore increased in pregnancy as well. Mahorner¹⁷ is of the same opinion and informs us that this condition is more common with us than in some other localities. We shall not attempt to theorize as to the factors which might be responsible.

We feel justified in concluding, therefore, that hypothyroidism of mild or moderate degree is a fairly common complication of pregnancy. The severer types, particularly when associated with the same condition in the husband, will be found to be productive of sterility. It therefore appears logical to determine the basal metabolic rate as a routine in early pregnancy and to institute proper treatment when the rate is found to be low. We believe that by so doing we have been able to carry many patients to term who might otherwise have aborted because of the hypothyroidism.

SUMMARY OF THREE ILLUSTRATIVE CASES

CASE 1.—Mrs. B. had had a thyroidectomy at 17. In her first pregnancy, intra-uterine fetal death occurred at the sixth month. In her second pregnancy she was treated with thyroid, and she was delivered at term. In the third, fourth and fifth pregnancies she had little or no treatment; the basal metabolic rate varied from -17 to -22 and all terminated in miscarriage.

CASE 2.—In the first pregnancy there was a threatened miscarriage; the basal metabolic rate was -10 , and delivery took place at term. The second pregnancy ended in abortion at the sixth week; there had been no treatment, and the basal metabolic rate was -12 . During the third pregnancy the patient was treated and she was delivered at term.

CASE 3.—A delivery at term took place in 1929, and there have been eight miscarriages since. The wife's basal metabolic rate was -12 and the husband's -9.6 .

ABSTRACT OF DISCUSSION

DR. J. C. LITZENBERG, Minneapolis: Moll asked his students when they went out into practice to send him the products of abortion so that he could study them embryologically. He determined the age of the ovum by embryologic methods without a knowledge of the menstrual history. He first determined the embryologic age and then, by the case history, the menstrual age. He found that the embryologic age and the menstrual age were six weeks apart; that the embryo or fetus was generally six weeks younger than the menstrual age would indicate. Hence the fetus had died six weeks before it was aborted. Moll also brought out another important point which has been subsequently elaborated and discussed by Streeter and his colleagues, and that is that most abortions are due to the death of the fetus and that the cause of this death is defective germ plasma. Now defective germ plasma is not a microscopic determination. As Streeter gives the definition, it is not a study of the histologic type or histologic-pathologic conditions in the fetus, but the fetus or embryo, as the result of defective germ plasma, simply does not develop and it dies and an abortion results. The old ideas of trauma and the like are of minor significance. In my first two papers, the second with my colleague Dr. Carey, I found that there is an intimate relation between hypothyroidism or just low basal metabolism (I think we can continue to call it hypothyroid-

ism) and abortion. This relation, as Dr. King has quoted, we found definite in 45 per cent of all of our sterile women, i. e. 45 per cent of them had low basal metabolic rates. The fact to which I wished to call attention at that time was that moderately low rates affected conception and abortion. It was perfectly well known before that time that there was a relation between the thyroid and conception when rates were very low. Women with myxedema seldom conceived. When they conceived they would abort. But the fact to which I called attention was that a basal metabolism of very moderate degree also interfered with conception and caused abortions. There is quite a difference between the relation of basal metabolism to disease and its relation to the physiology of pregnancy. The cells of the gonads are very susceptible to deleterious influences and therefore fusion between an ovum and a sperm either one of which is below par will give an embryo that is below par, the fetus doesn't develop properly, therefore it has defective germ plasma, and it dies and an abortion occurs. We found that 45 per cent of women who were sterile had low basal metabolic rates. Furthermore, we found that 46 and a fraction per cent of all girls who had menstrual disturbances of all kinds—we made no distinction—had low basal rates. We approached the subject from another angle. Then we tried also to find out what percentage of women who had low basal metabolic rates did not conceive. The relation was quite as close, being more than 40 per cent.

DR. JESSE W. WHITE, Pueblo, Colo.: In our community in Colorado there are a great many women with a slightly lowered basal metabolic rate. About 80 per cent of those women will be relieved of the symptoms of fatigue and nervousness by the giving of desiccated thyroid. A number of women were found to be aborting apparently as a result of the hypothyroid condition, and I found also that it was a factor in the slow recovery after pregnancy. Many women who complained of excessive fatigue and inability to do their work at the usual time following delivery could be brought back to normal within a relatively short time by the giving of desiccated thyroid when the metabolic rate was low. Hunt and his associates have recently reported experimental work which shows fairly conclusively, I feel, the relationship of hypothyroidism to toxemias of pregnancy and shows how these abortions may occur. They have shown that with this hypothyroid condition there is an increase in cholesteraemia and also marked infarcts in the placenta which apparently are due to endarteritis, probably caused by the high cholesterol content in the blood. It is my opinion that practically all communities have these cases of low metabolic rate with practically no symptoms other than fatigue and sometimes nervousness and that potentially these are women who will abort or be relatively sterile. This condition is not confined to women as far as sterility is concerned, since I have had numbers of cases in which a low metabolic rate in the male was the apparent cause of a childless marriage until after desiccated thyroid had been given.

DR. FRED J. TAUSSIG, St. Louis: The time to start the treatment for the prevention of spontaneous abortion is before conception has occurred. I think if we delay treatment until after conception has occurred we shall often have an ovum that is primarily blighted and nothing that we can do will prevent the unsuccessful termination of the pregnancy at term. Treatment, however, should not be limited to a study of the thyroid function. I think pelvic factors should be taken into consideration and the other endocrine organs be given a careful review. Unfortunately there are relatively few accurate tests to determine the function of sex glands and the pituitary. Physicians depend on the basal metabolism test perhaps too much, but at any rate it is an index of thyroid deficiency, and if we include the husband as well as the wife in the preliminary treatment when there is a relatively low basal metabolism test, we shall often get a successful implantation and a development of the ovum to term. I feel also that vitamin E is a substance that seems, at least in a certain number of cases, to stimulate the development of healthy ova. For that reason, in this preliminary, preconceptional treatment I often give both husband and wife small doses of thyroid if there is a low basal rate, and also put them on a high vitamin E diet.

CRYSTALLINE INSULIN

ALEXANDER MARBLE, M.D.

AND

ILMARI VARTIAINEN, M.D.

BOSTON

"Crystalline insulin" was released for general sale in August 1938 under the name "insulin specially prepared as solution of zinc insulin crystals." However, in contrast to the other two types of insulin now commercially available, the regular type (amorphous, unmodified) and the protamine zinc insulin, its rapidity of action and duration of effect have remained controversial. In the hope of clarifying the issue, in November 1938 we undertook a comparison of the action of regular insulin (prepared from amorphous material) with that of solution of zinc insulin crystals and now present the results of the study.

In 1926 Abel¹ and his associates succeeded in obtaining insulin in crystalline form from highly purified amorphous preparations. Scott² in 1934 noted that samples of such crystalline preparations contained traces of zinc; he observed also that crystals were formed only in the presence of certain heavy metals—zinc, nickel, cobalt or cadmium. By the addition of small amounts of zinc to protamine insulin, prolongation of effect of this already slowly acting preparation was reported by Scott and Fisher;³ increased duration of action was noted also when relatively large amounts of zinc were added to regular insulin.

Sahyun⁴ stated that at pH 6.0 to 6.6 the solubility in aqueous solution of zinc insulin crystals was substantially less than that of amorphous preparations and suggested that, following subcutaneous injection, the rate of absorption of the crystalline type might be slower and its action longer than that of the amorphous variety. Clinical studies have been carried out by various groups of workers to investigate this point. The results have in most instances⁵ been interpreted as indicating that the duration of effect of a solution of zinc insulin crystals is much greater than that of insulin prepared from amorphous material. In one report recently published⁶ the authors, although recognizing

the longer action of protamine zinc insulin, speak of the crystalline type as a "long acting" insulin and state that "those diabetics transferred to crystalline insulin were better controlled than those on protamine zinc insulin alone or in combination with regular insulin." Some have stated that its length of action on the blood sugar is two or more times as great as that of insulin of amorphous type.⁷

On the other hand, the early studies of Howard and deLawder⁸ on four diabetic patients failed to show any appreciable difference in effect between insulin made from crystals (prepared in the department of pharmacology of Johns Hopkins University) and insulin made from amorphous material. From his experience with a preparation of insulin crystals (content of zinc not stated), Wilder⁹ concluded that, although its action was longer than that of insulin made from amorphous material, it was not comparable to that of protamine insulin. He stated that the duration of effect of the solution of crystals was not long enough to permit the treatment of severe diabetes with fewer than two injections a day. Myers and Perkin¹⁰ found a marked similarity between the effect of the crystalline and the amorphous types and concluded that there was little, if any, difference in the action of the two types. Sahyun¹¹ quotes Myers as stating that more recently he has observed prolongation of action following the use of a solution of zinc insulin crystals. Nelson and Dummer¹² found it impossible to control the blood sugar of children with severe diabetes during the night by the injection of a solution of crystals, either at 5 or at 9 p. m., since almost invariably attempts to control the fasting blood sugar of the following morning resulted in serious hypoglycemic attacks during the night.

Almost without exception, studies in normal animals, such as those of Blatherwick, Ewing and Bradshaw¹³ in rats, have failed to show any striking difference between the action of amorphous and crystalline preparations of insulin. It is true that Kohl¹⁴ asserted that in rabbits insulin of the crystalline type exerted a somewhat greater effect than did that of the amorphous type, but in his paper no mention was made of the amount of zinc in the preparations used. Sahyun¹⁴ has recently reported the results of comparative tests on rabbits, using thirty-three animals for each preparation tested; the average blood sugar curves obtained with the two types of insulin were very similar.

MATERIALS

Samples of "insulin specially prepared as solution of zinc insulin crystals" and of insulin prepared from amorphous material of Eli Lilly & Co. and of Frederick Stearns & Co. manufacture were used in the studies. The Lilly products were furnished us by that company

Dr. Vartiainen is the holder of a fellowship of the Finnish government. Miss Rachel M. Smith and Miss Alison T. Fernald gave technical assistance.

From the George F. Baker Clinic, Elliott P. Joslin, M.D., Medical Director, New England Deaconess Hospital.

The board of the patients, the compensation of the medical students who served as normal subjects, the cost of certain supplies and the salaries of Mrs. Rita M. Reed and Miss Frances Waterhouse, who gave technical assistance during the period of the study, were paid by Eli Lilly & Co. Part of the insulin used was purchased by funds of the United States Food and Drug Administration.

in the form of "unknowns" labeled insulin A and insulin B. Not until the study was completed were we told that insulin A was of the crystalline and B of the amorphous variety. We were assured in writing that both insulins were taken by Eli Lilly & Co. from lots prepared for distribution and actually dispensed

Chart 1 (case 1).—Blood sugar curves following single doses of insulin-Lilly (0.2 unit/Kg.). Food was withheld throughout the tests. *B*₁, amorphous, Nov. 16, 1938; *A*₂, crystalline, Nov. 21; *B*₂, amorphous, November 26; *A*₁, crystalline, December 1.
E. R., a man, aged 23.5 years, had had diabetes since September 1928. The diet during the period of study was carbohydrate 175 Gm., protein 101 Gm., fat 130 Gm. Body weight, 122 pounds (55.3 Kg.); height, 64 inches (163 cm.).

Note that in this and in the following charts the rapidity of effect of the two types of insulin was essentially the same, as evidenced by the rate of fall of the blood sugar. The two curves *B*₁ and *B*₂, showing the effect of the amorphous type, obviously differ very little from the other two curves, which give the results with the solution of zinc insulin crystals. There was, to be sure, a spread of about 50 mg. in the initial values of the four curves. This degree of variation on different test days is difficult to avoid in patients with severe diabetes. We have preferred to present the actual data rather than attempt to adjust the initial values to a uniform starting level.

commercially. The Stearns products were purchased on the open market and delivered to us by inspectors of the Boston office of the United States Food and Drug Administration. All samples used were stated by the manufacturers to contain 40 units per cubic centimeter.

In table 1 are shown the results of the analyses of the preparations used. The values for potency, nitrogen content and zinc content were furnished us by the Insulin Committee of the University of Toronto. Both Frederic Stearns & Co. and Eli Lilly & Co. supplied us with the results of their own determinations of the nitrogen and zinc content of their respective products. The values for nitrogen were in each instance almost identical with those obtained by the Insulin Committee. Those for zinc did not agree quite as closely, but the slight differences are not surprising, since the accurate determination of minute quantities of zinc is difficult; minor discrepancies between figures furnished by different laboratories must be viewed with this in mind.

In addition to the analyses for which results are shown in table 1, biologic assays of the four samples of insulin were carried out in the laboratories of the Insulin Committee, from forty-eight to eighty-two rabbits being used for each comparison. In these studies the effect on the blood sugar of each type of insulin was compared with that of the other type of the same manufacturer and in some instances with that of a preparation of insulin crystals (S-220), which, since the early part of 1936, has been the official standard

of reference for insulin supplied in the United States and Canada. The average blood sugar curves obtained showed, in the case of the products of each manufacturer, the effect of the solution of zinc insulin crystals to be almost identical with that of insulin prepared from amorphous material. That similar results have already been reported by Sahyun¹⁴ has been mentioned earlier in this paper.

CHEMICAL METHODS

The blood sugar was determined on capillary samples by the micro procedure of Folin and Malmros.¹⁵ The percentage of sugar in the urine was determined by Smith's¹⁶ modification of Benedict's method. Folin's¹⁷ micro Kjeldahl method for the determination of total nitrogen in the urine was used.

PLAN OF INVESTIGATION

Diabetic Patients.—Eight patients, four men and four women, with diabetes of moderate or severe grade served as subjects. They spent the entire period of study, from thirty-three to seventy-three days, in the hospital under conditions which were controlled as carefully as possible. All were reliable, intelligent and cooperative. Their ages ranged from 20 to 58 years. With one exception all patients had had diabetes for ten or more years; patient 3 had had the condition for 4.8 years. The details regarding individual patients are given in the legends for the various charts.

The plan of investigation was as follows: Each patient was kept on a constant, weighed diet; the

Chart 2 (case 1).—Response to insulin B (Lilly, amorphous type) and insulin A (Lilly, solution of zinc insulin crystals). As in the other charts, the broken line is used for blood sugar curves during days of maintenance on insulin of the amorphous type and the solid lines for those during days of maintenance on the solution of zinc insulin crystals. Insulin was administered at 7 a. m., 12 noon and 5 p. m. daily in the amounts indicated. In the hourly schedule that appears beneath the days of the month, 12 is used to indicate noon and 24 to indicate midnight.
It is evident that with this patient blood sugar values were somewhat lower during the period of maintenance on the solution of zinc insulin crystals. However, despite the fact that sufficient insulin was given before supper to cause low blood sugar values at 10 or 11 p. m., this dose did not prevent a rise of the blood sugar to over 200 mg. per hundred cubic centimeters by 7 a. m. the following morning. Furthermore, it is evident that glycosuria was only slightly less when the crystalline type was used. The average daily excretion of nitrogen in the urine was the same with the two types of insulin.

amount of carbohydrate ranged from 137 to 247 Gm. a day. The quantity of sugar and, in five of the eight patients, the quantity of nitrogen excreted in the urine

in twenty-four hours was determined daily. In addition, qualitative tests for sugar were carried out at 6:30, 9:30 and 11:30 a. m. and at 2:30, 4:30, 7:30 and 9:30 p. m. daily. Determinations of the capillary blood sugar were made at 7 and 11 a. m. and at 2, 5 and 10 p. m. daily throughout the study except on certain

Chart 9 (case 5).—Blood sugar curves following single doses of insulin-Lilly (0.15 unit/Kg.). Food was withheld throughout the tests. *A*₁, crystalline, Nov. 22, 1938; *B*₂, amorphous, November 29; *A*₂, crystalline, December 5; *B*₁, amorphous, December 10.

Miss E. M., aged 58.4 years, had had diabetes since July 1917. The diet during the period of study was carbohydrate 137 Gm., protein, 79 Gm., fat 98 Gm. Body weight, 120 pounds (54.4 Kg.); height, 65½ inches (166 cm.). The curves in this case were much like those in case 4 shown in chart 7. There is no doubt that the curves *A*₁ and *A*₂, obtained with the solution of zinc insulin crystals, showed not only a greater degree of fall but also a definite prolongation of effect as compared with those following insulin of the amorphous type.

special test days, when they were carried out at hourly intervals from about 8 a. m. to 11 p. m. or midnight. Almost without exception, blood was obtained from puncture of an ear lobe.

Before actual studies were begun, the diabetic condition of the patients was stabilized on the diet to be followed during the investigation by appropriate doses of market samples of unmodified insulin-Lilly of the amorphous type. This preliminary period, during which no comparative studies were carried out, varied from five to sixteen days.

On the first day of the first test period food was withheld, and after samples of control blood and of urine had been secured a dose of the insulin to be tested was given subcutaneously (a carefully selected 0.5 cc. syringe with a scale-bearing portion 4 cm. long and graduated in 0.01 cc. divisions being used) and samples of capillary blood were taken thirty and sixty minutes later and then hourly for from fourteen to sixteen hours. The urine was collected at intervals of two hours and tested for sugar and acetoacetic acid. The quantity of sugar, and in five patients the quantity of nitrogen, was determined in each of the specimens.

At the end of from fourteen to sixteen hours a midnight supper was given, preceded by a suitable dose of insulin. During the next few days, usually four, the patient was maintained on that type of insulin used on the initial test day. Then followed a second test period consisting of (a) an initial day on which food was withheld and a single dose of the second type of insulin under study was given and (b) days of maintenance, usually four, on the same type of insulin. Then the entire procedure was repeated for two more test periods, so that each type of insulin was used during at least two test periods with each patient. This elaboration of the familiar "cross-over" procedure used in animal work helps avoid

TABLE 1.—Results of Assay of Insulin Preparations Used

Type of Insulin	Manu- facturer	<i>pu</i> *	Units per Cc.†	Nitrogen, Mg. per 1,000 Units	Zinc,‡ Mg. per 1,000 Units
Solution of zinc insulin crystals	Lilly,	2.82	40	0.0061	>0.2-0.4
	Stearns	2.90	40	0.0073	0.3- 0.4
Insulin (prepared from amorphous material)..	Lilly,	2.80	40	0.0077	<0.0125
	Stearns	2.74	40	0.0100	0.17-0.21

* The *pu* determinations were carried out by Dr. O. H. Pearson in the department of biochemistry of the Harvard Medical School. They were made electrometrically with a glass electrode.

† Greatest possible difference from 40 is not more than about 5 per cent.

‡ The limits established for the zinc content of "insulin specially prepared as solution of zinc insulin crystals" are not less than 0.2 mg. and not more than 0.4 mg. per thousand units. The content of organic and inorganic impurities is likewise limited.

erroneous conclusions which may be drawn from improvement in carbohydrate tolerance due simply to long continued control of the diabetic condition. It aids also in minimizing the influence of the added care

Chart 10 (case 5).—Response to insulin A (Lilly, solution of zinc insulin crystals) and insulin B (Lilly, amorphous type). Despite the more pronounced effect secured with the crystalline preparation in this patient, as shown in chart 9, the difference in effect on days of maintenance was slight. The blood sugar curves shown here were only slightly lower during the days of maintenance on insulin A (solution of zinc insulin crystals) than on insulin B (amorphous type), and the amount of sugar excreted in twenty-four hours was only slightly less when insulin A was used. The differences both as regards blood and urine sugar determinations are minimal. Again it is worth while to point out that insulin A (crystalline) given before the evening meal was inadequate to prevent fasting blood sugar values of 400 mg. per hundred cubic centimeters, or slightly less, fourteen hours later.

in treatment which both physician and patient often take when trying a new preparation.

The dosage of insulin given on the days of starvation was in four patients 0.15 unit per kilogram of

body weight. In case 2 0.165 unit and in three others (cases 1, 4 and 8) 0.2 unit per kilogram was given. During the days of maintenance insulin was given two, three or four times a day, as indicated by the condition of the patient. Every attempt was made to keep the dosage constant from day to day. Except for the special test days when patients were kept in bed, they

Chart 11 (case 6).—Blood sugar curves following single doses of insulin Stearns (0.15 unit/Kg.). Food was withheld throughout the tests. C₁, crystalline, Jan. 31, 1939; R₂, amorphous, February 6; C₃, crystalline, February 11; R₄, amorphous, February 16; C₅, crystalline, February 21. Miss R. C., aged 20.8 years, had had diabetes since January 1927. The diet during the period of study was carbohydrate 168 Gm., protein 72 Gm., fat 65 Gm. Body weight, 139 pounds (63 Kg.); height, 64 inches (163 cm.). Curve C₁ was quite different from other curves obtained in this patient with the same type of insulin. The other four curves, two showing the effect of the solution of zinc insulin crystals and the other two the effect of insulin of the amorphous type, are remarkably similar, with the two curves following the amorphous preparation lying between the two following the crystalline preparation. One must conclude that, except for curve C₁, there was no essential difference in the response of this patient to the two types of insulin.

were allowed to be up and around. As far as practicable, the amount of physical activity was kept constant from day to day. Five patients (1, 2, 3, 4 and 5) received exclusively insulins made by Eli Lilly & Co. and the three others (6, 7 and 8) those made by Frederick Stearns & Co.

Normal Persons.—For studies on normal persons, eight healthy men (medical students aged from 21 to 24 years) were chosen. The tests on any given student were carried out one week apart. The subjects were asked to keep constant, as far as possible, the time and composition of the evening meal on the day preceding the test day. During the test day the amount of physical activity was minimal; for the most part the subjects lay quietly at rest. Smoking was prohibited. The body temperature was taken as a routine shortly after the beginning of the test. In only two instances was this slightly above normal (99.1 F. in each case), and in only one of these subjects was a cause evident (mild infection of the upper respiratory tract). Since the results of the tests on these days were not unusual, they were included in calculating the general average.

The "cross-over" procedure was employed: on the first test day a single dose of insulin of amorphous (or crystalline) type (0.15 unit per kilogram of body

weight) was given subcutaneously and the response of the blood sugar noted by determinations of capillary samples at half-hourly intervals for the first three hours and then at hourly intervals for the next seven hours. The subjects reported for the tests after an over night fast of twelve hours, and food was withheld during the ten hours of the test day. On the second test day a week later, the other type of insulin was injected. On the third test day, the type of insulin used during the first day was again given and, on the fourth test day, the other type of insulin was administered. Therefore, with each subject four curves were obtained, two with insulin of the amorphous type and two with a solution of zinc insulin crystals. The type of insulin used on the first test day was varied from subject to subject. Four subjects received exclusively insulins made by Eli Lilly & Co. and four others those made by Frederick Stearns & Co.

Rabbits.—No extensive comparison of the insulins made from crystals and those made from amorphous material was carried out in rabbits because (a) Dr. Melville Sahyun¹¹ of Frederick Stearns & Co. had recently reported that average curves obtained when thirty-three rabbits for each type of insulin tested were almost identical and (b) comparisons in large groups of rabbits (from forty-eight to eighty-two animals in a given series of tests), made in the laboratories of the Insulin Committee of the University of Toronto on samples of the same lot numbers sent them by us, showed no significant difference in effect between the amorphous and the crystalline types of insulin. However, we thought it wise to secure some information at first hand and so compared the effect of the four types of insulin, i. e. the amorphous and the crystalline types from the two manufacturers—in each of ten rabbits, using the "cross-over" method. The tests were carried out after a fast of twenty-four hours. Only male rabbits of Dutch breed weighing from 1,500 to 2,140 Gm. were used. Insulin of U-40 strength in dosage of 0.8 unit per kilogram of body weight was injected

Chart 12 (case 6).—Response to insulin C (Stearns, solution of zinc insulin crystals) and insulin R (Stearns, amorphous type). The blood sugar curves during the three day periods of maintenance indicate a slightly greater effect of the crystalline preparation. This is borne out by the smaller amount of sugar in the urine.

subcutaneously, an "Agl" micrometer syringe being used. The capillary blood sugar was determined on samples from the marginal vein of the ear at half-hourly intervals for the first three hours and at hourly intervals for the next three hours. In the six days

between successive tests the animals were maintained on a diet of Park and Pollard rabbit pellets with weekly feedings of lettuce and carrots.

RESULTS

The results of the investigation are presented in the accompanying charts. In charts 1 to 16¹⁸ inclusive the results obtained with the eight diabetic patients are recorded in detail. The charts bearing odd numbers up to and including 15 show the blood sugar curves obtained with a single dose of insulin given subcutaneously on a day of rest and starvation. The values for sugar and nitrogen in the specimens of urine collected at intervals of two hours throughout these tests are not recorded because they add little of importance to the data on blood sugar. The charts bearing even numbers up to and including 16 show the daily blood sugar curves and the daily excretion of sugar and nitrogen in the urine during periods of maintenance on a given type of insulin. In the latter charts the portions that are reproduced are entirely unselected, representing in each instance the data obtained during the last two of the four or more study periods of each patient (except in case 3, in which complete data were not available). The results during the day following that of the special tests were uniformly excluded because the lower values for sugar in the blood and urine, which were then almost invariably obtained, were not consistent with those subsequently shown.

In all the charts, solid lines are used to indicate blood sugar values when solution of zinc insulin crystals was used, and interrupted lines those when insulin made from amorphous material was used. In chart 16 the dotted line shows the effect of protamine zinc insulin.

In chart 17 appear curves which represent composites of those obtained with the eight diabetic patients and shown in the odd numbered charts from 1 to 15 inclusive. The curve labeled "amorphous" represents the average of seventeen curves secured following a single injection of that type of insulin and the curve labeled "crystalline" represents the average of eighteen curves secured following a single injection of solution of zinc insulin crystals. It is obvious from chart 17 that both types of insulin must be considered as rapidly acting with a duration of effect much less than that recognized as characteristic of protamine zinc insulin. The effect of the solution of zinc insulin crystals, however, was definitely, although slightly, prolonged as compared with that of insulin made from amorphous material. In the curve showing the effect of the crystalline type, a slightly greater blood sugar lowering action was evident, and the lowest point occurred one hour later than in the other curve. In the return toward the initial value, a lag of approximately two hours occurred when the solution of zinc insulin crystals was used.

In chart 18 is shown the difference in the duration of effect between insulin of the amorphous type and that of solution of zinc insulin crystals in normal persons. The curves are essentially the same up to three hours after the administration of insulin; the rate of initial fall is the same except in the case of curve B (amorphous type of insulin). After the first three hours curves C and A, showing the effect of two brands of solution of zinc insulin crystals, exhibit a slower return toward normal than do the two curves showing the effect of the amorphous types. The latter

pair of curves reaches a plateau at about six hours, whereas the former pair does so about eight hours after the giving of insulin. However, the differences in terms of actual blood sugar values are slight indeed.

From a study of chart 19, which presents the data secured with rabbits, no significant difference in duration of effect of either type of insulin, amorphous or crystalline, can be claimed. The curves are remarkably alike, considering the fact that the number of animals was small. With all four insulins the initial rate of fall was sharp and the lowest blood sugar level was reached

Chart 15 (case 8).—Blood sugar curves following single doses of insulin, Stearns (0.2 unit/Kg.). Food was withheld throughout the tests. R₁, amorphous, Feb. 11, 1939; C₂, crystalline, February 16; R₂, amorphous, February 21; C₄, crystalline, February 27.

Miss F. H. aged 28.7 years had had diabetes since December 1928. The diet during the period of study was carbohydrate 158 Gm., protein 80 Gm., fat 81 Gm. Body weight, 155 pounds (70.3 Kg.); height, 65½ inches (166 cm.). The rate of fall of the blood sugar was remarkably the same during each test, regardless of the type of insulin used. The solution of zinc insulin crystals exerted a somewhat greater hypoglycemic effect and a slight but definite prolongation of action.

in one and a half hours (with the possible exception in the case of curve A). The return of the blood sugar to normal took place at essentially the same rate in all cases, and at the end of five and six hours the points on the curves produced by the solution of zinc insulin crystals were slightly higher than those on the curves produced by insulin of the amorphous type of the same manufacturer.

COMMENT

It is apparent from the data just presented that the duration of effect of the solution of zinc insulin crystals is fully as great as, and on the whole somewhat greater than, that of insulin made from amorphous material. The prolongation of action is particularly evident in certain of the patients with diabetes. In an attempt to decide more definitely regarding the comparative duration of effect, we have analyzed the curves obtained

¹⁸ To save space, charts 3, 4, 5, 6, 7, 8, 13 and 14 have been omitted. They appear in the authors' reprints.

with the eight diabetic subjects on the special test days during which a single dose of insulin was given and food was withheld. As guides we have arbitrarily chosen two points on each curve: (a) That at which the blood sugar begins the return from the lowest value. This is usually the lowest point itself, except that we have regarded as insignificant a variation of 5 mg., thereby allowing for those instances in which the blood sugar remained at the lowest level for more than one reading. (b) That at which the blood sugar curve in its return to the initial value crosses the 180 mg. abscissa. The number of hours after the injection of insulin required for the curve to reach these points then serves to indicate the length of action of the preparation under study. We attempted also to determine the num-

of seven hours as the time required to leave the lowest point was obtained with sixteen curves following the amorphous type in eight patients, whereas the corresponding average value in eighteen curves following the crystalline type in the same eight patients was 7.8 hours. Furthermore, it will be seen in table 2 that an average of 9.6 hours was required for the blood sugar on its return to the initial value to cross the 180 mg. abscissa; the corresponding value for the crystalline type was 11.2 hours.

From a clinical standpoint, of even more significance than the data just discussed are the results with the eight diabetic patients during the days of maintenance on the two types of insulin, as shown in the even-numbered charts from 2 to 16 inclusive. In the final

analysis, the important consideration is whether, with given doses of one type of insulin, hyperglycemia and glycosuria are less than on the same doses of the other type. Casual inspection of these charts shows that there was very little difference between the degree of control secured with a solution of zinc insulin crystals and that with insulin made from amorphous material. Such slight differences as were apparent were usually on the side of slightly lower values for sugar in blood and urine while the solution of zinc insulin crystals was used. Closer study of these charts together with portions of them not reproduced in this paper leads to this same conclusion. The average number of grams of sugar excreted in the urine by eight patients during sixty-five days of maintenance on insulin of the

Chart 16 (case 8).—Response to insulin C (Stearns, solution of zinc insulin crystals) and insulin R (Stearns, amorphous type). The first two divisions of the chart show the blood sugar curves during three day periods of maintenance, first with the crystalline and then with the amorphous preparation. There was no essential difference; if one judges from the output of sugar in the urine, the degree of control was slightly better with insulin of the amorphous type. The third portion of the chart, in which the blood sugar curve is represented by a dotted line, is appended to illustrate what takes place when a type of insulin is used which truly has a prolonged action. On February 28 the patient was returned to our usual schedule of giving doses of unmodified insulin, amorphous type, plus a dose of protamine zinc insulin in the morning before breakfast (on this day and on March 1 small doses of noon meal and before the evening meal as indicated). In striking contrast the blood sugar values approached normal and the sugar disappeared from the urine. The total dose of insulin given also before the evening meal on March 3 was 60 units, as compared with that of 74 units on February 18 when the solution of zinc insulin crystals was being used.

ber of hours required for the complete return to the initial value, but since this occurred in only a few instances the average figures are not of significance. The average values for the two points just defined are given in table 2.

TABLE 2.—Duration of Effect on Blood Sugar of Insulin Made from Amorphous Material and of Solution of Zinc Insulin Crystals Following a Single Injection

	Time Required to Leave the Lowest Point		Time Required to Cross the 180-Mg. Abscissa	
	Number of Curves	Hours	Number of Curves	Hours
Amorphous	16*	7.0	11	9.6
Crystalline	18	7.8	13	11.2

* One curve (chart 13, curve R2) was omitted because the value of four hours was obviously not representative.

It is evident that the action of the solution of zinc insulin crystals was slightly prolonged as compared with that of insulin of the amorphous type, but the difference was not great. As shown in table 2, the average value

of seven hours as the time required to leave the lowest point was obtained with sixteen curves following the amorphous type in eight patients, whereas the corresponding average value in eighteen curves following the crystalline type in the same eight patients was 7.8 hours. Furthermore, it will be seen in table 2 that an average of 9.6 hours was required for the blood sugar on its return to the initial value to cross the 180 mg. abscissa; the corresponding value for the crystalline type was 11.2 hours.

From a clinical standpoint, of even more significance than the data just discussed are the results with the eight diabetic patients during the days of maintenance on the two types of insulin, as shown in the even-numbered charts from 2 to 16 inclusive. In the final analysis, the important consideration is whether, with given doses of one type of insulin, hyperglycemia and glycosuria are less than on the same doses of the other type. Casual inspection of these charts shows that there was very little difference between the degree of control secured with a solution of zinc insulin crystals and that with insulin made from amorphous material. Such slight differences as were apparent were usually on the side of slightly lower values for sugar in blood and urine while the solution of zinc insulin crystals was used. Closer study of these charts together with portions of them not reproduced in this paper leads to this same conclusion. The average number of grams of sugar excreted in the urine by eight patients during sixty-five days of maintenance on insulin of the amorphous type was 26 Gm., as compared with 18 Gm. by the same patients during sixty-seven days of maintenance on the same dosage of the crystalline type. It must be conceded that the difference between these two figures is slight, in view of the fact that the patients received from 137 to 247 Gm. of carbohydrate a day. Furthermore, the average daily excretion of nitrogen in the urine of five patients while maintained on the amorphous type was 14 Gm., the same as that during maintenance on the crystalline type.

It is worth while to point out again that in our studies of diabetic patients the rate of fall of the blood sugar in the four to six hours following a single dose of insulin was found to be essentially the same for the crystalline and the amorphous types. In other words, the rapidity of action seems essentially the same and, although we have no direct data on this point, there would appear to be no reason why a solution of zinc insulin crystals cannot be used when a quickly acting type is desired, such as in diabetic acidosis and coma. We agree with the suggestion that insulin of the crystalline type might well be made the quickly acting market insulin, supplanting the amorphous type. Theoretically at least it should give rise to fewer allergic

responses than the amorphous type, although at the present time certain market preparations of the latter type are of a high degree of purity. It seems to act slightly longer, and this is a further point of desirability, since no rapidity of action is sacrificed. It cannot, however, be regarded as an insulin with prolonged activity in the sense that protamine insulin, with or without zinc, is. It certainly does not act two or more times as long as the amorphous variety, and in the patient with severe diabetes a dose before the evening meal does not prevent hyperglycemia the following morning before breakfast. In our experience protamine zinc insulin remains the slowly acting, long lasting insulin of choice; in this respect solution of zinc insulin crystals cannot be compared with it.

SUMMARY

1. Detailed studies comparing the rapidity of action and duration of effect of unmodified insulin made from amorphous material and of solution of zinc insulin crystals

Chart 17.—Composite blood sugar curves showing the average response of eight diabetic patients to single subcutaneous doses of insulin of the amorphous type and of "insulin specially prepared as solution of zinc insulin crystals" (composites of curves in the odd numbered charts from 1 to 15 inclusive).

tals were carried out on eight normal persons and on eight patients with severe grades of diabetes of long duration. Comparative tests were also made in a small series of rabbits.

2. Insulin from two manufacturers (Eli Lilly & Co. and Frederick Stearns & Co.) was used. The potency and zinc and nitrogen content of the samples of insulin were verified by determinations made in the laboratories of the Insulin Committee of Toronto.

3. Insulin made from amorphous material and insulin specially prepared as solution of zinc insulin crystals caused a prompt fall, almost identical in rate, of the blood sugar of both normal and diabetic subjects. Both must be regarded as rapidly acting insulins.

4. In normal rabbits the duration of action of insulin "specially prepared as solution of zinc insulin crystals" was almost identical with that of insulin made from amorphous material. In normal human subjects the action of the crystalline type appeared to be slightly prolonged. In diabetic patients a similar prolongation of effect was, in general, apparent. With the diabetic

subjects there occurred on the average a slightly greater blood sugar lowering action following the crystalline type. The lowest point in the curve following a single injection was reached in six hours in the case of the amorphous and in seven hours in that of the crystalline

Chart 18.—The response of the blood sugar of normal persons to insulin following the subcutaneous injection of a single dose of 0.15 unit per kilogram of body weight. Food was withheld throughout the tests. Each curve represents the composite of eight curves, two for each of four persons. A, solution of zinc insulin crystals-Lilly; B, insulin-Lilly, amorphous type; C, solution of zinc insulin crystals-Stearns; R, insulin-Stearns, amorphous type.

variety. In the return to the initial value there was (up to fourteen hours after the injection) a lag of approximately two hours when the crystalline type was used.

Comparison of observations made during days of maintenance on the two types of insulin in similar dosage shows that the values for sugar in the blood and urine were on the average slightly less when a solution of zinc insulin crystals was used. The differences were of such slight degree as to be of minor significance clinically.

5. To simplify treatment for patients and physicians alike, it is advisable to decrease, rather than increase, the number of types of insulin on the market. At the

Chart 19.—The response of the blood sugar of fasting rabbits following a single dose of insulin injected subcutaneously in the amount of 0.8 unit per kilogram of body weight. Each curve represents average values obtained with ten animals. A, solution of zinc insulin crystals-Lilly; B, insulin-Lilly, amorphous type; C, solution of zinc insulin crystals-Stearns; R, insulin-Stearns, amorphous type.

present stage of development, it seems desirable to limit these to (a) a rapidly acting insulin which might well be prepared from crystalline rather than from amorphous material and (b) a slowly acting variety, the protamine zinc insulin.

SOLUTIONS OF AMORPHOUS INSULIN AND SOLUTIONS OF ZINC INSULIN CRYSTALS

CLINICAL STUDIES ON THE COMPARATIVE SPEED
AND DURATION OF ACTION

HENRY T. RICKETTS, M.D.

CHICAGO
AND

RUSSELL M. WILDER, Ph.D., M.D.
ROCHESTER, MINN.

We submit the accompanying blood sugar time data from experiments designed to test the comparative speed and duration of action of solutions of amorphous and crystalline insulin. The data were obtained under the following conditions:

1. The subjects were eight patients with diabetes of different but previously established degrees of severity. The disease was of moderate severity in three cases and severe in five. In all cases it was of two or more years' duration and no patient had been under observation in the hospital for less than eight days immediately preceding any experiment. All but two patients had been under the supervision of one of us for one or more years.

2. For at least four days, and usually for from one to two weeks, before any experiment no insulin containing protamine was administered. a constant diet was

mental day and a single dose of the insulin to be tested was injected subcutaneously in a region of the skin not previously used for subcutaneous injections. The size of the dose was from one third to one half the previous morning dose of insulin. All subsequent tests of the same or of any other insulin on a given individual were made with the same dose. Uniformity of hydration of blood and tissues was sought by administering orally 500 cc. of water five hours before the injection of insulin and 150 cc. at hourly intervals beginning an hour before the injection and ending seventeen hours later. The insulin was injected at 8 a. m. and capillary blood was sampled for reducing power immediately before the injection¹ and at hourly or two hourly intervals thereafter until 8 p. m. or midnight; again in most cases at 2 or 3 a. m., and finally at 8 a. m., twenty-four hours after the injection. No food was given during the entire period.

4. At least two, and usually all, types of insulin employed were tested on each subject so that their effects could be compared in single patients as well as in all patients taken together.

5. The preparations of insulin tested were (a) a commercial solution of amorphous insulin ("iletin," insulin-Lilly); (b) two preparations of insulin from the Eli Lilly Company of composition unknown to us: insulin A and insulin B, one of them reputedly a solution of amorphous insulin and the other a solution of zinc insulin crystals; (c) a commercial preparation of solution of zinc insulin crystals (Stearns).²

fed and either two or three injections were given daily of one of the preparations of insulin under investigation. These injections were administered in such a way as to control glycosuria only incompletely and to insure a high value for the blood sugar each morning. No experiment was undertaken until a reasonably constant degree of postabsorptive hyperglycemia had been established, and an interval of not less than three days elapsed between all experiments on any subject.

3. The individual experiment was performed as follows: The patient was confined to bed on the experi-

From the Department of Medicine of the University of Chicago and the Mayo Clinic and Mayo Foundation.

Owing to lack of space, this article is abbreviated here by the publication of a condensed table instead of the complete tables, which appear in the authors' reprints.

Drs. Natalie Deyrup, Lester Odell and Russell M. Wilder Jr., of the University of Chicago Clinics, and Drs. Kendrick Smith and Sam H. Mann, of the Mayo Clinic, collected numerous samples of capillary blood. Dr. Wright Adams, of the Department of Medicine, and Mr. John Smith, of the School of Business, University of Chicago, gave valuable aid in the statistical analysis of our data.

This investigation was originally supported by a grant from the Eli Lilly Company for the sole purpose of studying the comparative speed and duration of action of their preparation known as "iletin (insulin, Lilly)" and "iletin (insulin, Lilly) specially prepared as Solution of Zinc-Insulin Crystals." As the study proceeded our interest prompted us to subject other preparations of insulin to the same tests. No support was received for any part of the work done in Rochester.

In table 1 is shown the average fall in values for blood sugar after injection of these preparations of insulin, the results being expressed both as milligrams per hundred cubic centimeters and as the percentage of the original level. These data are presented graphically in terms of percentage of decrease in blood sugar

1. The analytic methods for determining the reducing power of the blood were the method of Miller and Van Slyke (*J. Biol. Chem.* 114: 583, 1936) in the experiments performed at the University of Chicago and the Folin ferricyanide method (*J. Biol. Chem.* 77: 421, 1928) in the experiments at Rochester.

2. The package containing insulins A and B was sent to one of us (H. T. R.) by the Eli Lilly Company. It was opened in the presence of Dr. Paul Leech, secretary of the Council on Pharmacy and Chemistry of the American Medical Association. Samples of both insulins were removed by Dr. Leech for analysis (see footnote 4), and of the remaining bottles some were taken to the University of Chicago for clinical trial and some were sent to Rochester for the same purpose. Samples were also sent to Dr. T. G. Klumpp, of the Food and Drug Administration, Department of Agriculture, Washington, D. C. The commercial solution of amorphous (regular) insulin ("iletin," insulin-Lilly) was purchased in the open market and bore the lot number K8-971246-X2. The solution of zinc insulin ("Stearns") also purchased in the open market, bore the lot : of U-40 Lorne Hutchison, secretary of the Insulin Committee of Toronto, reported in a personal communication that on the basis of assays on bulk batches this preparation of "iletin" (insulin-Lilly), contained about 41 units per cubic centimeter and the Stearns product about 40.3 units per cubic centimeter. Further assays made by the Insulin Committee on the actual lot numbers used by us were reported as showing the two insulins to be "very similar in potency."

in chart 1, in which the effect of amorphous insulin ("iletin," insulin-Lilly) is compared with that of solution of zinc insulin crystals (Stearns), and in chart 2, in which is compared the effect of insulin A with that of insulin B.

It is apparent from lines 1 and 2 in table 1 and from chart 1 that there are appreciable differences after 12 o'clock noon between the average percentage of fall

Chart 1.—Percentage of fall in values for blood sugar after injection of solution of amorphous insulin ("iletin," insulin-Lilly) and solution of zinc insulin crystals (Stearns). Each point represents the average of the results in from seven to four patients (lines 1 and 2 in the table). The two insulins were tested on each subject. The points about the curves show an unduly wide scatter because of the fact that from 12 noon to 8 p. m. specimens for blood sugar were taken only every second hour in the three Rochester patients whereas they were taken every hour in the four University of Chicago patients. Specifically, there are no data for the Rochester group for the hours 1, 3, 5, 7, 9 and 10 p. m. and midnight. The individual blood sugar curves were much smoother than these average curves would indicate.

in values for blood sugar after injection of solution of zinc insulin crystals (Stearns) and the average percentage of fall in such values after injection of amorphous insulin ("iletin," insulin-Lilly). These differences, however, are not sufficiently large to render it certain that they are real or important. The mean difference for each hour, therefore, was calculated from the original data and the resulting data were analyzed by statistical methods.³ The analysis shows that for the hours 1, 2, 3 and 4 p. m. the differences observed possess statistical significance ($P < 0.05$). The average of the mean differences for each individual also proved to be significant.

There was, on the other hand, no significant difference between the values for insulin A and those for insulin B (lines 3 and 4 in table 1 and chart 2).

Our interpretation of the results of these experiments is influenced by the following considerations:

Although our procedure was designed to insure uniformity of experimental conditions, it must be recognized that the physiologic status of any diabetic patient probably varies from one day to another. Thus, although we aimed at having the postabsorptive value for the blood sugar at the beginning of each experiment on any one subject the same, we were not always successful in accomplishing this. It is for this reason that it has been necessary to express our results in terms of decrease in values for blood sugar from the fasting level in each experiment rather than in terms of absolute values for blood sugar. Again, it is evident from the

data of individual patients that when the same insulin was tested twice on the same subject the results, while comparable, were never identical. This fact renders it probable that any differences which might be observed under the conditions of our experiments would need to be relatively large to be important clinically. Finally, we realized early in the course of this study that repeated days of starvation, even though separated by periods of several days during which the subject's usual diet was fed, might lead to progressive improvement in the patient's diabetes so that his response to insulin might differ in the first experiment as compared with the last. Some evidence of such an effect was observed in a few of the milder cases but it was not apparent in most. In an effort to avoid this difficulty, the order in which the various insulin preparations were tested was changed from patient to patient.

In spite of these difficulties, the experimental procedure we have employed involves fewer variables than tests of insulin action made when patients are receiving food or when they are ambulatory and physical activity is not controlled. We believe, therefore, that our results justify the following comments:

The most conspicuous feature of the blood sugar time curves which may be constructed from our data is the relative constancy of the rate of decline of the values for blood sugar during the first three hours of each experiment. This we interpret as indicating that the speed of activity of solutions of zinc insulin crystals is as great as that of solutions of amorphous insulin.

In certain individual experiments the blood sugar remained at a low level longer after injection of a solution of zinc insulin crystals (Stearns) than after injection of preparations of amorphous insulins, although this result was obtained inconstantly. Also the averaged data of the experiments in which this product was used would appear to show a slight but statistically significant increase in duration of effect. The prolonga-

Chart 2.—Percentage of fall in values for blood sugar after injection of insulin A and insulin B. Each point represents the average of the results in from six to five patients (lines 3 and 4 in the table). The two insulins were tested on each subject.

tion of action, however, is not marked and its importance in the ordinary treatment of diabetes mellitus is yet to be ascertained.

Our figures give no indication of any definite difference of speed or duration of action between the two "unknown" products sent to us by the Eli Lilly Company. After the experiments were completed we were

3. Fisher, R. A.: Statistical Methods for Research Workers. Edinburgh, Oliver & Boyd, 1934.

informed by the Eli Lilly Company that insulin A was a solution of zinc insulin crystals and "insulin B" was a solution of amorphous (regular) insulin.⁴

CONCLUSIONS

Blood sugar time data obtained after the injection of single doses of insulin given without food to diabetic patients in the postabsorptive state failed to disclose material differences in speed or duration of action between solutions of amorphous (regular) insulin and solutions of zinc insulin crystals supplied by the Eli Lilly Company. The average of all data obtained by the injection of solution of zinc insulin crystals (Stearns) shows a slight but statistically significant prolongation of action, though no difference in speed of action, when compared with the average of all data obtained after injection of amorphous insulin. This difference was not apparent in all patients, and it does not seem likely that a prolonged effect of such small degree, obtained inconsistently, can represent a difference of clinical importance.

LANDMARKS IN SIMPLE PLEURAL EFFUSIONS

JULIUS KAUNITZ, M.D.

NEW YORK

Modern methods of examination have greatly facilitated the diagnosis of pleural effusion, particularly radiography. In spite of this it is nothing unusual for experienced clinicians to be embarrassed by a "dry tap" when there is clearcut evidence of pleural effusion. Nor is the embarrassment lessened when a successful thoracentesis is performed on the patient on the same day by another clinician who elected to introduce his needle one or two interspaces higher.

In most instances "dry taps" in simple effusions are due to the eagerness of the operator to remove every ounce. The patient is placed in the sitting position regardless of his physical condition, and the needle is introduced at a low level, frequently so low that it encounters diaphragm instead of liquid. One of the chief reasons for failure in thoracentesis is that the landmarks of the effusion are not clearly established. This is particularly true of the more common type, the simple pleural effusion, which is to be distinguished from hydropneumothorax and from cases in which tumor and adhesions complicate and distort the picture.

Before the advent of the x-rays many clinicians described the upper level of effusions as curved or straight, depending entirely on the upper margin of the flat percussion note. Probably one of the earliest descriptions is the curved line of Damoiseau¹ mentioned in most of the foreign textbooks. In this country we are taught the curved line of Ellis.² As shall be shown,

neither of these lines truly represents the upper level of the effusion.

The ordinary roentgenographic appearance of simple pleural effusions is exemplified in figure 1 A. Here is seen a dense shadow at the base of the right lung field. The top of this shadow curves upward and outward from the hilus to the sixth rib in the axilla. By introducing air into the pleural space the simple effusion or hydrothorax becomes converted into hydropneumothorax (fig. 1 B). It is noted that the upper level is now a straight horizontal line. The explanation for this phenomenon has been considered in a previous article.³ The horizontal line noted in hydropneumothorax describes accurately the upper level of the effusion. On percussion from above downward there is an abrupt change from hyperresonance to flatness. In simple effusions, however, both radiographic and physical signs are not quite so distinct. The percussion note changes from normal to dullness and flatness. It is extremely difficult accurately to locate the upper level of the effusion; this difficulty also applies to the roentgenogram.

It was not until a radiopaque oil was employed that it was possible to locate the upper level of the effusion. This experiment is illustrated in figure 2. Following the removal of 10 cc. of the pleural effusion an equal volume of a combination of iodized poppyseed oil and cajuput oil was replaced. The oil immediately floated to the top, as seen in figure 2 B, its highest point being on the same level with the outer tip of the curved dense shadow and definitely above the hazy shadow. The same result was obtained also in the anterior and posterior oblique views. It would appear from these observations as well as from our clinical knowledge that in simple pleural effusions the lung is surrounded by liquid.

Fig. 1.—A, characteristic simple pleural effusion. Note the dense radiographic shadow curving concavely upward from the hilus to the axilla and the hazy shadow immediately above. B, same case after injection of air into the pleural space. Note the straight horizontal line and the absence of the hazy shadow.

The effusion may be compared with an irregularly shaped bowl in the hollow of which is the lung and surrounding which are the chest wall, mediastinal structures and diaphragm. The radiographic shadow cast by the bowl appears very dense at the bottom and sides and least dense in the hollow where aerated lung is interposed.

For the sake of convenience I have divided simple pleural effusions into three radiographic zones,⁴ as follows, described from below upward:

1. A radiopaque zone, the area below the lung, visualized as a dense shadow.

3. Kaunitz, Julius: Liquid Levels and Other Liquid Surfaces in Pleural Effusions, *J. Thoracic Surg.* 4: 300 (Feb.) 1935.
4. Kaunitz, Julius: The Three Zones of Simple Pleural Effusions, *Am. J. Roentgenol.* 35: 57 (Jan.) 1936; The Three Radiographic Zones of Simple Pleural Effusions, *Brit. J. Radiol.* 9: 644 (Oct.) 1936.

4. This information was confirmed by Dr. E. W. Schoeffel of the chemical laboratory of the American Medical Association, who reported as follows: "Insulin A, reaction generally exhibited by Eli Lilly's new solution behaves similarly in solution. Insulin B in solution but does differ in several respects from available product. In conclusion, it can be said that insulin A approaches crystalline zinc insulin in solution. Insulin B approaches ordinary insulin plus a small surplus of unidentified matter." The batch represented by insulin A and the batch represented by insulin B were supplied for our clinical experiments because of the fact that, according to assays of these two batches by the manufacturer and in the laboratories of the Insulin Committee of the University of Toronto, insulin A and "insulin B" would be of essentially identical strength, any slight difference of this from a strength of 40 units per cubic centimeter being approximately the same for the two insulins.

2. Ellis, Calvin: *Boston M. & S. J.* 90: 13, 1874.

2. A radiotranslucent zone, the area between the lung and chest wall, seen as a hazy shadow but dense in the lateral aspect.

3. A radiotransparent zone, the area of liquid between the lung and chest wall too thin to cast a shadow except in its lateral aspect.

The volume of liquid at the various levels of the second and third zones is easily gaged by observing the curved dense shadow as it tapers off from below upward.

Fig. 2.—*A*, simple pleural effusion, as in figure 1 *A*. *B*, same case immediately after 10 cc. of effusion was replaced by an equal volume of radiopaque oil. Note the ascension of the oil into the clear field above the hazy shadow. The effusion is divided into three radiographic zones (for explanation see text).

This curved shadow is in fact a side view of that portion of the effusion interposed between the lung and chest wall, the tip of the curved shadow representing the upper margin of the effusion.

With the three zones as a landmark it is possible with a greater degree of accuracy to choose the site for thoracentesis. In effusions of moderate size it has been my custom to insert the aspirating needle at a point corresponding to the junction of zones 1 and 2 in the posterior axillary line. This corresponds to the beginning of absolute flatness in percussion. Aspirating below this point may be successful with large effusions; in small effusions the diaphragm may be encountered and may not be recognized, particularly on the right side where the flat percussion note over the liver merges with that over the effusion and the dense homogeneous x-ray shadow includes diaphragm, liver and effusion.

When feebleness of the patient precludes aspiration in the erect position, the reclining position may advantageously be employed. The usual procedure in right-sided effusions is to place the patient on his right side at the edge of the right side of the bed, and vice versa in left-sided effusions. The needle is inserted in an interspace near the posterior axillary line. In this position the liquid will gravitate downward from between the lung, mediastinum and diaphragm and permit almost complete aspiration.

Although the liquid is not as freely movable in simple pleural effusion as in hydropneumothorax, it does how-

ever change its position with the chest. These changes have been thoroughly described by Rigler.⁵

It is of interest to note that small effusions may entirely be hidden in the ordinary postero-anterior roentgenogram. In figure 3 *A*, taken in the erect position, a slight clouding in the right costophrenic sinus is seen. This small shadow suggests that a minute amount of effusion is present, "a teaspoonful" as many would describe it. When I injected 300 cc. of saline solution in a chest of normal adult size I was not able to obtain any shadow in the costophrenic sinus. Emerson and Ganter, as mentioned by Rigler, were unable to obtain radiographic evidence of effusion in the presence of 250 cc. and 450 cc. respectively. The liquid is probably concealed by the liver and diaphragm in the posterior costophrenic sinus. A shadow in the lateral costophrenic sinus is therefore indicative of the presence of at least 250 cc. of effusion in a normal sized chest. By changing the position of the patient it is possible to visualize some of the liquid concealed by the liver and diaphragm. Figure 3 *B* (same case as figure 3 *A*) was taken in the right decubitus position, and here a considerably greater amount of effusion may be visu-

Fig. 3.—*A*, erect position, a small pleural effusion is suspected because of the slight clouding in the right costophrenic sinus. *B*, same case; right decubitus position; note the ribbon-like shadow extending along the lateral lower border of the right lung.

alized appearing as a ribbon-like shadow along the right border of the lung. This small effusion might easily be aspirated in this position for diagnostic purposes.

CONCLUSIONS

It is important to know the landmarks of a pleural effusion before attempting thoracentesis.

5. Rigler, Leo G.: Roentgen Diagnosis of Small Pleural Effusions: A New Roentgenographic Position, *J. A. M. A.* 96:104 (Jan. 10) 1931.

By special roentgenographic technic it was established that the simple pleural effusion extends well above the area of percussion flatness and above the dense radiographic shadow.

On the basis of distinct radiographic zones in simple pleural effusions, several principles have been formulated for locating with greater accuracy the site for thoracentesis.

THE TREATMENT OF PNEUMOCOCCIC PNEUMONIA WITH CONCENTRATED RABBIT SERUM

ITALO F. VOLINI, M.D.

AND

ROBERT O. LEVITT, M.D.

CHICAGO

There have been few reports submitted concerning the use of rabbit serum in the type specific therapy of pneumonia. This is particularly true of the concentrated and refined serum. The steadily increasing improvements in the character of the serum have indicated the fulfilment of the factors defining a good serum for therapy; namely, first that the intravenous administration be without undue reaction and second that the adequate dose be contained in a small volume. The theoretical and practical advantages that antipneumococcus rabbit serum possesses over horse serum have been pointed out by several observers.¹ These observations, however, have been made with the unconcentrated rabbit serum. Finland and Brown² describe the use of the concentrated serum in sixteen cases with two deaths in type I pneumonia. The present report deals with the administration of concentrated and refined rabbit serum in 153 patients, comprising twenty-one different types of pneumococcic infection.

CASE SELECTION FOR SERUM

The principal criterion for the selection of cases suitable for serum therapy was the availability of serum. Owing to the large number of pneumonia patients, the serum supply was generally inadequate. Consequently control comparisons were easy to obtain, practically of an alternate case character. These control data are found in table 2. Serum was not refused even when the outlook was very bad, such as the presence of pulmonary edema or duration of the disease of five or six days, factors which elevate death rate percentages. A positive Francis test or an otherwise good prognosis was frequently utilized to conserve our serum supply for the more necessary or urgent indications. Unquestionably the mortality percentage is thus higher in our series than it would be if a more rigid selection had been employed.

From the Cook County Hospital and the Department of Medicine, Loyola University School of Medicine.

The Pneumonia Committee of the Cook County Hospital and the attending physicians and resident staff cooperated with the authors in this work. The serum used was supplied by the Lederle Laboratories, Inc., the Illinois State Department of Public Health and E. R. Squibb & Sons.

METHODS OF STUDY

Typing was accomplished by the Neufeld method, applied directly to the sputum. Blood cultures were taken as a routine. Lung puncture, sputum culture and mouse inoculation were employed when difficulties with direct sputum identification were encountered. Repetition of the bacteriologic investigation was performed when the improvement expected did not result, in order to detect possible mistakes in the initial typing.

The intracutaneous test with specific polysaccharide was carried out after serum had been used whenever possible in those cases in which a negative Francis reaction had been present before serum was given.

SENSITIVITY TESTS AND UNTOWARD REACTIONS

The history of possible sensitivity was thoroughly investigated. The ophthalmic test for sensitization was employed as a routine. A positive test was not encountered in the entire series. The intracutaneous testing for rabbit serum sensitivity was discarded early in the investigation because of the frequency of positive read-

ings, especially since we found that the administration of serum in these cases did not result in immediate reactions. No positive intravenous pressor reactions occurred. Difficulty was encountered especially in evaluating pulse rate changes during the course of the pressor test. The significance of this procedure is considered doubtful. We have not encountered an immediate reaction in the entire series.

Thermal reactions were studied carefully because of their great frequency in the early phases of this study. This corroborates the observations of other investigators using rabbit serum. While the inherent thermogenic properties of the serum are very important, the controllable factors in this type of reaction are numerous. The rapid administration or dilution of the serum was found to be the important feature in producing chill and elevation of temperature. There was very little constancy or relationship to the particular injection in the divided dose method. This led us to try the single total undiluted dose method. The advantages of this procedure are obvious. The concentrated refined rabbit serum lends itself admirably to this technic, especially in the highly

concentrated unitage. It soon became apparent that the serum could be given at a more rapid rate without danger. The procedure now is to administer the first cubic centimeter in a period of two minutes, then the entire remainder at a rate of 1 cc. a minute. If the

at the indicated rate. One is cautioned to aspirate a minimal amount of blood into the syringe to indicate the intravenous position of the needle. The last sixty-nine consecutive patients in this series were treated by the single total undiluted dose technic with an incidence

of only 8 per cent of thermic reactions compared to 28 per cent in our preceding eighty-four cases. With the highly concentrated unitage, this method requires only from ten to twenty minutes. A maximum of 35 cc. as the initial and total dose was given in this way without thermic reaction. A unitage concentration of 5,000 per cubic centimeter or over is particularly adaptable. We have tested the practicability of this method by having twelve interns inject sixty-nine patients. We believe that the therapeutic efficiency of the serum is enhanced by this method of administration.

Serum sickness (delayed reactions), such as arthralgia, urticaria and fever, occurred in 28 per cent of the cases. There was no relationship between the thermic reactions and the frequency of serum sickness.

CLINICAL RESULTS

This statistical study from the Cook County Hospital of a series of 153 patients with pneumococcic pneumonia treated by type specific antibody rabbit serum demonstrates a death rate less than one third, almost one fourth, that of the non-serum treated mortality. The

figures in tables 1 and 2 illustrate this rather vividly. Of the fifteen deaths that resulted, four occurred within eighteen hours after the administration of serum. If these deaths are removed from the statistics the death rate would be lowered to 7 per cent. The control series approximates very closely the serum treated figures in the several important variables, namely age, type of pneumococcic infection, bacteremia and seasonal incidence. There were thirty positive blood cultures in the control cases and twenty-three in the serum treated cases.

Table 3 shows thirty-three serum treated patients over 50 years of age with three deaths. These include eight type III cases with two deaths and nine type II pneumonias with one death.

A study of the temperature curves following serum administration in the patients who recovered shows a descent to normal within eighteen hours, a crisis termination, in seventy-seven patients. Normal temperature readings appeared in a forty-eight hour period in sixty-one cases.

An analysis of the deaths reveals the following important data: Fifteen deaths occurred. Four of these were

of bacteremic patients. Four occurred within eighteen hours after admission. No autopsies were permitted on these four. Autopsy showed in two patients suppurative pericarditis and in the remaining patient an acute pneumococcic endocarditis type VII. Deaths were restricted to types I, II, III, IV, VII, VIII, XIV (table 1).

COMPLICATIONS

This series shows relatively few complications. This tends to confirm the observations that there is probably an advantage in the penetrating and diffusing properties due to the smaller size of the rabbit serum pneumococcus antibody. Empyema occurred in five patients, all of whom recovered. Two patients with pericarditis and one with acute endocarditis died. One patient with acute suppurative otitis media complicated by meningitis with type IV pneumococcus obtained from the spinal fluid recovered. There were two other cases of otitis media, one showing extension to the mastoid. The usual supportive and symptomatic measures were utilized in the general treatment. Digitalis was not employed. Intravenous fluids and oxygen were liberally administered. The need for these measures was distinctly less-

The unitage presented as described on the manufacturer's label.

ened in the serum treated patients, owing to the frequent abrupt recovery shortly after the use of the serum. The serum treated patients did not receive sulfanilamide or sulfapyridine. The latter drugs were employed for some patients of the control series.

SUMMARY AND CONCLUSIONS

Concentrated and refined antipneumococcus rabbit serum is an efficient therapeutic agent in the type specific treatment of lobar pneumonia. This controlled study demonstrates the mortality rate of the non-serum treated patients four times that of the rabbit serum series. Sensitivity to the therapeutic rabbit serum is rarely encountered. It is remarkably free from immediate reactions and produces a relatively small percentage of thermal and delayed serum reactions. It lends itself to the concentrated single total dose administration, which procedure saves much time and probably enhances its therapeutic efficiency.

Cook County Hospital.

RENAL COMPLICATION IN SULFAPYRIDINE THERAPY

REPORT OF FIVE CASES WITH ONE DEATH

Y. F. TSAO, M.D.
MARY E. McCRACKEN, M.D.
JI CHEN, M.D.
P. T. KUO, M.D.
AND
C. L. DALE, M.D.
SHANGHAI, CHINA

In view of the rapidly increasing popularity in the use of sulfapyridine by the medical profession, it seems wise to report in detail five cases of hematuria, some of which were complicated with abdominal pain resembling that of renal or ureteral origin and one of which was complicated with uremia and was fatal. A special report by the Council on Pharmacy and Chemistry of the American Medical Association,¹ based on reports received from about 100 investigators, mentioned toxic renal manifestations of sulfapyridine as very rare cases in which there is temporary hematuria, which in some cases has been quite severe. In the same issue of THE JOURNAL three cases of hematuria, one presenting visible blood, occurring in association with the administration of sulfapyridine were reported by Southworth and Cooke² of New York. In two of their cases there were severe abdominal pain of renal and ureteral origin and nitrogen retention in the blood. Antopol and Robinson³ reported formation of uroliths in the urinary tract of rats, rabbits and monkeys fed with sulfapyridine. Gross, Cooper and Lewis⁴ produced urinary calculi containing 6.4 per cent sulfapyridine and 64.1 per cent acetylsulfapyridine in twenty-seven of thirty-nine rats by the administration of 1 Gm. of sulfapyridine per kilogram of body weight by mouth in two weeks or less. They also found that these urinary calculi caused death in some and varying degrees of renal damage in other animals by complete or partial urinary obstruction, with associated hematuria, pyelonephritis and nonprotein nitrogen, as well as retention of sulfapyridine. We are in accord with Southworth and Cooke that, as far as we can determine, there is no report of cases of renal complication in human beings other than the three they have reported and the four cases of gross hematuria, usually accompanied by ureteral pain, mentioned in a report of fifty cases of pneumococcic pneumonia by Graham,⁵ nor have we seen any report of a death due to such renal complication.

REPORT OF CASES

CASE 1.—M. N. W., a girl aged 6 years, weighing 29 pounds (13 Kg.), was admitted April 3, 1939, with the chief complaint on admission of fever and cough of three days' duration. There was no history of former urinary disease. Routine

From the departments of urology and pediatrics of the American Hospital for Refugees, and the departments of pathology and biochemistry, Pennsylvania Medical School of St. John's University.
All the sulfapyridine used in our hospital was prepared by Société Parisienne d'Expansion Chimique.
The chemical formula given is $C_{10}H_{10}N_4O_2$.

examination of the urine showed a specific gravity of 1.021, a slight trace of albumin, pus cells 1 plus (about 5 to 10 per high power field), no erythrocytes, no casts and an alkaline reaction. Physical examination revealed coarse mucoid rales over both bases with diminished breath sounds and dullness over the left base posteriorly. Next morning there were more signs of localization of the lesion over the left lower lobe of the lung. Sulfapyridine was then started with 1 Gm. orally at 10 a. m. and 0.5 Gm. every four hours. The fever, which was around 102 to 104 F. after admission, dropped to normal within twenty-two hours after the treatment was begun and the lung signs began to clear. April 5 there was some vomiting and anorexia; sodium bicarbonate was given. April 6 at 6 a. m. (about forty-four hours after the initial dose of sulfapyridine) she passed grossly bloody urine. Gross hematuria was also present at 11 a. m. and 7 p. m. Urinalysis showed specific gravity 1.015, albumin 3 plus, no casts, few leukocytes (about 2 to 5 per high power field) and 4 plus erythrocytes. Coagulation time was 7.5 minutes and bleeding time was 1.5 minutes. A total of 7 Gm. of sulfapyridine had been given and was stopped immediately on detection of the hematuria. Fluid was forced and sodium bicarbonate was continued. The next day the urine specimen showed an alkaline reaction, a specific gravity of 1.015, no casts, no erythrocytes and leukocytes 1 plus. On the following day the urine was also essentially normal and no erythrocytes were found; the child was discharged April 10 without any sign of renal damage. A chemical analysis of the blood was not done.

CASE 2.—T. C. Y., a boy aged 7 years, weighing 30 pounds (13.6 Kg.), was admitted April 17, 1939, with the chief complaint of cough for three months and marked dyspnea for two weeks. Physical examination showed marked dyspnea and cyanosis, very dirty carious teeth and coarse and fine mucoid rales all over the chest. Clinical diagnosis was bronchopneumonia following pertussis. Routine urine examination showed a specific gravity of 1.026, alkaline reaction, no casts, no albumin, no erythrocytes and a few leukocytes. Pneumococcus type VI was isolated from the sputum. Sulfapyridine was started immediately with 1 Gm. followed by 0.5 Gm. every four hours for twenty-two doses, making a total dosage of 12 Gm. in about four days; 0.5 Gm. of sodium bicarbonate was given with each dose of sulfapyridine. Other medication included 7,000 international units of vitamin B and 16,000 international units of vitamin C during six days. On the evening of the 19th after about 7.5 Gm. of sulfapyridine (about fifty-four hours after the initial dose) blood was noted macroscopically in the urine, but this was not reported until two days later when there was already apparent improvement in redness of the urine, which had shown erythrocytes 4 plus the day before. The drug was immediately stopped after this report was received. One day after the sulfapyridine was stopped there was marked general improvement with return of appetite. April 24 the urine showed a specific gravity of 1.004, no albumin, no casts, only a few leukocytes and no erythrocytes. Improvement continued and the patient was discharged eighteen days later without any symptoms or signs of urinary trouble.

CASE 3.—C. A. S., a boy aged 8 years, weighing 40 pounds (18 Kg.), was admitted May 13, 1939, from a children's refugee camp with no history available. His chief complaint was anorexia of long duration. The temperature on admission was only 99 F. Physical examination was essentially negative. A locally prepared vitamin B solution and a dose of castor oil were given after admission while we were waiting for further observation. The temperature rose to 104.6 F. at 8 a. m. the next day; owing to congestion of the pharynx, sulfanilamide 0.18 Gm. three times a day was begun and given for one day. The specimen of urine taken while the patient was on sulfanilamide therapy revealed slight cloudiness, an acid reaction, a specific gravity of 1.020, few leukocytes, 4 mg. of ascorbic acid per hundred cubic centimeters of urine and no casts or erythrocytes. Examination of the blood revealed a leukocyte count of 5,500 with a differential count of 45.5 per cent of neutrophils, 48 per cent lymphocytes and 6.5 per cent monocytes. On the following day, because of detection of numerous mucoid rales in the base of the right lung, sulfapyridine was used instead

of sulfanilamide. About forty-eight hours after the initial dose of the sulfapyridine and a total of from 6 to 6.5 Gm. of this drug having been given, slightly blood-tinged urine was noticed by the attending nurse, who, however, did not feel it important enough to inform the attending physician, since the dosage of the sulfapyridine had already been reduced. Next morning, after a total of 7.25 Gm. of sulfapyridine had been given, the patient passed about 150 cc. of markedly bloody urine, which on examination showed a specific gravity of 1.005, acid reaction to litmus paper, albumin 3 plus, leukocytes 1 plus, erythrocytes 4 plus and numerous unidentified crystals, which were described as long and slender and grouped mostly in bundles resembling uric acid or leucine crystals but not typical of either. Another 0.5 Gm. of sulfapyridine was allowed, though the fever had already returned to normal. After the 150 cc. of bloody urine, and during the entire next week until his death, he did not pass more than 80 cc. of urine. May 19, about ninety hours after the initial dose of sulfapyridine, the first convulsion occurred; another attack occurred during the night and another at 5 a. m. on the 20th. The blood pressure on that date was 122 systolic, 92 diastolic. With this picture acute glomerular nephritis after bronchopneumonia or chemical nephrosis was suspected. It was considered that this might be due to the administration of sulfapyridine, though no report of any such action of this drug has come to our attention. Very slight results as far as the urinary output and general condition were concerned were obtained with the often repeated intravenous dextrose therapy, and repeated dosage of 50 per cent magnesium sulfate, both orally and by retention enemas. Decapsulation of both kidneys was considered but not performed, because of the poor condition and risk of the patient. The patient complained of some abdominal pain but he did not make this clear after the occurrence of convulsions. Signs of congestion of the lungs were detected on the 23d, and the general condition of the patient rapidly declined. Chemical analysis of the blood showed nonprotein nitrogen 165 mg. and urea nitrogen 75 mg. per hundred cubic centimeters. The patient died of uremia and terminal bronchopneumonia on the 25th.

AUTOPSY PROTOCOL SUMMARY⁶

The body was well developed and moderately well nourished. The cranial vault was normal. The middle ears and mastoids presented only a small amount of mucoid secretion. The tympanic membranes were intact. There were no enlargements of the lymph nodes in the neck. The throat structures were normal. The thyroid was of normal gross appearance. The chest presented both pleural spaces clear and free of adhesions. The right lung revealed an apical peripheral lesion characteristic of a moderately advanced primary Ghon tuberculous infection. The rest of the lung revealed a moderate diffuse bronchopneumonia. The left lung presented a similar degree of bronchopneumonia but there was no tuberculous involvement. The hilar lymph nodes were enlarged, chiefly on the right, and revealed a moderate amount of caseation necrosis. The heart was of fairly good tone with mild right-sided dilatation, and the valves were normal. The peritoneum was clear. The mesenteric lymph nodes were somewhat enlarged and some presented caseation necrosis, especially those nearest the ileocecal area. The gastrointestinal tract presented tuberculous ulceration of the terminal ileum involving the ileocecal valvular ring. The spleen was slightly enlarged and of a moderate gray soft character. The liver was somewhat enlarged and of a dull mottled appearance on cut section. Microscopic section revealed peripheral small droplet fatty metamorphosis with moderate central congestion. The adrenals were congested and microscopically showed medullary hyperplasia of moderate degree.

The urinary system presented both kidneys slightly enlarged. Both capsules stripped readily, leaving smooth surfaces. The cortices were thickened and the cut surface showed moderate congestion. The pelves were slightly dilated and the pelvic mucosae were somewhat thickened, congested and hemorrhagic. Both ureters were dilated to a diameter of 8 mm. to the distal cystic portion. The mucosae of the ureters were likewise thickened, congested and hemorrhagic. The bladder was small

6. By Dr. C. L. Dale.

and contracted and contained a small amount of gray sandy particles. The right ureteral orifice protruded into the bladder in the form of a congested hemorrhagic papilla which would not admit a small probe either from the cystic side or from a slit made in the distal part of the ureter. There were a few small concretions in this part of the ureter of about 2 mm., grossly resembling "uric acid sand." The left ureteral opening did not project as a papilla but was moderately congested. A probe would not enter from the cystic side. On probing from a slit in the distal ureter a mass of concretion was found to plug the orifice effectually and only after its removal did the probe pass through. Unfortunately this sandlike material was lost in the fluids and was not examined for sulfapyridine. Microscopic sections of the kidney revealed marked tubular dilatation both of the convoluted and of the collecting tubules. The glomeruli were enlarged and presented a compression of the capillary tufts, which appeared small and dark with a wide clear space between the tuft and Bowman's capsule. There was very little cellular reaction in the glomerular tufts. There were areas of marked congestion and hemorrhage in the medullary portions. Section of the pelves and ureters revealed marked congestion, edema and some hemorrhage, with a small amount of leukocytic infiltration, chiefly lymphocytes.

The cause of death was attributed to bronchopneumonia with uremia due to anuria caused by bilateral ureteral obstruction of the orifice.

CASE 4.—M. M. W., a girl aged 11 years, weighing 30 pounds, was readmitted May 27, 1939, after spending sixteen days in the isolation hospital with measles. For three days in our hospital her temperature fluctuated between 101 and 103 F., and bilateral myringotomy was done on May 29. Routine urinalysis showed slight cloudiness, alkaline reaction, albumin 2 plus, leukocytes 1 plus, no casts and no erythrocytes, and ascorbic acid 0.8 mg. per hundred cubic centimeters of urine. May 31 we decided to try sulfapyridine with an initial dose of 1 Gm. followed by 0.5 Gm. every four hours. The first was given at noon and the second dose at 4 p. m. The patient vomited and complained of some abdominal pain after the second dose. On the following morning she passed grossly bloody urine, which on examination showed an alkaline reaction, a specific gravity of 1.012, albumin 4 plus, erythrocytes 4 plus and no casts. Sulfapyridine was immediately stopped, a total of only 3.5 Gm. of the drug having been given. Sodium bicarbonate 0.3 Gm. every four hours was then given. The patient complained of severe abdominal pain and marked tenderness in the costovertebral angle on both sides. Her temperature dropped to normal during the night and rose to 99.6 F. the next morning. She vomited four times during that day and had definite oliguria. Fluids were forced and the gross hematuria gradually disappeared on the following day. Examination of the blood showed coagulation time 4.5 minutes, bleeding time 1 minute, platelet count 275,000 and fragility test with an initial hemolysis at 0.44 per cent and the complete hemolysis at 0.30 per cent, nonprotein nitrogen 31 mg. per hundred cubic centimeters, urea nitrogen 16 mg., uric acid 3.3 mg., creatinine 1.2 mg., chloride 460 mg. and calcium 12.1 mg. The next two days the alkali reserve of the blood was 70 mg. and 68.2 mg. per hundred cubic centimeters respectively. *Streptococcus haemolyticus* was isolated from the discharging ears. Sulfapyridine was given again after the patient showed no microscopic hematuria and had no more complaint of abdominal pain and tenderness. A total of 2.5 Gm. of sulfapyridine was given during the next twenty-four hours, but no hematuria was observed either macroscopically or microscopically. Sulfapyridine was then stopped but the temperature rose again to 102.6 F. and sulfapyridine was resumed with a total dosage of 3.25 Gm. spaced in forty-eight hours. Examinations of the urine were negative for the first forty-eight hours but showed erythrocytes 1 plus on the third day. Sulfanilamide was then substituted for sulfapyridine.

CASE 5.—M. M. Y., a girl aged 17 months, weighing 16 pounds (7.3 Kg.), was admitted May 24, 1939, with a history of diarrhea, cough and fever for two weeks following measles and marked dyspnea for the last two days. The clinical diagnosis was bronchopneumonia. Sulfapyridine was immediately started with 1 Gm. for the initial dose and 0.25 Gm. every

four hours for sixteen doses and 0.125 Gm. every four hours for eighteen doses. May 30, sulfapyridine was stopped and chemical analysis of the blood showed nonprotein nitrogen 36 mg. per hundred cubic centimeters, uric acid 4.3 mg. and creatinine 1.2 mg. May 31, examination of the urine showed a few erythrocytes, a few leukocytes, an alkaline reaction and a trace of albumin, but the next specimen of urine was negative for erythrocytes. Two days after this sulfapyridine was again given for two days, intended for the patient's bilateral otitis media and an abscess; the specimen of urine taken right after sulfapyridine was stopped showed an acid reaction and 1 plus for erythrocytes.

COMMENT

We have treated a series of about forty patients with sulfapyridine in our pediatric department. The cause for such a high incidence of renal complication has not been determined; it is interesting, however, to note that most of our patients are suffering from general nutritional deficiency, dehydration and polyvitaminosis in addition to their chief complaint.⁷ Whether or not this is sufficient to explain the frequent renal complication is not certain.

That hematuria may occur as early as within twenty hours after the initial dose of sulfapyridine (case 4) is remarkable. In three cases the hematuria occurred after forty-eight hours (cases 1, 2 and 3). Only in case 5 was it delayed for six days. Dosage does not seem to be an important factor in these cases. Ours was based on the age and is lower than that recommended by Barnett, Hartmann, Perley and Ruhoff;⁸ in three cases it was 50 per cent higher than that (calculated on the basis of the patient's weight) recommended by Wilson and his colleagues,⁹ in one case it corresponded to theirs and in the fatal case it was lower than theirs.

The autopsy definitely showed complete bilateral obstruction of the urinary tract by uroliths—the obstruction was in the terminal cystic portion of both ureters, and the patient died of uremia as the consequence of the complete obstruction. There were definite signs of recent acute dilatation of the upper urinary tract and petechial hemorrhages along the ureter and the renal pelves. We are induced to think that the hematuria in this case was the result of direct trauma on the urinary structures by the spiculated calculi and the backward pressure from the obstruction. Had we had this knowledge and suspicion when the patient began to suffer anuria and tried cystoscopic manipulation of the ureters or even emergency nephrostomy, the life of this patient might very well have been saved.

Our cases do not agree with the report on experimental animals by Gross and Cooper that the sulfapyridine calculi were associated with acid urine. Our cases showed that renal hematuria can occur in connection with both alkaline and acid urine in human beings. Sodium bicarbonate was given with the sulfapyridine in cases 1, 2 and 4, and the urine in these cases was alkaline. In case 5 hematuria occurred first with alkaline urine and recurred with acid urine on repetition of sulfapyridine therapy. In most of our cases in the pediatric department sodium bicarbonate was usually given with sulfapyridine; there occurred these five cases of renal hematuria with one death. On

7. This hospital admits only sick refugee Chinese, many of whom are living under very difficult circumstances such as are seldom if ever seen in the United States.

8. Barnett, H. L.; Hartmann, A. F.; Perley, Anne M., and Ruhoff, Mary B.: *The Treatment of Pneumococcal Infections in Infants and Children with Sulfapyridine*, J. A. M. A. **112**: 518 (Feb. 11) 1939.

9. Wilson, A. T.; Spreen, A. H.; Cooper, M. L.; Stevenson, F. E.; Cullen, G. E., and Mitchell, A. G.: *Sulfapyridine in the Treatment of Pneumonia in Infancy and Childhood*, J. A. M. A. **112**: 1435 (April 15) 1939.

the other hand, in the medical department of our hospital, where forty cases of adults were treated with sulfapyridine without sodium bicarbonate, there was not a single case of renal complication in the form of hematuria or any sign of urolithiasis. This suggests that children are more liable to renal complications with sulfapyridine medication; therefore, while this drug is administered, they should be very carefully watched and frequent examinations of the urine should be made for erythrocytes and sulfapyridine and acetylsulfapyridine crystals or stone formation.

SUMMARY

1. Five cases of hematuria were associated with administration of sulfapyridine in children.

2. One of these patients died of uremia as a result of bilateral complete urinary obstruction, proved at autopsy.

3. Hematuria may occur within twenty hours but may be delayed as long as six days after the initial dose of sulfapyridine.

4. The real mechanism of formation of the hematuria is still not known, but it may be associated with formation of uroliths.

5. Cystoscopic examination and ureteral manipulation and even emergency nephrostomy or renal pyelotomy with probing of the ureter for possible urinary obstruction by a competent urologist should be made when signs of marked urinary obstruction and anuria develop during the administration of sulfapyridine.

6. Children are probably more susceptible to renal complication in sulfapyridine medication and more care should be taken during its administration in pediatric cases.

Clinical Notes, Suggestions and New Instruments

A CASE OF WEIL'S DISEASE

WALTER HASCHEC, M.D., AND FRANKLIN J. TOBEY, M.D.
House Physician and Chief of Medical Service, Respectively,
St. Mary's Hospital
ORANGE, N. J.

A condition characterized by sudden onset, prostration, fever, jaundice, muscular pains, hemorrhagic tendencies and renal involvement was first described by Weil¹ in 1886. In 1914 Inada was able to transmit this disease to guinea pigs by inoculating them with blood taken from patients suffering from this disease. The following year he² discovered that a spirochete was the etiologic agent. Noguchi³ found that this organism differed from other spirochetes in that it did not have a terminal filament and that it was resistant to 10 per cent saponin and termed it *Leptospira icterohaemorrhagiae*.

Since 1922 about twenty-two cases of this disease have been reported in this country. We believe that our case is the first to be reported from New Jersey. Many authorities believe that this apparent rarity of the disease in the United States is due to failure to diagnose it rather than to scarcity of the disease. It is interesting to note that jaundice was a prominent feature in twenty-one out of twenty-two cases reported in America, although investigators in foreign countries find that about 50 per cent of their patients lack jaundice. One should therefore include Weil's disease in the differential diagnosis

even when jaundice is absent but other symptoms are suggestive and call on the laboratory to confirm or reject one's suspicions. The following laboratory methods enable us to make a positive diagnosis of Weil's disease: guinea pig inoculation, darkfield examination, agglutination tests and tissue and smear staining.

Since Wolbach and Binger's⁴ discovery in 1914, it has been known that natural waters of various kinds contain organisms which morphologically are similar to those which cause Weil's disease. However, these organisms are nonpathogenic and have been named *Leptospira biflexa*. There are several pathogenic strains of organism which morphologically resemble *Leptospira icterohaemorrhagiae* and cause such diseases as (a) swamp fever of eastern Europe, (b) akiyami or seven day fever of Japan and (c) a disease in dogs which resembles Weil's disease.

Weil's disease has been found throughout the world in locations where rats are present. Approximately 10 per cent of the rats in the world are infested with *Leptospira icterohaemorrhagiae*. Mice also frequently act as carriers. These animals carry the organisms in the tubules of the kidney, excreting them in the urine and thus inoculating water, soil or food with which they come in contact. Jorge⁵ reports an epidemic in Lisbon in 1931 in which *Leptospira* was found in a public fountain. It was discovered that this water was contaminated by rat feces.

There are several ports of entry of the organisms into the body. The disease has followed cuts and needle pricks.⁶ Infection by mouth has been produced experimentally and the Lisbon epidemic is an example of it. The disease was accidentally caused by spraying the infected material into the eyes of two laboratory workers.⁷

The period of incubation ranges between four and twenty days, usually from eight to twelve.

The principal pathologic changes in this disease are confined chiefly to capillaries, kidneys, liver and skeletal muscles together with generalized jaundice.⁸

Injury to capillaries is evidenced by the generalized hemorrhages in various tissues: subserous, mucosal, skin and brain, as well as parenchyma of liver, spleen, pancreas and the like. Capillary damage is sometimes very severe and is responsible for the epistaxis, hematemesis, hemoptysis and purpura. It is believed that the capillaries are damaged by the toxic action of the spirochetes.

Grossly the liver appears jaundiced and slightly enlarged. Microscopically the most common pathologic changes are hyperplasia of the liver cells, stasis in biliary capillaries toward the center of the lobule and some infiltration of portal spaces by leukocytes and lymphocytes.

The kidneys are usually slightly enlarged and jaundiced. Microscopically the most common pathologic changes are swelling and necrosis of the epithelium of convoluted tubules, and some infiltration of interstitial tubules by lymphocytes and to a lesser extent by leukocytes.

Very commonly calf muscles and less often other skeletal muscles present small hemorrhages and small areas of degeneration, which are infiltrated by several types of wandering cells.

Inada⁹ recognized the fact that the clinical and pathologic features of the disease divided it into three stages: febrile, toxic and convalescent.

The First or Febrile Stage.—The disease usually begins with a chill, high fever and prostration. The more common symptoms are gastrointestinal disturbances, abdominal pain, conjunctivitis, herpes labialis, severe muscular pains and signs of

meningeal irritation. Examination of the blood shows a leukocyte count of between 10,000 and 20,000 and numerous spirochetes, but antibodies are lacking. Some degree of azotemia is present but the organisms cannot be found in the urine. This stage lasts from five to seven days.

The Second or Toxic Stage.—In about 50 per cent of the cases jaundice appears, and many cases show hemorrhagic tendencies. The liver is usually enlarged but the spleen is usually not palpable. Most of the symptoms of the first stage decrease in intensity and the temperature slowly falls to normal. Azotemia usually increases and there may be oliguria and even anuria. During this stage antibodies appear, spirochetes disappear from the blood and many organisms are excreted in the urine. This stage lasts from seven to ten days. When death occurs it is usually in this stage.

The Third or Convalescent Stage.—This stage is characterized by subsidence of the previous symptoms. In severe cases there is marked emaciation and anemia. In about one third of the cases there is another appearance of a low grade fever, which usually lasts from one to two weeks. Inada felt that this fever was due to disintegrating toxins caused by high serologic immunity. During this stage the organisms completely disappear from the blood stream and are excreted in the urine in large numbers. The serologic immunity is at its height during this stage.

REPORT OF CASE

G. W., a schoolboy aged 17, white, lives in a wooden shack with his mother and brother in Livingston, N. J. The patient's neighborhood is infested with rats—his home in particular. For several months preceding his illness he was in the habit of setting rat traps and removing the animals from the traps. He states that he was never bitten by any of the rats.

Except for the usual childhood diseases, the boy was in excellent health until Aug. 26, 1938. Late in the evening of that day he had a general malaise but nothing very definite. The following morning he was severely prostrated with severe headache, photophobia, congestion of the nose, sore throat, anorexia, nausea, stiffness and severe myalgic pains in the extremities, chilly sensations and fever, which soon rose to 104 F. That day he was seen by a local physician, who made a diagnosis of "grip" and treated the patient in the usual manner, including 10 grains (0.65 Gm.) of sulfanilamide. For the next several days these symptoms continued and the temperature ran high (from 104 to 105 F.). The physician saw the patient again on the morning of August 31. At that time he noted that, besides the stiffness and painfulness of the extremities, the neck was stiff and Kernig's sign was positive. The room was darkened because of the patient's photophobia, making it impossible to see whether the patient was jaundiced. That day the boy was sent to St. Mary's Hospital in Orange, N. J., with the admitting diagnosis of meningitis.

On admission the patient presented a picture of severe prostration and deep jaundice. He wore dark spectacles because of the photophobia. He was conscious and oriented but mentally sluggish. He vomited almost continuously. The vomitus was scanty and blood stained. He objected to being moved in bed because of the pain which was produced in his extremities. His chief complaints were generalized pains, severe frontal headache, nausea and vomiting, photophobia and distress in the upper half of the abdomen. He stated that he had not urinated or defecated in the past four days.

More detailed examination showed the temperature 101.4, pulse rate 104, respiratory rate 24, blood pressure 110 systolic, 60 diastolic. His scleras were deeply jaundiced and there were extensive subconjunctival hemorrhages. The nasal mucosa was moderately congested. The lips were dry and the tongue had a heavy gray blood tinged coat. The pharynx was congested. The gums were a dark blue and spongy and bled slightly from the margins of the teeth. The breath was foul.

No adenopathy was found in the neck, which was, however, stiff and painful when the head was raised. The lungs were clear except for an occasional coarse rale. The heart percussed

out within the normal boundaries, and its sounds were of fair quality. The abdomen was slightly distended and spastic throughout, especially in the right upper quadrant, where it was also quite tender. The patient complained that the abdomen felt "tight." The liver and spleen were not palpable. Distention of the bladder was not felt.

The extremities were generally stiff and tender and very painful on motion, pains being felt chiefly in the muscular regions, especially the calves. The reflexes were hyperactive. Kernig's sign was positive. Several hemorrhagic areas were found beneath the nails of the fingers.

The patient was unable to void, so that it was necessary to catheterize him to obtain a specimen of urine. About 100 cc. of dark, foul smelling urine was obtained. It showed 1+ albumin, a specific gravity of 1.020, sugar +—, several leukocytes per high power field, no casts and 4+ bile.

The blood count showed 7,900 leukocytes, 3,440,000 red cells and a 65 per cent hemoglobin content (Sahli).

The patient was given a low enema, which was productive of a small amount of tarry fecal material and a few small blood clots.

A lumbar puncture revealed the cerebrospinal fluid to be under increased pressure, but the cell count showed only three lymphocytes per cubic millimeter.

Two days after admission the chemical analysis of the blood showed sugar 125 mg., urea 90 mg., uric acid 10 mg. and creatinine 4.5 mg. per hundred cubic centimeters. The blood gave negative reaction to the Widal test. The Wassermann reaction of the blood was negative. The icterus index was 110. The van den Bergh reaction was positive, immediate and direct. The fragility test showed a slight decrease in the resistance of the red cells to hypotonic saline solution.

During the first few days in the hospital he was given intravenously a good amount of dextrose in saline solution. On his second day he received 500 cc. of citrated blood.

During the first week in the hospital his general condition was practically unchanged. The icterus index rose to 130 on the seventh hospital day. He lost considerable blood from frequent epistaxes. The temperature gradually reached normal after several days. The urine was very scanty and stained deeply with bile. Blood culture showed no growth. On the fourth hospital day a tender liver edge was felt two fingerbreadths and the spleen three fingerbreadths below the costal margin. His vomiting gradually decreased. The vomitus occasionally contained some dark bloody material. The stools were scanty, infrequent, tarry and occasionally mixed with some blood clots. He was given 300 cc. of citrated blood September 6. The following day his trunk and extremities were covered with a macular rash, which disappeared on pressure. This rash gradually grew scantier and finally receded after three days.

He appeared to be somewhat improved during the second hospital week. The icterus index descended to 75. He passed more urine, but the blood urea, uric acid and creatinine values remained unchanged. The photophobia and subconjunctival hemorrhages were still present. The pain and stiffness in the extremities were considerably decreased. The liver and spleen edges were barely palpable. The nausea and vomiting were practically gone and the patient was placed on a high carbohydrate liquid diet. Liver extract and iron were given intramuscularly daily, beginning the fourth day.

Several cubic centimeters of centrifuged urine was injected into a guinea pig subcutaneously and intraperitoneally on September 6. The pig died September 14.

Beginning with the eleventh hospital day and continuing for four days the patient's temperature was between 100 and 101 F. The blood count showed 18,200 leukocytes per cubic millimeter with 89 per cent polymorphonuclears.

During the third hospital week the patient's condition was definitely improved. The icterus index came down to 50. His eyes were clearing up and the photophobia was practically gone. The nausea and vomiting had disappeared and his appetite was slowly returning. He was given another 500 cc. of citrated

blood, and the liver and iron therapy was continued. Several hours before his last blood transfusion, a rash similar to the one described appeared and was accompanied by a moderate itching sensation. It disappeared gradually over a period of four days.

Chemical analysis of the blood September 21 showed urea 48 mg., uric acid 6.5 mg. and creatinine 3.7 mg. per hundred cubic centimeters. At this time his blood showed a hemoglobin content of 53 per cent, 2,930,000 erythrocytes and 11,850 leukocytes.

The fourth and fifth hospital weeks saw the patient's gradual recovery. The icterus index reached 28 September 27 and chemistry of the blood revealed urea 21 mg., uric acid 3 mg., and creatinine 1.5 mg. per hundred cubic centimeters. The jaundice in the scleras was very light and the subconjunctival hemorrhages had cleared. The stool was brown and the urine was only faintly bile stained. He was taking a soft diet very well. He regained sufficient strength to sit up in a chair and walk gently about his room. The hair on his head appeared very scanty and he had lost about 25 pounds (11.3 Kg.) during the illness. He was discharged from the hospital October 11.

On the seventh hospital day 60 cc. of catheterized urine was centrifuged and 4 cc. of the sediment urine was injected subcutaneously and intraperitoneally into a guinea pig. This pig died eight days later. The autopsy, performed by Dr. E. J. Tiffany at Long Island College of Medicine, revealed marked icterus of the scleras and subcutaneous tissues, subcutaneous and subperitoneal petechial hemorrhages, "butterfly-wing" mottling of the lungs, congestion of the kidneys and liver and a dark hemorrhagic appearance of the adrenals. These conditions are all characteristic of the reaction, in the guinea pig, to infection with *Leptospira icterohaemorrhagiae*. Morphologically typical leptospiras were found by darkfield examination in the pleural fluid, and in the liver and kidney pulp.

Dr. Tiffany injected organisms from this guinea pig into a second guinea pig. This pig had a temperature around 101 to 102 F. daily and finally 104 on the seventh day, when the pig appeared very ill. On this day he was killed. The autopsy showed conditions similar to those found in the first pig. Darkfield examination revealed the same organisms. The organisms from both guinea pigs were grown successfully on artificial culture mediums.

Stock cultures of *Leptospira icterohaemorrhagiae* were agglutinated by the patient's serum taken on the tenth day of the disease in a dilution of 1:320. Serum taken on the thirty-first day of the disease produced agglutination in a dilution of 1:20,000. Most of this laboratory work was done at Long Island College of Medicine.

Some of the patient's blood serum collected on the fifteenth day of the disease was sent to the U. S. Public Health Service at Washington, D. C. We received a reply that the serum from our patient agglutinated with their strain of *Leptospira icterohaemorrhagiae* in the high dilution of over 1:30,000. The reaction was prompt and clear cut and was, therefore, diagnostic for Weil's disease.

Workers from many parts of the world have reported successful results obtained by treating this disease with specific serum.¹⁰ Animal and convalescent serums have been employed with almost equal success. Administration of serum produces an amelioration of the symptoms, a shortening of the duration of the disease and a marked decrease in the mortality rate. In this country the treatment is still symptomatic. The cases are so rare that it has been found impracticable to use the serum.

Inada¹¹ was able to produce marked reduction in the incidence of the disease in a certain Japanese locality by employing active immunization by means of vaccination. Vaccination is, however, impracticable in this country because of the low incidence of the disease.

BACILLARY DYSENTERY

A PRELIMINARY REPORT STRESSING THE BLOOD PICTURE

H. M. GINSBURG, M.D.; EDWARD M. HIRSCHBERG, M.D.,
AND FLORENCE BRISKER, FRESNO, CALIF.

Dysentery, an acute intestinal infection, was known and described during the time of Hippocrates. From 1898 until 1916 various workers isolated organisms which bear their names and are said to be causative agents of bacillary dysentery. The etiology, pathology, symptomatology and treatment of bacillary dysentery have been adequately described and all writers apparently agree on the details.

In Fresno County an outbreak of dysentery is not uncommon each summer. The community is devoted primarily to farming and the migrant farmhands are numerous. They live in any type of shelter and the food that the family secures is not adequate or balanced. The unripe fruit is partaken of freely. The incidence of dysentery is more prevalent in children.

During the summer of 1937 we had occasion to admit to the General Hospital of Fresno County thirty-nine patients suffering from bacillary dysentery. Our attention was particularly attracted to these cases because of the similarity that existed in the reported blood counts. The admitting officer would not hesitate to diagnose dysentery of the bacillary type merely by viewing the blood count.

In nineteen, or 49 per cent, of the thirty-nine cases, culture of the stool was positive, in ten, or 25.5 per cent, it was negative and in ten a culture was not taken. There were twenty-three boys and sixteen girls. The ages of the patients varied from 3 months to 8 years, with an average of 2 years. The length of time that the diarrhea was present on admission varied from one to fourteen days, with an average of 4.4 days. The Flexner bacillus was the most common organism in the positive cultures. The average length of diarrhea was 14.2 days. The average length of the elevated temperature was thirteen days. There were ten deaths, or a 25.5 per cent mortality.

Routine blood counts were taken on admission and subsequent counts were taken as the patient's condition progressed while in the hospital. The white blood counts varied. Some patients had a normal count, others a high normal and the remaining an elevated count up to a maximum of about 30,000. The polymorphonuclear total was not significant but for the major part was elevated. The interesting fact to us was that all cases showed a Schilling differential count with a 95 to 100 per cent shift to the left. This was true in thirty-seven of the thirty-nine cases. Of the other two patients, one was a baby 3 months old and the diagnosis was not substantiated by all the pediatricians. The second case was of fourteen days' duration when first seen. Repeated counts on all patients showed that as the course of the disease progressed and as the temperature and diarrhea abated the Schilling count began showing the shift back to the right. This therefore may account for the second case not showing a 100 per cent shift, since the disease was abating when the patient was admitted. In cases of dysentery due to *Endamoeba histolytica* the white blood cell count is usually normal and no young forms are found in the differential smear. This finding was noted in all cases in which the laboratory reported a culture positive for *histolytica*. These cases of the bacillary type which showed a low white count in spite of the elevated polymorphonuclear cell count always showed an increased white cell count as the process progressed and as the Schilling count showed the shift back to the right.

The records for 1939 to date reveal twenty-one cases of dysentery, of which nineteen are due to the Flexner or the Sonne bacillus and two to *Endamoeba histolytica*. The Schilling count in the nineteen cases showed a shift to the left varying from 95 to 100 per cent. This count, as in those cases of 1937, shifts back to the right as the disease progresses. The two cases due to *histolytica* showed a normal Schilling distribution.

From the General Hospital of Fresno County.

The cases for 1939 will be studied further and at some future date a more comprehensive report will be made covering this subject.

CONCLUSIONS

1. We have attempted to present what we consider an interesting blood condition in cases of bacillary dysentery. We feel that it is possible to diagnose a case of dysentery as of the bacillary type if the Schilling count shows a 95 to 100 per cent shift to the left, except in those cases of long duration.

2. A further complete report will be made as soon as the 1939 cases can be fully studied. It is hoped that by that time other institutions in which dysentery is prevalent will be able to report on this condition.

Special Clinical Article

THE TREATMENT OF INSOMNIA

CLINICAL LECTURE AT ST. LOUIS SESSION

LOUIS J. KARNOSH, M.D.

CLEVELAND

Insomnia is a chronic inability to sleep. To the clinical mind the term connotes a condition in which an alleged sleeplessness is the main or solitary symptom, in which there are few tangible physical causes and in which the pathologic basis, if any, is not readily detectable. A person who has genuine pain and whose physical derangements are such that sleep is obviously impossible is not ordinarily regarded as having insomnia.

What constitutes true insomnia is largely a matter of capricious opinion on the part of both patient and physician. It would be of considerable advantage to determine whether there is a definite optimum of human sleep, that is, a basic requirement comparable to basal metabolism, from which deviations could be measured. Adult normal sleep defies standardization, for even the most regular of sleep rhythms must be regarded as a complex process which can be influenced by both physical and psychogenic excitations.

Basic sleep, if it exists, may be determined best by observing the spontaneous behavior in sleep of persons who live in a neutral atmosphere (if this is ever possible), whose routine is simple, who have little work to do and who are free from serious psychic impacts. In order to learn what constitutes an average sleep rhythm and to recognize what incidental factors modify such normal sleep, fifty women who had recovered from minor psychoses and who did not complain of insomnia were observed for three months in a psychiatric hospital. The optimum period of sleep varied from six and one-half to eight hours. No particular sleep curve was characteristic of any one patient. Age, temperament, menstruation, ovulation (determined by the so-called ovulation drop) and even diet were the endogenous factors correlated with the sleep curve. None of these consistently influenced the number of hours of sleep required. Perhaps the older patients showed a tendency to a little more sleep than the younger subjects and were prone to retire earlier and to get up earlier. Temperament may also have something to do with average sleep requirements, but the observations in this respect

were indecisive. Possibly phlegmatic people require more sleep than those of a livelier and more labile disposition. Menstruation and ovulation made little or no impress on the sleep curve.

On the other hand, excitement incidental to visits by relatives, alterations with other patients or with attendants, and holidays, with their concomitant emotions, were definitely instrumental in breaking the normal sleep rhythm.

From these studies it is inferred that in the absence of grave organic disease the normal sleep rhythm is more vulnerable to psychic impacts than it is to the minor endogenous influences which are frequently credited with causing insomnia. Insomnia is *prima facie* a constitutional disorder in which psychopathologic phenomena play the leading part, although in some instances physical disorders can be revealed as contributing factors.

The person with insomnia often believes that persistent loss of sleep is a calamitous disturbance—a foreboding of death or insanity. Investigations which look into the effects of prolonged sleeplessness by no means tend to support such fears. Although complete deprivation of sleep in young experimental animals, as shown by Kleitman,¹ may prove lethal because of anemia, loss of weight and a collapse of the respiratory and temperature-regulating centers, no such baneful effects have been noted in the human being.

Kleitman² deprived himself of sleep for more than 100 consecutive hours. No anemia developed; neither was there a startling loss of weight. All bodily functions remained normal, and the ability to perform simple mental tests showed no change. Only steadiness in standing was much impaired. In other studies the same benign results were noted, except that some of the subjects experienced a marked, but temporary, ocular imbalance. Furthermore, what few stigmas appeared were readily abolished by a single period of sleep which was not greatly prolonged.

There is no good evidence that insomnia is a *bête noire* which saps one's vitality and health. It is doubtful whether, in the absence of grave physical signs, insomnia *per se* ever caused death. Gillespie³ stated that he has yet to see a patient whose mental disorder could be fairly attributed to insomnia.

Reassurance of the patient is an important part of the treatment of insomnia, no matter what elements contribute to the disorder. The fact that insomnia, however extreme, has never been shown to be a dominant factor in the production of mental illness should be imparted to every person who suffers with sleep disorders. To some patients the possibilities are so dire that they dread bringing up the subject of impending insanity lest their worst fears be confirmed. Whether the patient introduces the subject or not, an open discussion and a proper assuagement may prevent a superimposed anxiety and contribute greatly to the abatement of the insomnia itself.

The person with insomnia frequently complains that his sleep is shallow and so fitful that it is not appreciated as sleep and that he arises in the morning unfreshed, torpid and slow to acquire the mental acuity necessary for his day's work. The depth of sleep is

Read in the Medical Division of the General Scientific Meetings at the Ninetieth Annual Session of the American Medical Association, St. Louis, May 16, 1939.

a matter of no little importance in any discussion of insomnia. It can be measured by the amount of stimulus required to awaken the sleeper. A popular method of studying the depth of sleep has been to record the movements of the patient, the assumption being that the fewer the movements the deeper the sleep. The actogram of Guttman,⁴ the hypnograph of Schiele⁵ and the recording camera of Johnson and his associates⁶ are all devices to obtain such data. In applying them in the case of insomnia, various results have been obtained as to the structure and quality of sleep. Important is the fairly consistent observation that the patient's own estimate as to the amount of sleep he enjoys is less than that obtained from the nurses' observations and decidedly less than that recorded by the mechanical device.

Since there is good reason to believe that most persons with insomnia exaggerate the degree of their sleeplessness, the physician should be aware of this propensity to overpaint the picture and should not be guided by the subjective data in his therapeutic approach. Shallow, fitful sleep may not be satisfactory but is often a natural condition compatible with the temperament and living habits of the individual patient and does not necessarily call for special attention or treatment.

Insomnia's favorite attack is on the very early hours of sleep, the "temps latent" of Ladame,⁷ which is the time between retiring and of actually going to sleep. During this interval even the normal person experiences a certain twilight state. With the muscles gradually relaxing and the eyes closed, various imaginal mechanisms come into consciousness. They consist of a panorama of loosely connected and untranneled ideas which may, among other things, contain a review of the day's events and plans for the morrow, gradually giving way to disjointed fantasies, which are fragments of experiences both remote and recent. Characteristic of this fantasmagoria is the absence of a dominating concept or theme; there seems to be no ability to hold to one particular fantasm and to reject others. Willy-nilly the thoughts pass in and out of consciousness without cohesion or regulation. Such loose linkage of ideas is called free association, and psychopathologists look on this mental rambling as an overture to sleep, in fact a half sleep wherein the higher cerebral functions which regulate logical and coherent thinking are at rest.

The person with insomnia dreads this phase of his sleep troubles. The period of free association torments him, for it may last several hours. He attains the portals of sleep but seems to have trouble getting any further. Moreover, the panorama is generally fearful and morbid, and its contents, although disconnected, frequently disclose the general source of anxiety. One of the immediate causes of insomnia is an anxious preoccupation, such as great concern over health, the repercussion of bitter family scenes, reflection on sexual inadequacy or infidelity, contemplation of business reverses and various other frustrations of

the ego. These elements come and go despite the desire to forget them. As a matter of fact, the person with insomnia tries to forget them and in so doing makes matters worse, for he merely represses them and the effort keeps him from sleeping.

The sufferer may resort to such devices as counting sheep, reading in bed and other mental gymnastics that require concerted thinking. These are merely tricks for the further repression of unpleasant ideas and therefore actually lead the patient away from, rather than toward, sleep. The person with insomnia should be told to lie down, to let his muscles relax if he can, to let his thoughts wander where they will and to avoid the exercise of any sort of concentration or volition. No one can will himself to sleep; one merely allows sleep to intervene. He should be informed with regard to the phenomena of free association. If free association is a morbid and anxious experience, it is so because the patient has problems which should be cleared up in his waking hours. He must not use them as bedfellows.

Muscular relaxation is an essential precondition of sleep and was particularly emphasized by Kleitman. In the nervous person with insomnia, this is often as difficult to attain as is sleep itself. The only radical method for inducing bodily relaxation is the relief of the anxiety, but there are useful adjuvants. A good bed and a quiet room are obviously important. The bath is useful in reducing muscle tone but is not uniformly helpful. From fifteen to twenty minutes in a tub of water which is just cool to the touch is recommended if it does not upset the patient. Hot baths and massage are of questionable value.

Many sleepless patients resist the temptation to take an afternoon nap because they fear that they will not sleep so readily at night. There is no foundation for this fear. On the contrary, a moderate amount of diurnal sleep is beneficial; it teaches relaxation and engenders confidence in the person with insomnia for it demonstrates that he is capable of genuine sleep.

Nearly one half of all persons with chronic insomnia belong in the psychoneurotic category. The psychoneurotic patient emphasizes his need of sleep because sleep offers him a respite from his psychic conflicts. He not only wants sleep—he wants oblivion. He entertains the naive hope that after a night's good rest he may awake free from tension and depression and that the medication will wash away the problems which he is unable to face and solve. The psychoneurotic patient artfully presents his insomnia as a red herring across the path of the clinician's speculations to mislead him into believing that the trouble is a somatic one which merits medical treatment.

It is clear that the first and only satisfactory method of treating sleeplessness in the psychoneurotic states is to remove the source of psychologic tension. A mental aeration is far more valuable than a sedative. Sedatives should be regarded only as an adjunct, not as a device to cover up the fundamental difficulty. Only agents which act speedily and act intensely for a sufficient time to cover up the period of anxious preoccupation and to initiate sleep are indicated. The newer barbiturates, which are rapidly disintegrated, are particularly useful. One full therapeutic dose should be given at bedtime. The patient should not be preoccupied with the promise of additional doses if the first one fails, and morbid

curiosity as to the kind of sedative given should be discouraged. The dose should be gradually reduced without the knowledge of or despite the remonstrations of the patient. Habituation is more likely to occur in the psychoneurotic patient because of his innate instability.

A large number of patients with a history of head injury become inveterate in their insomnia. Sleepless-

treatment should be mainly that which is applicable to the psychoneurotic person.

The patient with a manic-depressive psychosis is a poor sleeper only if he is agitated. Early morning awakening may be pathognomonic of the depressive phase, and it is obvious that the hypnotics which possess a prolonged action may be administered to advantage. These should be given in adequate doses and may even

be administered to the extent that continuous narcosis is produced.

An extremely trying ordeal is the nocturnal excitement and sleeplessness of the manic phase, particularly in the younger person. The use of the continuous tub and prolonged narcosis have both proved to be unsatisfactory not only because of the irregular results but because of the danger of vasomotor collapse. Paradoxically, the most efficient agent is the metrazol convulsion. The administration of metrazol so modifies the behavior of the manic patient that after three or four convulsions the mood often returns to normal and concomitantly normal sleep is reestablished (chart 1). Eight manic patients and one depressed patient with insomnia and agitation were treated in this fashion with gratifying results. Moreover, in six other cases of depression and in one case of mania in which insomnia was not present the use of this convulsing drug did not interfere with the normal sleep cycle. Although one must give grave consideration to the recent disconcerting reports of Polatin, Friedman, Harris and Horwitz⁸ to the effect that the metrazol convulsion frequently causes compression fractures of the vertebrae as well as dislocations, it appears that no other mea-

sure can quell the excitement of the manic phase or the agitation of the patient with melancholia in the same effective manner as this admittedly radical technic.

Almost as difficult to control as the insomnia of the manic phase is the excitement of the young schizophrenic patient, although in schizophrenia sleep is not consistently disturbed. Sedatives have a very unsatisfactory and irregular influence, particularly on catatonic excitement. The insulin shock technic yields better and more lasting results. Although during the course of

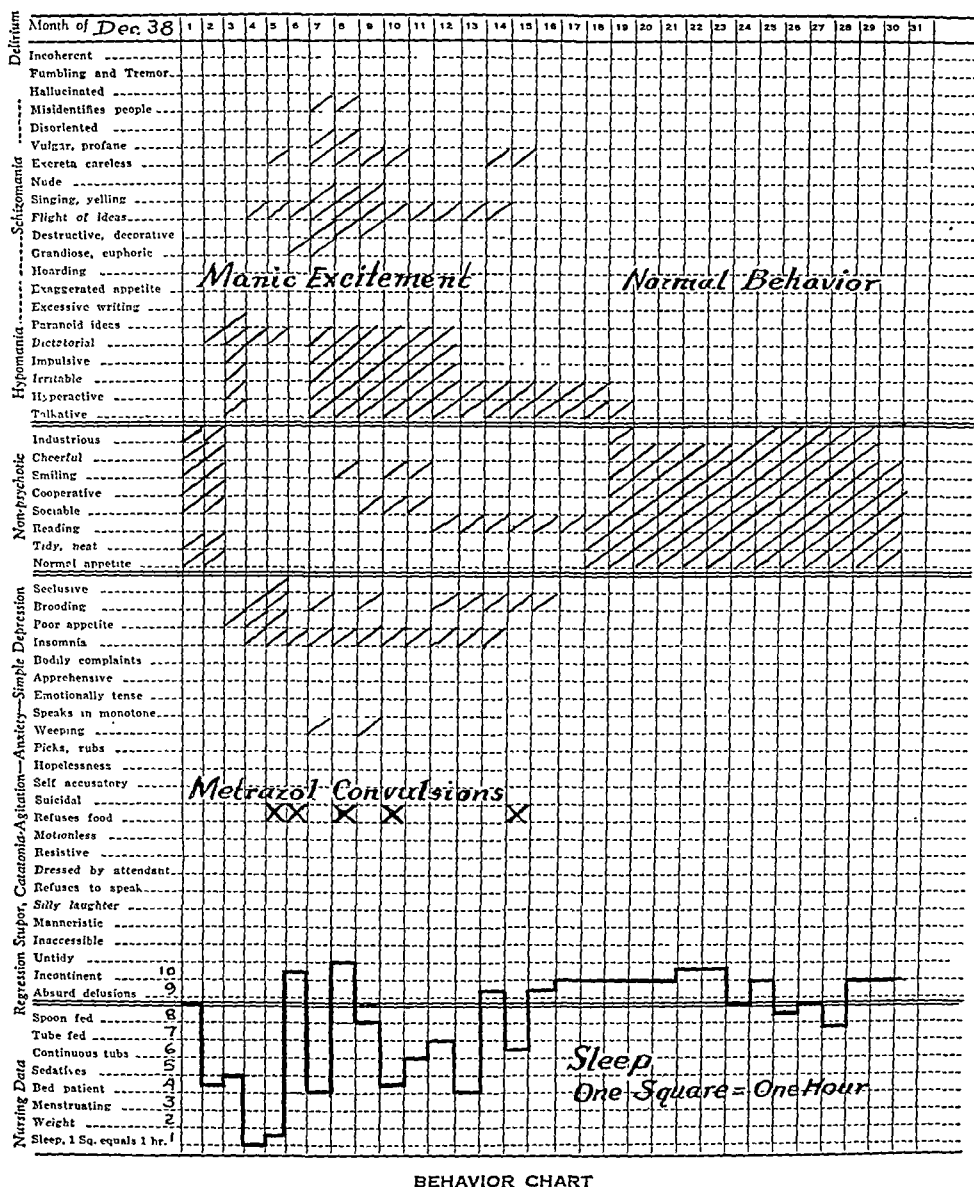

Chart 1.—The abatement of wild excitement and erratic sleep behavior in a young manic patient after five metrazol convulsions.

ness is associated with vague headaches, a peculiar form of dizziness, head noises and inability to concentrate. This so-called headwound syndrome is rarely accompanied by objective signs of organic defect and appears after both trivial and severe trauma to the cranial contents. Although true anatomic change cannot be absolutely eliminated, in general the symptoms resemble those of the psychoneurotic patient who has had no head injury. The belief that the trouble is mainly a psychoneurosis is supported by the fact that many of the patients are involved in controversies over monetary compensation and the insomnia is not infrequently cured when a satisfactory settlement is made. The

the treatment there may be some difficulty in producing adequate sleep, within a few weeks the schizophrenic patient sleeps normally every night, and this may often occur even before the mental picture itself shows any evidence of improvement. While the insulin shock may be a heroic form of treatment, in the long run it is no more noxious than the cumulative effects brought about by the frequent use of the various barbiturates and bromide salts. Schizophrenia is always a grave clinical problem and every aspect of it merits a formidable therapy.

Toxic states are a frequent cause of sleeplessness, particularly those induced by the excessive use of such stimulants as coffee, amphetamine or alcohol. Of the first two little need be said, for the treatment is obvious. It is a little absurd to talk of insomnia in extreme alcoholic intoxication, when the sensorium is completely clouded and many of the vegetative functions are badly deranged. Nonetheless, the confusion, the tremor and the nocturnal excitement call for more than ordinary measures to combat the psychic unrest. The routine as recently outlined by Bowman, Wortis and Keiser⁹ has been the therapeutic procedure of choice of most clinicians. This consists of abrupt withdrawal of alcohol and judicious use of sedatives, with a preference for paraldehyde and a condemnation of morphine. Sodium chloride is administered to combat dehydration, and a high calory, high vitamin diet is provided. However useful this program may be in cutting down the mortality rate, the sleeplessness of acute alcoholic intoxication does not improve until the patient is well into convalescence.

Much more effective is the intravenous use of crystalline vitamin B₁. In nine cases of acute delirium the entire picture of confusion and tremorous excitement was dramatically terminated within five or six days (chart 2). Even more enthusiastic results were reported by Kloster,¹⁰ who gave vitamin B₁ to ten patients in whom delirium tremens had not yet completely developed. One or two hours after the injection of one 50 mg. dose, a surprising improvement was noticeable, and eight of his patients slept quietly the first night.

In our own experience with ten patients, normal sleep returned within a maximum of eight days and only one patient died, his condition having been complicated by osteomyelitis. It is believed that such results are not merely a happy fortuity, and today vitamin B₁ should be looked on as the perfect sedative for delirium tremens. Fifty mg. given intravenously once a day for three or four successive days

Chart 2.—The dramatic response to vitamin B₁ therapy, particularly with reference to sleep, of an acute alcoholic delirium.

is the dose recommended. The only undesirable side effect appears to be a tendency to hypertension.

The use of vitamin principles is not only beneficial in treating alcoholism but is of advantage in treating many other toxic-exhaustive states, such as hyperthyroidism. The patient with thyrotoxicosis is notoriously a light sleeper but may not always offer this as a primary complaint. Frazier and his fellow workers¹¹ supplemented the routine preoperative preparation of hyperthyroid patients with the hypodermic injection of 10 mg. of crystalline vitamin B₁ every other day and

the oral administration of 10 Gm. of brewers' yeast every day. Compared with a control group, which was treated with compound solution of iodine alone, the vitamin-treated patients showed a slower pulse rate and a better appetite and gained weight to such a degree that they were more quickly and adequately prepared for operation.

A serious rival of vitamin B₁ as an ideal sedative in exhaustive states may be ascorbic acid, the vitamin C principle. Lewis¹² discovered that in preoperative thyrotoxicosis the excretion of ascorbic acid was far below normal and did not reach a normal value until after thyroidectomy. Not only did Alexander and his associates¹³ find a low ascorbic acid value for the blood of alcoholic addicts, but this value for many patients with senile psychoses and psychoses associated with cerebral arteriosclerosis approached that of subclinical scurvy. Minski and Constantine¹⁴ found a low vitamin C output in the urine of fifty undifferentiated psychotic patients, even after they had been on an apparently adequate hospital diet for several weeks.

Ordinary insomnia, irrespective of the cause, seems to be readily modified by large doses of ascorbic acid, according to Maurer.¹⁵ He gave from 1 to 3 Gm. of l-cevitic acid daily to more than 100 patients suffering from insomnia. This produced a sound and normal sleep, and the major effects disappeared within twenty-four hours after the medication had been discontinued, not only leaving no undesirable after-effects but in some cases actually establishing a normal sleep rhythm for a week or more.

In view of the propensity of old people to deficiency diseases, massive doses of vitamins B₁ and C should be given to stay the insomnia incidental to cerebral arteriosclerosis and to senile decay. Rather than being treated with large and continued doses of ordinary sedatives, the sleeplessness of cardiac deficiency, of post-infectious cachexia and of all exhaustion states which deplete the nervous system should be approached first with vitamin replacement, which obviously treats a cause rather than a surface symptom.

It is a fine commentary on modern medicine that the treatment of nervousness and insomnia is veering away from the excessive use of the orthodox sedatives, with their toxic potentialities, and that the newer therapies are applied with an eye on the basic or fundamental causes of these disorders. The use of psychotherapy, metrazol convulsions and insulin shock for the strictly psychogenic forms of insomnia and application of the vitamin principles to many toxic and exhaustive states which give rise to abnormal unrest are perhaps prophetic signs that the heyday of drugging and mere masking of symptoms by stupefaction is well on the wane.

Maintenance Diets.—A maintenance diet is one which contains that quantity of nourishment which will maintain the body at its ideal weight; it is the key to the dietetic treatment of obesity because it is the basis from which reducing diets are formulated; success or failure of the latter depends on the correctness or otherwise of the maintenance estimate.—Christie, W. F.: *Ideal Weight: A Practical Handbook for Patients*, London, William Heinemann, 1938.

Council on Physical Therapy

THE COUNCIL ON PHYSICAL THERAPY HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORTS. HOWARD A. CARTER, Secretary.

HOLLAND-RANTOS FEVER BAG ACCEPTABLE

Manufacturer: The Holland-Rantos Company, Inc., 37 East Eighteenth Street, New York.

The Holland-Rantos Fever Bag is intended to prevent heat loss from patients whose temperature has been elevated by various methods. It is 76 by 36 inches in size, weighs about 25 pounds, and is filled with kapok between a rubber-calendered, waterproof and sterilizable lining and a waterproof drill outer covering. The top of the bag may be raised in a tentlike fashion by a bar passed through rings and suspended from the bed, thus permitting the patient some mobility. One slide fastener closes the bag along one side and across the bottom; another closes a U-shaped flap in the center, intended to facilitate attending to the patient's needs. A provision is afforded for taking rectal temperatures by means of an 18 inch opening tied by tapes at the left center. A Russian-style collar may be adjusted to neck size.

Holland-Rantos Fever Bag.

In order to provide evidence for the maintenance of heat by the unit, the firm submitted twelve fever charts from a competent investigator who used this bag in conjunction with an acceptable short wave apparatus to produce the initial heat. The heat was applied by means of a cable from the short wave unit placed underneath the bag and separated from it by two layers of turkish toweling. Some of the same patients were also treated in cabinets energized by electric lights and short wave, and they reported comparable feelings in the two types of apparatus. An average of two hours and thirty-five minutes was required to induce a temperature of 106 F., and this was maintained for an average of four hours and thirty minutes. In ten of the twelve tests the short wave unit was used four or five times during each treatment in order to maintain the

Temperatures Summarized from the Charts

Chart No.	Heat Induction		Heat Maintenance	
	Time	Temperature at End, F.	Time	Temperature Range, F.
1.....	3' 30"	106.0	4' 30"	106.0-106.2
2.....	2' 30"	104.6	5'	104.6-105.5
3.....	45"	102.4	5'	102.4-104.6
4.....	2' 15"	105.8	4'	105.8-107.0
5.....	1' 15"	104.8	4' 45"	104.8-105.8
6.....	2' 35"	105.6	4'	105.6-106.8

temperature. In two cases the fever was held above 106 F. after a single application of short wave diathermy.

From the charts submitted it is observed that the temperature in the bag rose gradually as the rectal temperature did but never rose to as high levels as those of the rectal or cutaneous temperatures. The temperature of the skin did not rise above 103.5 F. Between the head and the foot ends of the bag, temperature differences of 2 degrees F. were noted at times. The humidity in the bag was about 100 per cent. There were no evidences of cutaneous burns, and the blood pressures, pulse rates and respiratory rates were similar to those in other methods of physically induced fever. No evidence of delirium was shown.

The firm also submitted two charts from another physician who used the bag. In an electric cabinet the temperature of one patient was raised to 106.2 F. in about three hours. Then the patient was transferred to the bag, and the temperature was maintained between 105.4 and 107.2 F. for about six hours, after which it fell steeply to 102 F. in the subsequent four hours in the bag. In the other case the fever was generated through

the bag by an electric induction apparatus. One hour and forty minutes was necessary to raise the patient's temperature to 106 F. in the bag and it was maintained between 105 and 106 F. for about five hours with the aid of hot water bottles.

Six other charts were also submitted from a hospital for the firm, giving data on the use of the bag with short wave apparatus to induce fever.

In the first and fourth charts it is to be noted that, one hour after the first application time, short wave was applied a second time for thirty minutes. It is also to be noted that an average of 1.1 degrees F. was gained at various intervals after turning off the short wave current and leaving the patient in the bag. In two of the charts the pulse rate increased continually until the end of the treatment.

The unit was investigated clinically for the Council. The induction period is a little longer than necessary when the bag is used with short wave diathermy, and patients are not as comfortable in the bag as in a cabinet, although, when the bag is so arranged that the top portion is lifted away from the patient by means of the special attachments, patients are not so uncomfortable as in types of cloth bags not so equipped.

In the opinion of the Council, this type of slide fastener bag is as satisfactory as any type of fever bag in affording a means of insulation, but it is still inferior to acceptable cabinets now on the market recommended for the same use.

The device may be used for maintaining the temperature of patients whose fever has been induced by hot baths or by other means when the temperature is not raised above 104 F. and when the length of treatment is not over four hours.

In view of the foregoing report, the Council on Physical Therapy voted to accept the Holland-Rantos Fever Bag for inclusion in its list of accepted devices.

WESTINGHOUSE MODEL 250 SHORT
WAVE ENDOTHERM ACCEPTABLE

Manufacturer: Westinghouse X-Ray Company, Inc., Long Island City, N. Y.

The Westinghouse Model 250 Short Wave Endotherm is intended for routine office practice in medical and minor surgical procedures. It is a portable model which may be obtained with a subcabinet. Cuff, pad and cable electrodes and felt spacers are part of the standard equipment. Surgical accessories and official electrodes are also available. The instrument panel has two separate controls, one for pad, cuff and surgery and one for the coil technic. There is a meter, serving as a combination milliammeter and voltmeter. A forced draft ventilating fan is in the cabinet.

Diagram of circuit.

One tube is employed in a tuned-plate, tuned-grid circuit. The wavelength is 22.4 meters. Both the cable and pad circuits are inductively coupled.

The manufacturer claimed that when measuring with the photronic cell and lamp load method and with an input of 720 watts there is an output of 275 watts. In the calorimeter method, with two and one-half turns of the cable immersed in a 0.3 per cent salt solution and an input of about 740 watts, the output measured was 284 watts.

In the laboratories serving the Council, with the photronic cell and lampload method, the power input under a full load showed a maximum of 735 watts and an output of 292 watts.

When the cable was used with three and one-half turns, a maximum input of 670 watts, the output on a calorimeter was 272 watts. After two hours' continuous operation at an input of 735 watts, the temperature rise in the outside windings of the transformer was 83 C. Although the tests made by the Council and the firm differed in certain details, they were sufficiently similar to substantiate in general the claims made by the firm on the physical performance of the apparatus.

RESULTS OF TESTS

In order to provide evidence for the tissue-heating power of the unit, the firm submitted the data collected by a qualified investigator:

Cuff Technic.—Two cuff electrodes with approximately 0.5 inch spacer under each were wrapped around the thigh with approximately 4 inches spacing between the proximal edges.

Average Temperatures of Six Observations after Twenty
Minutes' Application

Deep Muscle, Degrees F.		Oral, Degrees F.	
Initial	Final	Initial	Final
97.8	104.7	98.7	98.9

Average Temperatures of Six Observations After Twenty
Minutes' Application

Deep Muscle, Degrees F.		Oral, Degrees F.	
Initial	Final	Initial	Final
96.8	105.3	98.1	98.4

Average Temperatures of Six Observations After Twenty
Minutes' Application

Deep Muscle, Degrees F.		Oral, Degrees F.	
Initial	Final	Initial	Final
97.1	103.8	98.4	98.6

Average Temperatures of Six Observations

Minutes	5	10	20	30
Degrees F.....	101.5	106.8	107.3	109.8

The thermocouples were inserted to the full depth of the cannula and the skin temperatures were recorded at a point adjacent to the place where the incision had been made. All treatments were given to the patient's tolerance.

Inductance Cable Technic.—Four turns of the inductance cable were made around the thigh with approximately one-half inch turkish toweling beneath for spacing. Two turns were made high up on the thigh, where approximately 3 to 4 inch spacing was allowed to provide for inserting the thermocouples; then two more turns were taken below the incision.

Treatment Drum Technic.—The treatment drum was applied over the thigh as close to the skin and as nearly over the point where the temperatures were read as the inserted thermocouples would permit.

Official Tests.—A large Chapman electrode was used, drilled to pass a thermometer to allow a mercury bulb to come in contact with the cervical tissues.

A large short wave pad was used as the indifferent or dispersive electrode and connected to the No. 1 pad terminal of the machine. This was placed over the lower part of the abdomen separated from the skin by approximately 3 inches of folded turkish toweling.

The Chapman electrode was connected by a standard 42 inch lead to the No. 3 pad terminal and inserted into the vagina. The thermometer was inserted to contact the cervix and left in position throughout the treatment.

The unit was placed in a clinic, where it was found to operate satisfactorily and to provide ample heating for routine clinical work.

In view of the foregoing report, the Council on Physical Therapy voted to accept the Westinghouse Model 250 Short Wave Endotherm for inclusion in its list of accepted devices.

SATURDAY, SEPTEMBER 30, 1939

THE PROGNOSIS IN SUBACUTE BACTERIAL ENDOCARDITIS

Subacute bacterial endocarditis has for many years been considered practically incurable. A recent review¹ of eighty-eight cases observed at the Wisconsin General Hospital indicated the occurrence of only one healed case. The septic type of subacute bacterial endocarditis, almost invariably fatal, has become so familiar that the group of patients with a mild degree of infection in which there is a chance of recovery has been overlooked. Perhaps the time has come to change the conventional view of this disease.

Capps² has recently reported a study of 139 cases, all followed over a long period of years or to the fatal outcome. Thus one patient, whose condition was first diagnosed in 1910, is today in good health. Eleven patients survived five years or more after the onset of the infection. Included among the recoveries are only those patients who have remained symptom free for more than five years. The guilty organism in all of the cases reported by Capps over a period of twenty-eight years was *Streptococcus viridans*. There were heart murmurs, fever and blood cultures yielding the streptococcus in all these cases, and often embolic phenomena. Some early reports of recovery from subacute bacterial endocarditis were viewed with skepticism; they presented unsatisfactory proof of a correct diagnosis, and some patients had survived so short a time that the appearance of recovery might be interpreted as a remission. There are, however, more authentic reports of recovery. Conspicuous is the report by Oille, Graham and Detweiler,³ who in a short period discovered twenty-three cases of a benign form of subacute bacterial endocarditis, and ten years later at least twenty of them were living. Libman⁴ has studied some of these remarkable cases. Capps tabulates other reports of recovery in his review.

The criteria on which the diagnosis is based are (1) the signs of an active endocarditis, (2) fever, often of low grade, (3) positive blood cultures, most often revealing the streptococcus but sometimes another organism instead, and (4) embolic phenomena, that is petechiae in the skin, red cells or albumin in the urine, enlargement of the spleen, or local symptoms from lodgment of bacteria in the brain, the lungs or the extremities. The most constant observations are fever and heart murmurs. There are, however, many mild cases of subacute bacterial endocarditis which escape recognition because of negative blood cultures.

The incidence of this infection varies year after year, as do other infections. Few cases were observed by Capps from 1910 to 1920. There was an abrupt rise in the number of cases observed in 1922, which reached the peak in 1923. A decrease was observed in the following year; then an irregular number of cases was observed from 1925 to 1937. The experience at the Massachusetts General Hospital from 1910 to 1926 is comparable. From 1910 to 1921 there occurred from two to eight cases a year; in 1922 the number increased to nine, in 1923 to sixteen, in 1924 it fell to eight, in 1925 it rose to fourteen, and in 1926 the number was again down to seven cases. The epidemic in Boston occurred, therefore, in about the same years as did the wave of cases in Chicago. Eight of the eleven cases of recovery reported by Capps occurred in the period from 1920 to 1924. He has not seen a case of recovery since 1924. The patients now considered as recovered with few exceptions were up and around when first seen complaining of loss of weight and appetite, fatigue and palpitation and sweating. They were in marked contrast to the septic appearance of most of the bed patients who died.

The numerous remedies that have been employed in the treatment of cases of subacute bacterial endocarditis in which recovery has occurred is in itself a suspicious circumstance. Transfusion of the blood of donors immunized with the patient's organism has been of doubtful value. Vaccines have failed in extensive tests, and our faith cannot yet rest on any of the several chemotherapeutic products used. Sulfanilamide has been disappointing, although it is perhaps too early to estimate its value. The patients in the Capps series who recovered, as well as most of the ones who died, were given sodium cacodylate by vein, 3 grains (0.2 Gm.) a day, over a period of from six weeks to three or four months. It is impossible to say to what extent this remedy contributed to recovery, but it probably played a minor part. The most important therapeutic measure was prolonged bed rest. The patients who recovered were kept in bed often for three or four months. These products and methods rarely had any constant value in the septic cases with high fever and embolic phenomena. The only hope of a successful outcome lies in discovering the mild cases early, and in the immediate and prolonged enforcement of bed

rest. The patient in the office and dispensary who has a heart murmur and a low fever of undetermined origin may after repeated blood cultures show *Streptococcus viridans*; it is not in the hospital wards that mild cases will be discovered. The elective site for the invasion of *Streptococcus viridans* is said to be in an old rheumatic endocarditis; a patient with a rheumatic heart valve or a congenital heart lesion is peculiarly vulnerable to this infection.

ILLEGITIMACY IN THE UNITED STATES

About 4 per cent of all live births in the United States are births of children who are illegitimate, in that the births are "out of wedlock." The figure is not absolutely accurate, because states vary in the manner of keeping birth records. Several of our states do not classify illegitimate births separately. The figures of the United States Bureau of Census indicate that about 75,000 illegitimate children are born annually, of whom 35,000 are white and 40,000 Negro. The proportion of illegitimate to total births has been estimated to be 39.8 per thousand, with a rate of 20.3 per thousand for the white population and 162.4 for the colored population. Thus illegitimate births occur approximately eight times as frequently among the colored population as among the white. These rates are reflected by those states which have been denominated as public health problem No. 1. For example, the 1936 rates for illegitimate births varied from a low of 11.2 in Utah to 101.6 in South Carolina, 85.4 in Mississippi, 84.4 in Louisiana, 83.4 in Alabama and 83.1 in the District of Columbia. Here is an obvious relation to the racial distribution of the population, similar to the relation observable in the death rates in those states.

Laws relating to illegitimacy vary greatly among the different states. A study of these laws shows that they are not adapted to modern social conditions. Previous attitudes required punishment of the man responsible for the child born out of wedlock and this attitude is still reflected in most legislation. Few laws take into account the desirability of giving a child born illegitimately equal opportunity with other children in its life after birth. The seriousness of this situation is reflected currently in articles published in the *American Magazine* and in *Collier's*, which indicate that our social attitudes are still such as to penalize the child born out of wedlock far beyond any responsibility that should rest on the child itself. Furthermore, the falling birth rate, the increasing desire to obtain children for adoption, and our social attitude toward the unwed mother and the illegitimate child have established exploitation of the unwed mother and of the illegitimate child for commercial purposes. Numerous maternity homes, such as those conducted under the auspices of the National Florence Crittenton Home, the Salvation Army and some religious organizations, maintain high standards of social and medical care, and suitable cooperation with other social agencies. Many private institutions, how-

ever, are conducted for profit and have brought into this field commercialization as despicable as any of that associated in the past with the promotion of fraudulent medicines.

In times of depression illegitimacy increases. The illegitimate birth rate in the United States rose by 12 per cent from 1929 to 1934, at a time when the legitimate birth rate decreased by 11 per cent. Marriages decrease during depression periods, but the figures show that fertility may increase. In families on relief, the birth rates are much in excess of those obtaining in families with economic independence. The extent to which enforced idleness and moral let-down are associated with dependency and relief is a problem to which social investigators might well give attention.

Finally, illegitimacy yields dependency. Fifteen per cent of the total number of children in institutions and in foster homes in 1933 were of illegitimate birth. Many illegitimate children are born of mothers exceedingly young and obviously, therefore, themselves requiring care from social agencies. Girls under 18 years of age make up one fourth or more of all unmarried mothers.

The problem of illegitimacy is not essentially a health problem but one which intimately concerns the medical profession. If our nation has lagged behind in health as some critics assert, it has certainly lagged much further behind in its social attitudes and in its legislation on this problem.

HOSPITAL SCHOOLS

Children who are confined in a hospital for treatment are unable to attend school classes; therefore they present an educational problem. This is especially true of those suffering from chronic or crippling conditions. For such children the hospital school has been developed. Clele Lee Matheison¹ reports a study of 162 hospital schools in the United States and its dependencies.

Hospital schools have been known for many years. The first was founded by a physician, Dr. Knight, of New York City, with his daughter. His home served as a combined school and hospital for crippled children. This school is still in existence. The second hospital school was established in 1882 at Baldwinsville, Worcester County, Massachusetts. The founder was also a physician whose interest in this project was aroused by seeing the cripples brought to the Bellevue dispensary. This institution is also in existence today; it is independent of any state supervision of the educational work and is financed from the hospital budget by the Woman's Auxiliary.

The movement for hospital schools has grown in a haphazard manner. Many of the schools now established have little information as to what others are doing, owing to lack of material on this subject. Laws

1. Matheison, Clele Lee, in cooperation with the Office of Education, United States Department of the Interior: Hospital Schools in the United States, Bull. 17, 1938.

differ with the different states. Private initiative was responsible for promoting the idea in the first place and for later development and financial support. The Rotary International has been one of the most influential organizations in the promotion of this movement. Other organizations have followed suit and are now continuing their influence even to the extent of added financial assistance where the state has already begun to contribute toward support of the hospital school. The development of state educational responsibility has been slow. At present seventeen of the forty-eight states have laws relating specifically to hospital schools for the physically disabled child. The physically disabled adult and mentally deficient patient are not included under these provisions, since the rehabilitation laws of various states are intended to take care of these groups. The laws now in effect contain either mandatory provisions or permissive legislation for the establishment of hospital schools. Some states have both. The mandatory provisions usually provide for crippled children and are optional as far as other physically disabled children are concerned.

Conservative estimate of the number of schools in existence is between three and four hundred, a number entirely inadequate to meet the needs of the number of children requiring their services. The aims of the hospital schools are (1) therapeutic, (2) vocational and (3) to give the child the education to which he is entitled and would receive under normal conditions in the regular schools. Since the education of the physically handicapped child cannot be continuous, such children may show a greater amount of retardation than is found in the regular school. This retardation is not due to low mentality on the part of the hospital school children but is due primarily to the lack of opportunity for education during the hospital stay. There appears to be a need for further study of existing schools and for much additional help so that crippled children may have the education they need to cope fairly with a world which they enter under a disadvantage.

Current Comment

UNNECESSARY SURGERY

Much of the propaganda devoted to breaking down public confidence in the American medical profession in recent years has been devoted to an attack on the medical profession because of the performance of allegedly unnecessary surgical operations. Obviously, this kind of propaganda is never supported by facts or figures but is largely devoted to what has come to be called "a smearing campaign." In contrast is a report recently made available of surgery performed in a Brooklyn hospital. According to figures supplied by Dr. S. S. Goldwater, Commissioner of Hospitals, New York City, major surgical operations were performed in that hospital on 979 patients, exclusive of operations on bones and joints, and fractures and other lesions

of bones and joints were treated to the number of 788. At the same time in this institution sixty-eight patients with possible surgical conditions were treated conservatively without operation, and 117 patients who came into the hospital with surgical diagnoses were not operated on because further study failed to confirm the diagnosis. THE JOURNAL ventures to say that this type of figures could be duplicated in the vast majority of hospitals in this country and particularly in those institutions approved by the Council on Medical Education and Hospitals of the American Medical Association as institutions suitable for the training of interns; moreover, the staffs of most hospitals maintain the same conscientious attitude toward the patients under their care.

HOMICIDE BY WITHDRAWAL OF INSULIN

A person who induces a diabetic patient to discontinue the use of insulin, when the use of that drug is necessary to preserve his life, is guilty of manslaughter if the patient dies as a result of such action. In principle, it is equivalent to withholding insulin from the diabetic patient by physical force. Intelligent public opinion everywhere will approve of the decision of the Supreme Court of Washington, abstracted elsewhere in this issue, branding as a killer a so-called drugless healer whose negligent treatment of a person with diabetes caused death. The court said that such conduct constituted manslaughter. The healer not only assured the patient that insulin was absolutely unnecessary for his recovery but induced him to discontinue a diet prescribed by a reputable physician, limiting the use of carbohydrates. A similar case was reported in the London letter in THE JOURNAL last year.¹ A young school teacher in London had been under medical treatment for diabetes for a number of years. Her condition was satisfactory and was likely to remain so as long as she followed the dietetic instructions of her physician and continued the use of insulin. On the recommendation of friends, however, she went to see an osteopath, who told her that she did not have diabetes but was suffering from anemia, and the patient was persuaded to discontinue the use of insulin and to limit her food for a period of several days to orange juice every two hours. As a result of this treatment she died and the osteopath was convicted of manslaughter and sentenced to six months in prison. In the United States, persons without scientific training and utterly ignorant of the causes, diagnosis and treatment of disease, faith healers and other incompetents are permitted either by sanction of law or by toleration to assume responsibility for the treatment of sick human beings. As long as they are permitted to do so, tragedies such as the one that occurred in Washington must and will occur all too frequently. Here is a condition that is being given scant consideration in the current proposals for promoting the health of the people. The most fundamental factor in every consideration of medical service is the scientific qualification of those who render the service.

ORGANIZATION SECTION

MEDICAL FEES FOR OBSTETRIC SERVICE

R. G. LELAND, M.D.

Director, Bureau of Medical Economics, American Medical Association
CHICAGO

Emoluments received from the practice of medicine do not involve the transfer of a tangible material commodity. A physician's professional relations with the public are classified by economists as personal service. They are not subject to resale; therefore they have no basic exchange value. These personal services differ in many ways from those furnished by the other professions. The attorney, in civil cases for instance, is concerned with tangible values, subject to legal action. Even in the majority of criminal cases he can bargain in advance for his fees, and he can secure himself in almost any professional transaction by a retainer fee. The architect or engineer is concerned with structures subject to a lien or other legal action. But it is not customary for the physician to pledge himself by the acceptance of a retainer fee, nor can he secure a lien on the human body.

The medical profession is concerned with the development and application of efforts to conserve human values. Economists, as well as physicians, recognize the inherent difficulties in arriving at any accurate or even approximate statistical measurement of vital values, such as health and life. Vital values, however difficult to determine, must be stated not only in terms of the person valued but also in terms of those for whom the individual has value. Such determinations must include the worth of the individual to himself, his family and his dependents, his business associates, the state and the world or society at large. Not the least among these considerations should be the part which the individual can and should perform in maintaining local, national and world population increments. It should be self evident that the values ascribed to an individual depend on his ability to function as a normal, healthy member of society.

An understanding of these vital values and the dissimilarity of individuals and their physical and mental reactions is an important part of the practice of medicine. Because of these variables, good medical care always has been and always will be an individual service involving a close, personal, confidential relationship between the patient and the physician of his choice. Thus, health requirements and the means for their maintenance or improvement cannot successfully follow the assembly line technic of industry, and the cost price principle of business and industry cannot be used by physicians in establishing fees for their services.

In the field of obstetrics the midwife appears to be one of the most ancient of professional figures. During the early periods of medicine, physicians were accustomed to leave the care of women's diseases and obstetrics to midwives, and indeed this was the prac-

tice in America until shortly after the middle of the eighteenth century, when William Shippen first removed the prejudices in opposition to male accoucheurs.

FEE SCHEDULES

When we turn to early American medicine, we find that such medical legislation as the colonies had in this period was, as in the Code Hammurabi (2250 B. C.), mainly concerned with the momentous question of fees. An example of one of these early American regulations is to be found in volume 4, Hening's Statutes at Large of Virginia, page 509, "An Act of Regulating the Fees and Accounts of the Practice of Phisic," but no mention is made in the list of allowances of any fees for obstetrics.

The account book of John Warren, dated May 1782, contains a list of charges entitled "List of Fees of the Boston Medical Society." This list contains the item "for midwifery, 2 pounds 8 shillings." In 1817 the Boston Medical Association listed charges for midwifery during the day as \$12 and at night \$15.

The New York City Fee Bill of 1816, which was a renewal of that of 1790, differed from the Boston Fee Bill in the greater latitude of charges and the larger number of items. Midwifery in New York was more expensive than in Boston, the charges being from \$25 to \$35 in common cases and from \$35 to \$60 in tedious or difficult cases.

Philadelphia, with medical talent unsurpassed in America, had a relatively low fee bill. In 1834 the charge for midwifery was from \$8 to \$20—nearly comparable to the charges in Boston but less than the fees in New York City. In 1833 the midwifery charges in Washington were \$12 in the day and \$15 at night. In the small towns, medical fees were much lower; e. g., in Lowell, Mass., the charge for midwifery was \$5.

The Ohio legislature at its session of 1836-1837 granted a charter to "The Lebanon Medical Society." One of the first acts of this society was to adopt a fee table which included the items "common cases of parturition \$5, protracted or difficult \$5 to \$20."

In 1871 the Omaha-Douglas County Medical Society adopted a fee schedule which lists "obstetric fees, ordinary case of not over six hours \$20; for each hour's attendance over six hours \$1."

Although the index numbers of prices and money values for the early decades of the United States are not accepted as having a high degree of accuracy, there seems to be little doubt that the purchasing power of money at that time was at least 100 per cent greater than it is today.

A study of the development of fee schedules for medical services during the early period of American history reveals some of the factors that physicians of those times considered, in an effort to arrive at fair

Read before the Public Health and Hospital Administrators Section of the American Congress on Obstetrics and Gynecology, Cleveland, Sept. 14, 1939.

charges for their services. It was recognized that distance, time, economic status, educational attainments and professional skill should be considered in fixing medical fees. These same factors are still important in determining charges for medical care, but, with the perfection of new methods and technics, costly drugs and procedures in diagnosis and treatment, and the growing appreciation of these new developments on the part of the public together with the increasing complexity of modern society, new factors have added to the difficulty of establishing medical fees which would permit the use of new and sometimes expensive procedures and would at the same time be fair to the patient.

Wherever fee schedules have been adopted, they have represented the considered opinion and the established custom of the physicians in small areas, usually cities or counties. Moreover, the physicians in many parts of the United States still prefer to follow common custom rather than an adopted schedule of fees.

The Bureau of Medical Economics has assembled the fee schedules reported to have been adopted by 559 county or district medical societies in forty-six states. The composite list of fees compiled from these schedules comprises 606 items. This composite list, when compared with the small number of items listed in the earliest fee bills, provides some index of the developments in medical science and practice over the past 150 years.

The items in this composite list of fees under the classification "Obstetrics" include:

- Normal delivery—one child.
- Normal delivery—more than one child.
- Induction of labor.
- Abnormal presentation or position.
- Version.
- Premature delivery.
- Delivery by forceps.
- Treatment of placenta praevia, convulsions, or other abnormalities or complications.
- Treatment of abortion.
- Treatment of miscarriage.
- Craniotomy or embryotomy.
- Ectopic pregnancy.
- Delivery of placenta only.
- Cesarean section.
- Severe postpartum hemorrhage.

In some localities the charges for antepartum and postpartum care are in addition to the fees listed for delivery, but in other places it is impossible to judge from the fee schedules whether or not the stated fees for obstetrics include antepartum and postpartum care.

Available source material includes 491 schedules which give the charges for "normal delivery—one child." The range of minimum charges in these schedules is from \$10 to \$75, with a median of \$25. Maximum charges for the same items are given in 105 schedules, with a range of from \$15 to \$1,000 and a median of \$50.

The medians of minimum and maximum charges for other obstetric services are given in the accompanying table.

These median charges represent a position average. They are not influenced by the size of the fees above and below them but represent the central tendency in a series of high and low fees.

The fee bills of early American medicine and the 1938 fee schedules of county medical societies give some idea of the variation in charges for medical services in dif-

ferent communities. A casual comparison of the charges today and those of a century ago indicates that, in general, the value ascribed to medical services by physicians has changed but little during the century. However, when it is realized that during the early part of the nineteenth century the purchasing power of money was about 100 per cent greater than it is at present, it is clear that medical fees today are actually far below those of the early decades of the United States.

Although it can be shown that many of the basic charges for medical services have remained almost stationary over a century or more, the aggregate of medical fees has increased in the wake of a continuously accumulating fund of medical knowledge and a multiplication of the number and nature of available medical services. The new technics of diagnosis and the new methods of treatment have not only provided greater assurances of prevention or of recovery from disease but they have also introduced new procedures in medicine which are sometimes costly and which could not have been included in earlier fee schedules.

DIFFICULTY OF GUARANTEEING GOOD MEDICAL CARE FOR EVERY ONE

As the number, variety and value of medical services have increased, the public has gradually grown to demand all and sometimes more than the medical profession could provide in the care of some classifications of disease. Indeed, in the face of the most gratifying health conditions ever reached by any 130,000,000 people at any time, made possible by the methods of medical practice that have been maintained and advanced in the United States, the public has only recently been surfeited with costly publicity and propaganda. The chief object of this would appear to be to create in the public mind a growing dissatisfaction and a waning confidence in present medical services, to bring discredit on the humanity, competence and services of the health professions, and to advance a new form of medical practice.

It may be well to cite some of the conditions which make it difficult, if not impossible, to guarantee good medical care to every one. Genes and germs are still responsible for certain conditions that are beyond human control. Accidents and ignorance are still operating to deprive individuals of legs, arms, sight and other health attributes. Superstitions and personal preferences still place good medical care beyond the desire of some people. Indeed, there have been instances in which court orders have been necessary to permit the use of medical science to save the lives of children.

Predictions that definite numbers of persons can be spared the experience of illness or can be guaranteed a longer span of life are without any basis of fact. Too frequently those who make such predictions fail to consider the human factor. Blame for many individual health defects, if blame is to be attached, belongs to the individual himself. No one, however skilled in medicine, and no method, however perfect, could keep some people continuously in health.

Above all, technical minds should realize that, while expansion and improvement of the public health and curative service in the nation are long overdue, the individual has some responsibility for his health and that of his family. There is a possibility that medical science is being pressed too hard for cures of hereditary,

constitutional and neglected disease. We must not lose faith in the ability of the individual to accomplish some measure of betterment himself in social and health matters, if given the enlightened guidance of health education.

When all these and many other factors are considered, it should be evident that the mere fact of the availability of medical services gives no assurance that such services will be used by persons who need them. Moreover, it must be admitted that even the most skilled physicians cannot accomplish the impossible.

Medical ethics, which places service to humanity above the income determining elements of medical practice, has survived as the strongest stimulus to good medical service.

FORCE OF CUSTOM IN FIXING FEES

From whatever point of view the problem of charges for medical services is approached, the conclusion is always reached that the dominant force in fixing fees is custom. Every attempt to establish an hourly rate as a "value of services rendered" is complicated, if not entirely thwarted, by the introduction of such "vital values" as life and health, which defy market valuations.

Some forms of organized medical service have attempted to follow industrial models and have fixed their charges according to the "cost of production." The determination of the cost of production in medicine is possible only as far as the items priced are already standardized on industrial lines. For example, a hospital can calculate the cost of rent, interest on invested capital, depreciation of buildings and equipment, expenditures for food and other commodities, but the medical services rendered in the hospital do not seem to permit of cost analyses by any accounting or valuation technic known at present.

The custom-fixed measure of the value of medical services is far from rigid. Wide variations by individual physicians for individual patients are common; this is known as the "sliding scale" of fees, by which charges are varied according to the patient's ability to pay. Moreover, that principle of medical ethics which states that "the poverty of a patient and the mutual professional obligation of physicians should command the gratuitous services of a physician" is observed by the medical profession now, as in the past. Indeed, medical care is one of the few necessities of life still available to those who have no money, but the volume of demand for free services during recent years has become too great for physicians to bear alone.

It is not claimed that the present system of charges for medical care is perfect, but the overwhelming majority of physicians are endeavoring to render good medical services at fair fees. Unfortunately, an occasional unwarranted charge is publicized as if it represented the general rule. Moreover, it must be recognized that human nature, illness and the treatment of disease cannot be standardized, and therefore charges associated with attempts to apply the mass production principle in medicine do not always represent good values in medical care.

The salaried obstetrician in a teaching institution is an example of the exception to the general rule of fee for service. Such physicians are animated by an approach to a perfect performance made possible by the favorable conditions created and maintained by these

institutions. The primary motive of teachers of obstetrics is devotion to the improvement of methods which will advance the general practice of obstetrics and enhance the benefits to mothers and their children. These conditions and motives could not be made a part of a general scheme to place all obstetricians on salary.

Obstetric practice today is immeasurably superior to the midwifery care of 150 years ago. There is every reason to expect that in the field of obstetrics, as in other special fields of medicine, new procedures and services will continue to be developed for the benefit of new generations and their mothers. These new procedures and services cannot be provided without cost to some one. The extent to which such benefits are to be considered as regular services for all normal obstetric cases or special services for the exceptional cases cannot be determined as a hard and fast rule. Neither is it possible, under a democratic system of government, to compel expectant women to consult a physician and to remain under his observation from the first sign of pregnancy, even though all mothers and children might benefit thereby.

Median Charges for Obstetric Services

	Minimum	Maximum
Normal delivery, more than one child	\$ 45.00	\$ 100.00
Induction of labor.....	50.00	500.00
Abnormal presentation or position...	30.00
Version	50.00	100.00
Premature delivery	32.50	150.00
Delivery by forceps	40.00	100.00
Treatment of placenta praevia, convulsions or other abnormalities or complications	50.00	125.00
Treatment of abortion.....	25.00	50.00
Treatment of miscarriage.....	25.00	50.00
Craniotomy or embryotomy.....	50.00	200.00
Ectopic pregnancy	150.00	1,000.00
Delivery of placenta only.....	15.00	50.00
Cesarean section	150.00	500.00
Severe postpartum hemorrhage.....	50.00	125.00

Much more progress than is often admitted has been made in obstetrics. Further progress will depend on scientific research, the development and maintenance of confidence in the independently practicing physician, and education of the public to its responsibility in the prevention and control of abnormal obstetric conditions.

No system of payment for obstetric and other medical services can be completely and successfully separated from the varying human natures that will require medical attention, or the trained men and women who must render the services. No obstacle should be erected to discourage a continued study of improved methods of distributing medical services, or the operation of the principle that, in whatever way the cost of medical services may be distributed, it should be paid for by the patient in accordance with his income status and in a manner that is mutually satisfactory.

Any discussion of medical fees suggests that serious consideration be given to the broader and more important issue of the ability of the family to provide itself with the necessities of life. Obstetric care, however ideal, complete and reasonable in cost, cannot be a substitute for the food, clothing, heat and shelter that are essential to both mother and child. Interest in the size and the method of payment of obstetric fees should not, therefore, dispel a serious concern over the family's general economic status.

GRADUATE MEDICAL EDUCATION

A PROGRESS REPORT OF THE FIELD STUDY ON GRADUATE MEDICAL EDUCATION IN THE UNITED STATES
BEING CONDUCTED BY THE COUNCIL ON MEDICAL EDUCATION AND HOSPITALS

OHIO

COMMITTEE ON EDUCATION OF THE OHIO STATE
MEDICAL ASSOCIATION

At the 1936 annual meeting of the Ohio State Medical Association, the constitution and by-laws of the association were revised to provide for a new representative committee, known as the committee on education, composed of five physicians appointed for five year terms. The purpose was to extend the educational activities of the association for the benefit of its members and of the public. Dr. Clyde L. Cummer, Cleveland, has been chairman of this standing committee since its inception. The committee was empowered to select subcommittees, subject to the approval of the council of the association. Four such subcommittees were selected, each headed by a member of the committee on education: (1) regional postgraduate lectures, (2) speakers' bureau, (3) district meetings and (4) public health education. The first and second subcommittees have been concerned largely with graduate instruction.

Regional Postgraduate Lectures.—The subcommittee on regional postgraduate lectures is now composed of twelve members. Continuity of its membership is provided, making possible a continuous program of instruction. The subcommittee acts as a coordinating agency and in an advisory capacity to other committees of the association. The work of this subcommittee is essential in the development of the state association's graduate program.

A five year program of postgraduate education was begun in October 1937 after extensive studies had been made of similar activities of other states. Seven cities in five regions of the state were established as teaching centers, in each of which there are ample clinical facilities. This was the state association's response to the expressed need of the profession for postgraduate programs of practical value given in proximity to the homes of physicians. A series of eight fortnightly sessions of two lectures and discussions each were given the first year and a series of six sessions of lectures constitute the second year's course being given this autumn—the time of year when all sessions are now held. Identical courses were arranged for all regions once each year.

Graduate programs were arranged in sequence and provided for continued consideration of subjects in the fields of medicine, pediatrics, obstetrics and surgery and topics of special interest chosen in proportion to their relative importance in the general practice of medicine. A regional committee was selected in each locality with representatives from each county medical society. The postgraduate lecture course was organized separately from the regular meetings of councilor district societies, and the regions selected for graduate courses were not identical with district areas.

The subjects were selected by the committee on education and the subcommittee on regional postgraduate lectures according to the needs of practicing physicians. Included in the first year of instruction were arthritis, dermatology, diabetes, gynecology, heart and intestinal disease, infectious diseases including pneumonia, poliomyelitis, syphilis and tuberculosis, antepartum and postpartum care, and management of pregnancy, psychoses and urology.

Subjects chosen for the second year included appendicitis, asthma, cancer, cardiovascular disease, obstetrics and gynecology, ophthalmology, pediatrics, poliomyelitis, proctology and syphilis.

Lecturers were chosen from physicians within the state and included faculty members of the Ohio medical schools. An effort was made to select lecturers who were able to present scientific and clinical discussions in a practical manner. Their names were listed by the speakers' bureau, which completed its organization during the first year. There are now available 300 physicians.

At the end of the first year all proposed regions of the state had been covered and the total cost, including administrative

expenses, was approximately \$2,783. This amount included expenses of printing programs and other announcements, publicity, postage, rental of halls and traveling expenses of instructors who gave their services gratuitously. Without the wholehearted cooperation of volunteer lecturers, the program would not be possible as now organized. Sixty-six members of the association had given lectures to physicians from seventy-seven counties during the year and 1,452 physicians, chiefly of the 6,404 members of the Ohio State Medical Association, had enrolled. There are 9,117 physicians in Ohio. Names of physicians attending these lectures were published in the journal of the state medical association. By increasing the annual dues of the state medical association from \$5 to \$7, it has been possible to finance the graduate program without charging registration fees.

The state association's graduate program has been developed by the committee on education and its subcommittee on regional postgraduate courses with the approval of the council of the association. Details of organization and administration, stimulating physicians' interest in continuation study and other matters concerning publicity, promotion and local arrangements, have been encouraged and developed by the executive officers of the association, assisted by the local committees on arrangements.

Speakers' Bureau.—The subcommittee on the speakers' bureau, Dr. Russel G. Means, Columbus, chairman, was organized by the committee on education to provide competent speakers for the regional postgraduate lectures and to aid local societies with their programs. Physicians who were well qualified to present effectively modern points of view were invited to participate in the state association's activities.

A cross index file has been developed according to subjects and the locations of speakers. The most successful lecturers thus far have been those accustomed to public speaking, able to talk fluently and forcefully without manuscript and with only occasional reference to notes. It has been possible to obtain speakers with extensive professional experience who give in effect dry clinics, although clinical material has not as yet been utilized.

On completion of the work of this special subcommittee in 1937 and after the bureau had begun to function effectively, the committee was discontinued and the executive secretary of the association was designated as manager to conduct the routine activities of the bureau.

District and Annual Meetings.—The subcommittee on district meetings was organized following the recommendation of a special committee of the council, of which Dr. J. H. J. Upham was chairman. Since 1935 the council has made appropriations to provide annual subsidies of \$200 for each district society to aid it in securing speakers and for promotional activities. The state association exercised some general supervision over the scientific phases of the district meetings. This was to insure adequate programs, suitable meeting places and proper publicity. A pamphlet has been prepared for distribution to district society officers which suggests the fundamental factors in a successful district meeting. Thus interest in district meetings has been renewed to the extent that this year the council discontinued the district subsidies, nominal registration fees now financing these meetings, and dissolved the subcommittee on district meetings, it having served its original purpose of reviving the district meeting set-up.

The annual meeting of the Ohio State Medical Association is held in one of the larger cities of the state over two days each year. Seven guest speakers and about seventy-five Ohio physicians participated in the 1939 program, at which twelve round table conferences were an innovation. Registration of physicians at the annual meeting approximates 1,500.

Public Health Education.—The subcommittee on public health education, of which Dr. Carl A. Wilzbach, Cincinnati, is chairman, continues to cooperate with official and nonofficial health

agencies in providing the public with information regarding public health and preventive medicine. Subjects are recommended by this subcommittee to the subcommittee on regional postgraduate lectures and, when desirable, subsequent talks are presented to the public.

ACADEMIES OF MEDICINE

In several sections of the state, county medical organizations have provided postgraduate courses. Some of these have been intensive, compact series of lectures given in one or two day periods once a year, while others have consisted of a series of from ten to twenty one hour lectures in general and special subjects over several days. The metropolitan areas with their ample clinical facilities supplement the state association's graduate activities for physicians practicing in the more sparsely settled areas of the state.

One of the best known programs given in metropolitan areas is the series of postgraduate lectures conducted each year by the Cleveland Academy of Medicine. In 1937 the academy's committee on postgraduate course, Dr. R. L. Haden, chairman, adopted definite principles. These were that lectures be continuous, unified as to subject, with careful selection of speakers, and that they be limited to ten talks given at weekly intervals each year. The courses were open to all physicians without registration fee. Continuity of personnel in succeeding postgraduate committees has assured that each year's program fits into a general educational plan.

The academy's postgraduate course for 1939 included lectures in treatment, vitamins and endocrine disorders. Lectures given in the auditorium of the Allen Memorial Library Building from 5 to 6 p. m. during January, February and March were attended by 498 physicians. Notices for these programs were sent to physicians in the fifth district, which includes Cuyahoga, Lake, Geauga and Ashtabula counties.

A three to five day annual postgraduate program has been held in Toledo since 1923. This is sponsored jointly by the Toledo University and the Academy of Medicine of Toledo and Lucas County. Usually a symposium on one subject constitutes the lecture program. Other one day postgraduate programs have been given by the academy since 1934 in collaboration with the university. A fund is available for graduate medical education given under the auspices of the university. No registration fees are charged.

In April 1939 the four day postgraduate course held in Toledo was devoted to lectures and clinical pathologic conferences on gastro-enteric diseases. A guest lecturer participated in the sessions, which were attended by 125 physicians. Dr. James A. H. Magoun was chairman of the postgraduate program committee.

The Columbus Academy of Medicine presented its first postgraduate day in June 1938. Three guest speakers participated in a general program of six lectures. No registration fees were charged. In 1939 two guest lecturers contributed to the program and 125 physicians attended.

The Lima and Allen County Academy of Medicine has held a postgraduate week each year since 1930. One or more guest speakers participate. The annual attendance approximates 150 physicians.

GRADUATE ACTIVITIES OF OTHER METROPOLITAN MEDICAL SOCIETIES

In Youngstown the Mahoning County Medical Society has held a postgraduate day each year since 1928. This program is designed for physicians practicing in the vicinity, but it attracts many from surrounding counties. In 1937 a series of eight weekly lectures in pathology was given. In 1938 a postgraduate day was conducted by three guest speakers. These lectures were attended by 487 physicians.

In 1939 the postgraduate day was presented by four members of a medical faculty on general subjects of medicine. A registration fee of \$5 has been charged.

Beginning in 1935 the Summit County Medical Society sponsored the first of a series of four postgraduate days in Akron hospitals. This was to enable practicing physicians to study special practices and to obtain from them points of view on general medical problems. The initial meeting was attended by

180 physicians. For three years before, graduate programs had been held in a local hotel and were participated in by out of state speakers.

Postgraduate days have been held in Canton at which guest speakers participate in a series of lectures usually devoted to a general subject of medicine.

MEDICAL SCHOOL PROGRAMS

During March 1939 the Western Reserve University School of Medicine and the staff of the City Hospital of Cleveland offered practicing physicians a lecture course on recent advances in medicine, surgery and special subjects. The auditorium of the city hospital was used three days each week during midday. Periods were allowed for discussions following twenty lectures on such subjects as endocrinology, gynecology, heart disease, tuberculosis and other diseases of the chest, diseases of children, diseases of the skin, diseases of the blood, metabolism and vitamins. From thirty to forty physicians were in attendance. A similar program is to be given in October 1939. No registration fees are charged.

A course of eight lectures on various aspects of syphilis was given over a period of eight weeks during the spring of 1938 and 1939 under the auspices of Western Reserve University, the United States Public Health Service and the Ohio State Department of Health. Lectures were held in the auditorium of the library. Members of the university faculty and health officers participated in the instruction. A full time three months course in syphilis has been available at the medical school also. Physicians have had the opportunity to enroll for shorter periods by selecting one or more weeks of instruction on a part time basis. Participation in clinical exercises, laboratory diagnosis and pathologic and round table conferences were included. No registration fees were charged. Twenty-seven physicians have enrolled.

The Ohio State University College of Medicine has held annual three day graduate assemblies in Columbus since 1934 for physicians residing in central Ohio. Dr. Russel G. Means has been chairman of the faculty committee on postcollegiate instruction for the past five years. Summaries of recent contributions to medicine by members of the faculty, dry clinics, brief reports and round table discussions have been included. General and special clinics, medical rounds and clinical pathologic conferences constitute the varied program, which was participated in by four guest lecturers in 1939. Attendance has ranged from 190 to 300 physicians. A fee of \$2 is charged for registration and for a copy of the proceedings of the assembly.

The University of Cincinnati College of Medicine each year has provided one week of postgraduate instruction in otolaryngology. This course is available to practicing otolaryngologists and includes anatomic studies. Classes are limited to twenty-five. A tuition fee of \$60 is charged. In addition there is an annual alumni day at which guest speakers participate.

OHIO DEPARTMENT OF HEALTH

From May 1937 to February 1939 the Bureau of Child Hygiene of the Ohio Department of Health offered instruction during one afternoon and evening in fourteen counties of the state. The first courses were given in southeastern Ohio. Obstetric instruction was given in eleven centers and pediatric talks in eight. The Ohio State Medical Association and the various county medical societies assisted on details and publicity. Subjects for discussion were selected by the bureau of child hygiene. Lectures, clinics and symposiums and round table discussions were attempted in public buildings such as churches and sometimes in hospitals by instructors from within and in one case from outside the state. Clinical demonstrations were provided at two of the medical schools. Instruction has included consideration of endocrinology, vitamin deficiencies, blood dyscrasias, infant feeding, children's dentistry, infectious diseases and eclampsia, toxemias, instrument deliveries, analgesics and hemorrhages. Approximately 383 physicians registered in pediatrics and 278 in obstetrics. No registration fees were charged, since these courses were financed with social security funds. Each speaker was paid an honorarium and traveling expenses.

OTHER GRADUATE ACTIVITIES

The Frank E. Bunts Institute has offered since November 1935 three day programs at the Cleveland Clinic three times each year. These courses are open to graduates of approved medical schools. Registration fees have varied from \$5 to \$10. Symposia on subjects of general or special interest have been included, such as gastro-enterology, genito-urinary disease, endocrine disorders, diseases of the skeletal and nervous, blood and cardiovascular systems, and benign and malignant tumors. Lectures, clinics, demonstrations and exhibits have been offered. One or two guest speakers may participate. From 105 to 142 physicians from six to eight states register for these programs.

More comprehensive courses in ophthalmology and diseases of the ear, nose and throat have been given also.

The Cleveland Medical Library Association occupies the Allen Memorial Library Building adjoining Western Reserve University. Since 1933 membership dues have been reduced, and other sources of income and assets of the association have proved adequate. At present there are 487 members and, while any physician may use the library, only members can withdraw reference material. Membership dues are \$10, junior and non-resident membership being \$5. There were 53,681 volumes and 444 files of periodicals available in 1938. During that year 12,828 visits were made to the library, the majority by non-members.

OFFICIAL NOTES

COUNCIL ON INDUSTRIAL HEALTH

The fourth meeting of the Council on Industrial Health took place July 8 at the Association headquarters. Those attending were Stanley J. Seeger, chairman, Harvey Bartle, Leverett D. Bristol, Warren F. Draper, Leroy U. Gardner, Henry H. Kessler, Anthony J. Lanza, Robert T. Legge, C. W. Roberts, Clarence D. Selby, Roscoe L. Sensenich (ex officio), Olin West (ex officio) and Carl M. Peterson, secretary. Transactions of interest to the profession were as follows:

1. The Committee on Rules presented for discussion precepts which should guide the Council in its relations with other professional and nonprofessional agencies interested in improved standards and conditions relating to industrial health. A list of these agencies was ordered to be prepared.

2. The Committee on Nomenclature reported progress in its compilation of terms used in industrial health and related fields. It is expected that a complete draft will be available before the end of the year.

3. The Committee on State Associations reported that the Council is in regular correspondence with thirty committees on industrial health or related groups in the state medical associations. It was recommended that continued effort be made to complete the roster of committees in the state medical organizations and to suggest to those already in existence that, as activities expand and membership increases, the highest caliber of personnel be sought after.

In the conviction that some effective means of interchange of ideas and information by the Council and the state committees would enhance organization, provide a measure of uniformity of action and stimulate wider initiative, the Council agreed to continue publication of an industrial health bulletin to be mailed from time to time to state committees and other interested groups. Through this bulletin it is expected that objectives may be more rapidly realized.

It was also decided that effort should be made to urge the attendance of members of state committees and officers of state associations at the next Annual Congress on Industrial Health, at which time a round table discussion dealing with urgently pressing problems would be undertaken.

4. The Committee on Education and Publications reported that it is continuing to gather information about undergraduate, graduate and postgraduate education in the theory, organization and practice of industrial health.

The necessity for formulating a publication program through the medium of THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION was emphasized, in order to keep the profession apprised of the Council's activities and to meet the need for special information on industrial health subjects.

A canvass of state medical societies revealed almost complete neglect of industrial health as a subject for continuation studies under the auspices of committees on postgraduate medical education. It was realized that the objectives of the Council would be enhanced if a definite program of postgraduate study could be formulated. The Council resolved, therefore, to prepare a syllabus on postgraduate education and that as soon as an acceptable one had been developed the committees on industrial health in the state medical associations would be notified. It was also ordered that the Council on Medical Education and

Hospitals be notified of these activities in order that its advice and assistance may be secured and in order that that Council may submit recommendations directly to committees on postgraduate medical education in the state associations.

The committee further reported that authoritative papers on pneumoconiosis, syphilis in industry and medical organization in industry are in the process of preparation, shortly to be available for publication.

5. An extended discussion on industrial health and its place in social security legislation occurred, following which the Council passed a resolution to be referred to the Board of Trustees which expressed the conviction that industrial hygiene affairs should continue to reside in the bureaus of industrial hygiene in the federal and state health departments but that recognition should be given to the desirability for cooperation with as well as assistance from other established agencies interested in this field having facilities for enforcement and regulation.

6. The relations between the Council on Industrial Health and the Section on Preventive and Industrial Medicine and Public Health were discussed. No action was taken pending receipt of information on an investigation to be conducted by a committee of the section designed to improve interest on the part of the medical profession in the activities of this section.

7. A committee was authorized to formulate a set of principles expressing concisely the relations which physicians should establish in industry with employees, employers and one another.

8. The Council discussed the Wisconsin Physical Examination Program as adopted by the industrial commission in that state. It was agreed that plans for industrial physical examinations in the states ought not to mature without consultation with official representatives of organized medicine. Extension of occupational disease compensation legislation will probably increase the demand for physical examination facilities, particularly in the smaller factories. The special requirements of these concerns can readily be supplied by the practicing profession if suitable information is provided. It was therefore thought desirable to investigate the possibilities for field activities in conjunction with state and county medical societies in anticipation of increased demands for industrial physical examination.

9. Reference was made to the superior methods used in Great Britain for reporting and recording the incidence of occupational disease in contradistinction to the futility of attempting to obtain comparable reports on such matters in the individual states at present. Although no specific action was taken, further information is being requested at the present time from such organizations as may be presumed to have considered these matters.

10. The Council undertook to hold its second Annual Congress on Industrial Health Jan. 15 and 16, 1940, in Chicago. It was recommended that symposia on syphilis in industry, physical examinations in industry, disability evaluation and rehabilitation be arranged.

11. A special Industrial Health issue of THE JOURNAL having been authorized, responsibility for the Council's contributions was assigned to the Committee on Education and Publications.

12. A resolution was adopted petitioning the Board of Trustees for further assistance in the development of educational exhibits on industrial health to be available to the profession through the state medical societies.

WOMAN'S AUXILIARY

THE 1939-1940 HYGEIA CONTEST

The American Medical Association offers \$300 in cash prizes to the county and state auxiliaries obtaining the largest number of subscription credits to *Hygeia* during the months of October, November, December and January. The \$300 will be divided into the following cash prizes:

County Auxiliary Prizes

The county auxiliary societies will be equally divided into four groups of 100 societies each, the first group with a membership of from one to thirteen; second, from fourteen to twenty-three; third, from twenty-four to forty-two, and, fourth, those with a membership of forty-three or more.

Three cash prizes will be given to each group: first prize, \$35, second prize, \$20, and third prize, \$10.

State Auxiliary Prizes

Two cash prizes will be given to state auxiliaries that have the highest rating based on their paid auxiliary membership and *Hygeia* credits obtained: first prize \$25, second prize \$15.

Last year the contest covered only the months of December and January. The three cash prizes of \$50 each were won by Union County, Ark., Berks County, Pa., and Cook County, Ill. This year the time has been increased to four months and the cash prizes to \$300.

For years the Woman's Auxiliary of the American Medical Association has recognized as one of its chief activities the promotion of the distribution of *Hygeia* through schools, parent-teacher organizations, boards of education, industrial plants, welfare workers, study clubs and similar bodies interested in education.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

ARKANSAS

Norman Baker Surrenders to U. S. Marshal.—Norman Baker, who moved his "cancer cure" business to Arkansas after being accused of quackery in Iowa, surrendered to the United States marshal on a federal indictment charging him with using the mails to defraud, according to the *Chicago Tribune* September 23. Baker was freed on a \$10,000 bond after his surrender. Five members of his staff who were indicted with him also gave up and were released on bonds of \$1,000 each. The indictments charge that the mails were used fraudulently in connection with a plan to obtain money for a cancer cure, it was stated. Baker is proprietor of the Baker Hospital at Eureka Springs. According to the report, members of the staff who surrendered with Baker are R. A. Bellows, hospital superintendent; Dr. Orville L. Beatty, Dr. William S. Hutto, Dr. Johnson L. Statler, and H. L. Fisher. For a number of years Baker ran a "sanatorium," radio station and a magazine and newspaper in Muscatine, Iowa. In June 1938 when his station had been closed following an injunction forbidding him to practice medicine without a license in Iowa he moved to Eureka Springs. In August 1937 he served a day in the Muscatine county jail and paid a \$1,000 fine on a charge of practicing medicine without a license. The federal radio commission closed Baker's KTNT station in the middle of a program, it was stated.

CALIFORNIA

Lectures on Pediatrics.—The Southwestern Pediatric Society sponsored its annual course of lectures and clinical discussions at Children's Hospital, Los Angeles, September 14-15. Dr. Joseph Brennemann, Chicago, was the lecturer. The subjects of his clinical discussions were "Pulmonary Conditions in Children," "Acute Abdominal Conditions in Children" and "The Subnormal Child and His Parents," according to the announcement.

New Public Relations Counsel.—Mr. Ross Marshall has been appointed press relations counsel to the California Medical Association and the following have been named to the committee on public health education: Drs. Frank R. Makinson, Oakland, chairman; Karl L. Schaupp, San Francisco, secretary; Samuel Ayres Jr., Los Angeles; Thomas A. Card, Riverside; Lowell S. Goin, Los Angeles; Junius B. Harris, Sacramento; Dewey R. Powell, Stockton, and Charles A. Dukes, Oakland, ex officio. The creation of this committee and its work was financed by a special assessment on members of the association authorized at the 1939 annual session.

New Psychiatric Service.—A separate psychiatric department was organized at the Mount Zion Hospital, San Francisco, by reorganizing the department of neuropsychiatry into two independent services—the neurologic service and the psychiatric service. Dr. Jacob Kasanin, director of the psychiatric department, Michael Reese Hospital, Chicago, and assistant professor of psychiatry, Rush Medical College, has been appointed chief of the service. Associated with him will be Dr. Mervyn Hirschfeld, assistant clinical professor of neurology, University of California Medical School. Dr. Joseph C. Solomon, formerly on the staff of the Baltimore Child Guidance Clinic, will direct the work in child psychiatry.

COLORADO

Personal.—Dr. Thomas D. Menser, La Junta, acting head of the Otero County health department, has been appointed director of the new city-county public health unit in El Paso County with headquarters in Colorado Springs.

Officers of State Medical Board.—At a recent meeting of the state board of medical examiners Dr. John Baron Farley, Pueblo, was elected president; Rodney Wren, D.O., Pueblo, vice president, and Dr. Harvey W. Snyder, Denver, reelected secretary.

CONNECTICUT

Hospital Association Joins State Medical Journal.—In January 1940 the journal of the state medical society will appear also as the official organ of the Connecticut Hospital Association. Mr. Sidney Davidson, administrator of Grace Hospital, New Haven, will represent the hospital association on the editorial board.

Commission to Study Physical and Mental Disabilities.—The governor has appointed a commission on the treatment and care of people of the state afflicted with physical or mental disabilities. Its members are Kenneth Wynne, Esq., New Haven, judge of the superior court; John A. Markham, Esq., Hartford, attorney; Dr. William H. Coon, Easton, the only physician member of the 1939 general assembly, which authorized the formation of the commission; Dr. Wilmar M. Allen, Hartford, superintendent of the Hartford Hospital, and Dr. Creighton Barker, New Haven, secretary of the state medical society. All problems, including expenditures, incident to the care of persons with mental or physical disabilities will be studied by the commission. According to the state medical journal, at the governor's request the commission will first concern itself with a study of the conditions and administration of the Norwich State Hospital for the Insane.

GEORGIA

Industrial Meeting.—The second annual meeting of the Georgia Industrial Surgeons Association will be held at The Cloister, Sea Island Beach, October 7. Included among the speakers will be Dr. Henry H. Kessler, Newark, N. J., on "Cineplastic Amputation."

Personal.—Dr. Malcolm M. Cook, Minneapolis, has been appointed director of laboratories at the Macon Hospital, effective September 1, succeeding the late Dr. Isadore J. Pass.—Dr. Clair A. Henderson, Dawson, has resigned as health officer of Terrell County to become assistant health commissioner of Savannah.

New Building for Academy of Medicine.—Plans are under way to construct a new home for the Academy of Medicine, Atlanta. It was voted to sell the present site of the society's home, 38 Prescott Street, N.E., to Dr. Luther C. Fischer for \$17,500. The society passed a motion unanimously requesting the directors of the Atlanta Academy of Medicine and Dentistry to liquidate the property and cancel the charter. The Medical Association of Georgia has moved its office from the academy to 105 Forrest Avenue.

Society News.—Dr. Jesse H. Campbell, Commerce, addressed the Jackson-Barrow County Medical Society, Jefferson, recently on diseases of the nose and throat.—Dr. Henry A. Seaman, Waycross, read a paper on "Treatment of Malig-

nancies of the Breast" before the Ware County Medical Society, Waycross, August 2.—The Fulton County Medical Society, Atlanta, was addressed September 21 by Dr. David Henry Poer on "Clinical Experiences with Use of Dihydrotachysterol (A. T. 10) in the Treatment of Ten Cases of Hypoparathyroidism." A symposium on malaria was presented before the society, Atlanta, September 7 by Drs. Charles Daniel Bowdoin, George M. Murray, Atlanta, and John W. Oden, Milledgeville.

ILLINOIS

Thirty-Five Deaths from Typhoid at State Hospital.—Thirty-five deaths have been reported in the outbreak of typhoid at the state hospital for the insane near Manteno, newspapers reported September 21. The epidemic has virtually halted for a second time construction of new buildings costing \$1,500,000 at the institution, it was stated.

Society News.—Dr. Archibald L. Hoyne, Chicago, discussed scarlet fever before the Kankakee County Medical Society September 14.—The Bureau County Medical Society was addressed in Princeton September 12 by Dr. Roger T. Vaughan, Chicago, on "Differential Diagnosis and Treatment of Acute Abdominal Lesions."—At a meeting of the Greene County Medical Society in Carrollton September 8 Drs. James E. Graham and William J. Morginson, Springfield, spoke on "The Orthopedic Aspects of the Foot" and "Fungus Infections of the Foot" respectively.

Chicago

Special Joint Meetings.—Dr. Soma Weiss, Hersey professor of the theory and practice of physic, Harvard Medical School, Boston, will lecture at a joint meeting of the Institute of Medicine of Chicago and the Chicago Society of Internal Medicine October 27 at the Palmer House. His subject will be "Syncope, Collapse and Shock—Mechanism and Treatment." Dr. Harry Gideon Wells, professor and chairman of the department of pathology, University of Chicago, will deliver the fourth Christian Fenger lecture of the institute and the Chicago Pathological Society on "A Neglected Subject, Adipose Tissue" at the Palmer House November 13.

INDIANA

Personal.—Dr. Harry E. Klepinger, Lafayette, has been appointed health commissioner of Tippecanoe County, succeeding the late Dr. Frank M. Biddle, Battle Ground.—Drs. Robert C. Speas and Edith M. B. Schuman have been named physicians for the student health service at Indiana University, Bloomington.—Mr. Paul R. Waddell has recently been appointed executive secretary of the St. Joseph County Medical Society. Mr. Waddell has worked as copywriter and account executive with advertising agencies in New York, Boston, Chicago and Pittsburgh, according to the state medical journal.

Pediatric Conference.—A postgraduate conference on pediatrics, sponsored by the Vanderburgh County Medical Society, was held in the Deaconess Hospital, Evansville, September 18. Among the speakers were Drs. Walter Russell Springstun on "Early Recognition of Rheumatic Fever"; Harold D. Lynch, "Common Feeding Problems of Infants and Children"; Dallas Fickas, "Early Recognition of Osteomyelitis"; Bernard D. Ravdin, "Diagnosis and Treatment of Acute Otitis Media in Children," and Charles F. Leich, "The Cross Eyed Child." Dr. Albert Graeme Mitchell, Cincinnati, addressed the banquet session on "Consequences of Diarrhea and What Can Be Done About Them."

IOWA

Society News.—At a meeting of the Des Moines Academy of Medicine and Polk County Medical Society September 26 the speakers were Drs. Walter D. Abbott on low back pain and Lee Forrest Hill, pleurodynia.—Dr. Temple S. Fay, Philadelphia, addressed the Linn County Medical Society, Cedar Rapids, September 29, on "Physical and Neurological Considerations of Interest to the General Practitioners."—Dr. Christian B. Luginbuhl, Des Moines, addressed the Hardin County Medical Society in Eldora recently on "Endocrine Therapy in General Practice."

Falls in the Home Outnumber Motor Accidents.—Falls in the home caused the deaths of more persons in Iowa during the first eleven months of 1938 than did motor vehicle accidents, according to the state department of health. For this period 462 deaths from falls were reported, as compared with 416 motor vehicle deaths. The greatest toll of lives claimed by injuries from falls was in the age group of 65 years and

older. In this group 405 deaths were recorded while motor vehicle accidents accounted for 106 deaths in this group and 188 deaths of persons between the ages of 25 and 64. Between 25 and 64 forty-two deaths from falls were reported; there were ten deaths of children under 5 years, three in the age group of 5 to 14 years and two between 15 and 24 years. Polished floors, icy porches and front steps, loose rugs and toys on the floor were given as causes of falls. Several children died from injuries sustained when they fell out of high chairs. Falling out of chairs, out of bed and tripping were among the causes of death of persons in the oldest age group. The most unusual death was that of a woman who walked out of the house in her sleep and fell into a well. She was rescued but died of injuries from the fall.

KENTUCKY

State Medical Election.—Dr. Austin Bell, Hopkinsville, was chosen president-elect of the Kentucky State Medical Association at the annual meeting in Bowling Green September 14, and Dr. John W. Scott, Lexington, was installed as president. Vice presidents elected were Drs. Arthur Clayton McCarty, Louisville; George H. Gregory, Versailles, and Eldon W. Stone, Bowling Green. The 1940 meeting will be in Lexington.

Changes in Health Officers.—Dr. George F. Brockman III, Louisville, has been appointed to succeed Dr. Neale M. Atkins as health officer of Muhlenberg County.—Dr. Price Sewell Jr., formerly of Jackson, has been appointed director of a new health unit in Owen County.—Dr. Gradie Rowntree, who has served as acting director of health of Louisville in the absence of Dr. Hugh R. Leavell during the past year, has now been appointed assistant to Dr. Leavell. Dr. James Robert Hendon will succeed Dr. Rowntree as director of activities in venereal disease control; Dr. Hendon has been acting director of this division.

MINNESOTA

University Medical School Observes Fiftieth Anniversary.—The University of Minnesota Medical School, Minneapolis, will celebrate its fiftieth anniversary October 12-14. The theme will be "Trends in Medical Progress with Particular Reference to Chemistry in Medicine." The program will include clinics, round table discussions and the following papers:

- Herbert Freundlich, Ph.D., The Colloid Chemistry of Membranes in Living Organisms.
- Dr. Maurice B. Visscher, The Performance of Osmotic Work in Living Systems.
- Dr. John P. Peters, New Haven, Conn., Some Reactions by Which Solutes May Be Differentially Concentrated by the Kidney.
- Lee I. Smith, Ph.D., Organic Chemistry in the Pursuit of Vitamin Research.
- George O. Burr, Ph.D., Investigations of Metabolism of the Fatty Acids.
- Dr. Charles H. Best, Toronto, Canada, Investigations Concerning the Problem of Thrombosis.
- Gov. Harold E. Stassen, Medicine and the Commonwealth.
- Guy Stanton Ford, Ph.D., president, University of Minnesota, The Place of Medicine in a University.
- Dr. A. J. Kluyver, professor of microbiology, Delft, Holland, Microbic Respiration.
- Dr. Robert G. Green, The Biology of Animal Virus Diseases.
- Dr. Perrin H. Long, Baltimore, Observations on the Mode of Action of Sulfanilamide and Its Derivatives.
- Dr. Henry F. Helmholz, Rochester, Minn., Chemistry in Urinary Antisepsis.
- Dr. Irvine McQuarrie, The Chemical Approach to the Problem of Convulsive Mechanisms.
- Dr. Herbert S. Gasser, New York, Methods of Analysis of Nervous Action.
- Detlev W. Bronk, Ph.D., Philadelphia, Nervous System in the Regulation of Visceral Processes.
- Dr. Harold S. Diehl, The Medical School of the University of Minnesota in Retrospect and Prospect.
- Dr. Donald C. Balfour, Rochester, Graduate Medical Education.
- Richard E. Scammon, LL.D., Progress in Medical Education on the American Scene.

Special lectures will include the university convocation address Thursday morning with Dr. Thomas Parran, Surgeon General, U. S. Public Health Service, Washington, D. C., as the speaker on "Medical Education, Research and the Public Health"; the first Elias Potter Lyon Lecture with Dr. Anton J. Carlson, Chicago, as the speaker on "The Role of the Fundamental Sciences in Medical Progress"; annual lecture of the Minnesota Pathological Society, Dr. George H. Whipple, Rochester, N. Y., "Production, Utilization and Significance of Blood Proteins"; the annual Alpha Omega Alpha lecture, Dr. Walter B. Cannon, Boston, "The Argument for Chemical Mediation of Nerve Impulses," and the Herman M. Johnson Lecture of the Minnesota State Medical Association, Dr. Olaf J. Hagen, Moorhead, class of 1906, on "The Medical School

from the Point of View of the Alumni." Dr. George A. Earl, St. Paul, president, state medical association, will present the distinguished service award of the state association posthumously to Dr. William J. Mayo, Dr. Charles H. Mayo, Rochester, and Dr. Herman M. Johnson, Dawson.

NEBRASKA

New Dean Appointed at Creighton.—Dr. Charles M. Wilhelmj, professor of physiology at Creighton University School of Medicine, Omaha, has been appointed full time dean to succeed Dr. Bryan M. Riley. Dr. Riley has served part time for the past six years but does not wish to devote full time, according to a newspaper announcement. He will remain on the faculty. Dr. Wilhelmj graduated from the St. Louis University School of Medicine, St. Louis, in 1922 and took the degree of master of science in 1923. After an internship he served as instructor in bacteriology and immunology at his alma mater and later on the staff of the Mayo Foundation, Rochester, Minn. The school is completing a two story addition, which will be used for the department of anatomy, additional examining rooms and laboratories.

NEW YORK

Graduate Lectures in Rochester.—The council committee on public health and education of the Medical Society of the State of New York has arranged a series of lectures for the Medical Society of the County of Monroe to be given in Rochester during October. The lectures are as follows:

- Dr. John D. Lytle, New York, Nephritis, October 2.
- Dr. Ferdinand J. Schoenck, Syracuse, New Factors Which Tend to Reduce Maternal Mortality, October 9.
- Dr. John F. Erdmann, New York, Gallbladder Disease, October 16.
- Dr. John J. Morton Jr., Rochester, subject not announced, October 23.
- Dr. Kenneth R. McAlpin, New York, A General Consideration of Anemia, Both Primary and Secondary, October 30.

District Meetings.—The annual meeting of the Fourth District Branch of the Medical Society of the State of New York was held in Ogdensburg September 19-20. Dr. John R. Schermerhorn, Schenectady, conducted a skin clinic and other speakers were Drs. Newell W. Philpott, Montreal, Canada, on "Breech Delivery"; Arthur R. Elvidge, Montreal, "Head Injuries"; Marvin Israel, Buffalo, "Physician's Responsibility in Child Behavior Problems," and Grant C. Madill, Ogdensburg, "Carcinoma of the Colon." At an evening session Dr. Terry M. Townsend, New York, president of the state society, made an address and Dr. Emerson Crosby Kelly, Albany, described "Greek Health Resorts in 500 B. C."—The Sixth District Branch met in Binghamton September 21 with the following speakers: Drs. Marjorie F. Murray, Cooperstown, on "Analysis of Abnormalities Disclosed by Routine School Health Examinations"; Carl Eggers, New York, "Carcinoma of the Gastrointestinal Tract," and Edward C. Reifenshein, Syracuse, "Digitalis: Its Use and Abuse."

New York City

Society News.—Dr. Meyer A. Rabinowitz will give the first of the fall series of Friday afternoon lectures of the Medical Society of the County of Kings, Brooklyn, October 6 on "Abdominal Diagnosis."—Dr. Edwin B. Bilchick addressed the Bronx Otolaryngological Society September 26 on "Affections of the Sphenoid Sinus."

OHIO

Society News.—Dr. Harold M. Crumley, Chillicothe, addressed the Highland County Medical Society, Hillsboro, August 4, on "Preparation and Postoperative Care of Surgical Patients."—Dr. Jerome Hartman, Dayton, addressed the Greene County Medical Society, Xenia, August 3 on "Diagnosis and Management of Disorders of the Feet."—Dr. Robert A. Moore, St. Louis, addressed the Richland County Medical Society, Mansfield, July 28 on "Clinical Use of Vitamin K and Treatment of Hemorrhagic Tendency in Jaundice."

Promotions at Western Reserve.—The following promotions in the faculty of Western Reserve University School of Medicine, Cleveland, have been announced, among others:

- Dr. Joseph M. Hayman Jr., to be professor of clinical medicine and therapeutics.
- Dr. Argyll J. Beams, associate clinical professor of medicine.
- William C. Barrett Jr., Ph.D., assistant professor of histology and embryology.
- Dr. William B. Wartman, assistant professor of pathology and pathologist at University Hospitals.
- Dr. Joseph L. Fetterman, assistant professor of nervous diseases.
- Dr. Otto L. Goehle, assistant clinical professor of pediatrics.
- Dr. Walter Heymann, assistant clinical professor of pediatrics.

Second Year of Lectures.—The Ohio State Medical Association began the second year of its five year series of post-graduate lectures with a session in Mansfield September 20 for one of the five regions into which the state has been divided. Lectures in the other regions began September 28. There are six sessions in each region, two lectures to each session. Subjects for this year's study are:

- Bleeding from the Uterus.
- What Shall We Do for the Pregnant Woman with Syphilis?
- Obstetrics in the Home.
- Acute Surgical Conditions in Childhood.
- Convulsions in Childhood.
- The Deformities of Poliomyelitis Must Be Prevented.
- The Importance of Routine Rectal Examinations.
- Helping the Public Reduce the Mortality of Acute Appendicitis.
- Protecting the Heart of the Patient with High Blood Pressure.
- How to Handle the Patient with Asthma.
- Hints to the General Practitioner in the Handling of Acute Eye Conditions.
- Present Day Viewpoints on the Diagnosis and Treatment of Cancer.

OKLAHOMA

County Society to Establish Clinic for Indigent.—The commissioners of Tulsa County voted August 14 to establish the Tulsa County Medical Clinic sponsored by the Tulsa County Medical Society to care for the county's indigent. Members of the society will staff the clinic, donating their services, and the county will furnish drugs. The county physician will serve as director; the position of county surgeon will be abolished and the head of the surgical department will serve without pay. The county will give the society \$300 a month for overhead expenses, including the salary of a case worker. Borderline patients must pay for their own medicines and hospitalization. Mr. Waite Phillips, Tulsa business man, agreed to contribute \$6,000 for equipment of the clinic, for which the Community Fund will contribute free rent and utilities in its building.

PENNSYLVANIA

District Meetings.—The annual meeting of the Third Councilor District of the Medical Society of the State of Pennsylvania was held at Skytop Lodge in the Pocono Mountains, Monroe County, September 7. Drs. David W. Thomas, Lock Haven, president of the state society, and Walter F. Donaldson, Pittsburgh, secretary, made addresses on "Medicine Faces Crisis" and "The National Scene" respectively. Dr. Edward L. Bortz, Philadelphia, chairman of the state society commission for the study of pneumonia control, spoke on modern treatment of pneumonia. Dr. Thomas and Dr. Bortz addressed the Second Councilor District Meeting at Swarthmore September 14, and other speakers were Drs. Belford C. Blaine, Pottsville, on "Diabetes Mortality in Pennsylvania"; Chauncey L. Palmer, Pittsburgh, "Public Assistance Medical Service in Review—Insurance Medical Service in Prospect," and Thomas Grier Miller, Philadelphia, "Observations on Small Intestinal Intubation."

Philadelphia

University News.—Dr. Franklin R. Miller, assistant professor of medicine, Western Reserve University School of Medicine, Cleveland, has been appointed assistant professor of medicine and assistant director of the department of hematology at Jefferson Medical College. Dr. Miller graduated from Harvard Medical School, Boston, in 1927.

Pittsburgh

Personal.—Dr. George L. Wessels, assistant superintendent of the Allegheny General Hospital, has been made acting superintendent since the death of Dr. G. Walter Zulauf.

Society News.—Speakers before the Allegheny County Medical Society, September 19, were Drs. William C. Hutchison, McKeesport, on "Tuberculin Testing of Students"; Morris A. Hershenson, "Cardiospasm"; Harry L. Baer and Harold R. Vogel, "Biophotometric Study of Vitamin A Deficiency in 250 Dermatologic Cases."

SOUTH DAKOTA

Health Officers to Meet.—The South Dakota Health Officers' Association will hold its annual meeting in Huron October 3. Dr. William F. Mengert, Iowa City, will be among the speakers, discussing maternal and child welfare. Others include Drs. Gerald J. Van Heuvelen, Pierre, state epidemiologist, on procedure in handling contagious disease, and Joseph C. Ohlmacher, Vermillion, on the state laboratory arrangements for making tests for syphilis under a recently enacted law.

UTAH

Community Hospital Dedicated at Provo.—The Utah Valley Hospital, a sixty bed institution built with the aid of the Commonwealth Fund as a part of its program for development of rural hospitals, was dedicated in Provo September 10. Patients were admitted September 18. The new hospital serves Utah County and parts of adjacent counties within a radius of 35 miles. The plant consists of the hospital proper and the nurses' residence, which will accommodate about twenty-five nurses. It represents an investment of more than \$300,000, of which about \$101,500 was contributed by the community and the remainder was a grant from the Commonwealth Fund. This is the Fund's tenth rural hospital. Dr. Fred R. Taylor, Provo, is chairman of the medical staff, to which all graduate and licensed physicians with established practices in the area are eligible. At the dedication exercises the speakers included Mayor Mark Anderson, of Provo; Mr. Clayton Jenkins, secretary and treasurer of the hospital; Dr. Melville H. Manson, New York, representing the Commonwealth Fund, and Heber J. Grant, Salt Lake City, president of the Latter Day Saints Church.

WISCONSIN

Lectures on Endocrinology at Milwaukee.—The Medical Society of Milwaukee County announces a postgraduate course in endocrinology, with the following speakers:

- Dr. Samuel Soskin, Chicago, Pituitary: The Master Gland, October 31.
- Dr. Jean Paul Pratt, Detroit, Female Endocrinology, November 7.
- Dr. Allan T. Kenyon, Chicago, Male Endocrinology, November 14.
- Dr. Edwin J. Kepler, Rochester, Minn., The Adrenal Gland, November 21.

District Meeting.—The Ninth Councilor District Medical Society held a meeting in Marshfield August 31. Guest speakers were Drs. Edward L. Tuohy and Peter S. Rudie, Duluth, Minn., on "Geriatrics in Its Relation to an Adequate Energy-Producing and Protective Diet" and "Postoperative Drainage in Appendicitis" respectively. Dr. Tuohy conducted a clinical pathologic conference in the afternoon assisted by Drs. George L. Berdez and John R. McNutt, Duluth.

GENERAL

Fellowships in Psychiatry Available.—A limited number of fellowships, provided by the Commonwealth Fund and other sources of training in extramural, especially child, psychiatry are available through the National Committee for Mental Hygiene. The committee will assign fellows for one or two years to selected child guidance clinics, the term and plan for each to be determined by his needs. Candidates should have had at least two years of psychiatry in an approved mental hospital in addition to qualities fitting them for extramural service. Questions and applications should be addressed to Dr. George S. Stevenson, National Committee for Mental Hygiene, Room 822, 50 West Fiftieth Street, New York.

Southern Tuberculosis Meeting.—The annual Southern Tuberculosis Conference will be held in Charleston, S. C., October 4-6 under the presidency of Dr. William Atmar Smith, Charleston. Medical and nonmedical sections will hold meetings Wednesday and Thursday and there will be two general sessions. Among the speakers at the general sessions will be:

- Dr. William B. Porter, Richmond, Va., Tuberculosis in the Medical Curriculum.
- Dr. Lewis J. Moorman, Oklahoma City, Tuberculosis in Nursing Curriculum.
- Dr. Horton Casparis, Nashville, Tenn., Present Status of Tuberculin.
- Dr. C. Howard Marcy, Pittsburgh, Report of the National Tuberculosis Association Committee on Tuberculosis Among Negroes.

At the conference banquet Wednesday evening the speakers will include Drs. Kendall Emerson, New York, managing director, National Tuberculosis Association, and Harry S. Mustard, professor of preventive medicine, New York University College of Medicine, New York.

Southern Psychiatrists to Meet.—The annual meeting of the Southern Psychiatric Association will be held in Louisville, Ky., at the Brown Hotel October 9-10 under the presidency of Dr. Charles S. Holbrook, New Orleans. Among the speakers will be:

- Dr. John W. Scott, Lexington, Ky., An Internist's Reaction to the Psychoneuroses.
- Dr. Oscar O. Miller, Louisville, Psychiatric Medicine.
- Dr. Arthur H. Ruggles, Providence, R. I., Recent Advances in Psychiatry.
- Dr. Lydia G. Giberson, New York, Psychiatry and Insurance.
- Dr. Emerson A. North, Cincinnati, Psychopathic Personalities.
- Dr. Leon J. Saul, Chicago, Cerebral Manifestations Observed in the Neuroses.
- Dr. Thomas Douglas Noble and Frederick G. Germuth, Sc.D., Towson, Md., Barbiturates, Physiologic Reactions.
- Dr. Harry Stack Sullivan, New York, Psychiatrists and National Defense.
- Dr. George S. Sprague, White Plains, N. Y., Some Implications of the Psychotic State.

Where Infant Mortality Has Declined.—A study of the principal causes of death in infants under 1 year old during the period 1917 to 1937 was recently published by the Metropolitan Life Insurance Company in the *Statistical Bulletin*. Diarrhea and enteritis was the leading cause of infant deaths in 1917, with a toll of 20 deaths per thousand live births, or 21 per cent of all deaths under 1 year. In 1937 only 4.1 deaths per thousand live births were from this cause. The mortality rate from premature birth was 19.1 in 1917, reached a peak of 20.2 in 1918 and by 1937 had fallen to 15.4, still outranking any other cause of death in infancy. Congenital debility was at a high point of 9.2 deaths per thousand live births in 1918 and dropped to 3.5 in 1937. Congenital malformation has been only slightly influenced by antepartum care, a chart showed. Injury at birth, which rose sharply between 1918 and 1931, has now declined noticeably, the study showed. Of the respiratory infections, bronchitis and bronchopneumonia have declined most rapidly; the peak rate of 11.1 per thousand live births in 1918 had declined to 5.6. Influenza and pneumonia have shown some improvement since 1931. Tuberculosis and diphtheria have shown notable declines, mortality from both being at one fifth of the 1917 levels.

National Safety Congress.—The twenty-eighth annual session of the National Safety Congress will be held at Atlantic City October 16-20. There will be many addresses of medical interest. One session will be devoted to "Occupational Disease Control" with the following participants: Roy S. Bonsib, chief safety inspector, Standard Oil Company of New Jersey, New York; Warren A. Cook, Zurich General Accident and Liability Insurance Company, Chicago; Dr. Arthur G. Cranch, Union Carbide and Carbon Corporation, New York; Philip Drinker, C.E., professor of industrial hygiene, Harvard School of Public Health, Boston; Dr. Leonard Greenburg, New York State Department of Labor, New York, and Willis G. Hazard, Owens-Illinois Glass Company, Toledo, Ohio. Among individual papers will be:

- Dr. Albert E. Russell, U. S. Public Health Service, Chicago, Syphilis Control and Its Relation to the Food Industry.
- Dr. Oscar A. Sander, Milwaukee, Metal Fume Poisoning.
- Drs. Joseph V. Klauder, Philadelphia, and Elmer R. Gross, Wilmington, Del., Dermatitis Control—Proper and Improper Use of Cleansing Agents; Soap and Other Detergents.
- Dr. Louis H. Frechtling, Hamilton, Ohio, Industrial Hernia and Its Control.
- Dr. James W. Long, Port Arthur, Texas, Medical Services in the Petroleum Industry.

Dr. Victor G. Heiser, New York, will speak at a luncheon of the section on industrial nursing on "Improving the Health of Industrial Workers," and Dr. Howard W. Haggard, New Haven, Conn., at a dinner of the New Jersey chapter, American Society of Safety Engineers and the engineering section, on "Poisonous Gases of Modern Industry."

FOREIGN

Contributions Requested in Honor of Dr. Schaumann.—In honor of Dr. Jörgen N. Schaumann, chief physician of the St. Görans Finsen Institute, Stockholm, Sweden, who celebrates his sixtieth birthday this year, a group of his friends and colleagues propose a jubilee number of *Acta medica Scandinavica*, with extracts from *Acta dermato-venereologica*. Twenty-five years has passed since Schaumann first submitted the work in which he showed that lupus pernio (Besnier) and Boeck's sarcoids were skin manifestations of a generalized disease which he called lymphogranuloma benignum or lymphogranulomatosis benigna. Owing to differences of opinion as to the suitability of this name, it was suggested in 1935 that the disease be called Schaumann's disease. Those who wish to contribute articles to the volume to honor Dr. Schaumann are requested to send their contributions to the editor of *Acta medica Scandinavica*, Prof. Israel F. Holmgren, Jacob Westinsgatan 4, Stockholm, before November 15.

Government Services

Examination for Navy Medical Corps

An examination for commission and for appointment as intern in the Medical Corps of the United States Navy will be held at all naval hospitals in the United States and at the Naval Medical School, Washington, D. C., beginning November 6. Candidates must be between the ages of 21 and 32 at the time of appointment and graduates of or senior medical students in recognized medical schools. Those interested should write the Surgeon General, U. S. Navy, Bureau of Medicine and Surgery, Navy Department, Washington, for further information.

The Annual Meeting of the British Association for the Advancement of Science

The imminence of war did not prevent the annual meeting of the British Association for the Advancement of Science, which was held at Cardiff.

A NEW APPROACH TO BIOLOGY

In his presidential address to the Section of Chemistry Prof. E. K. Rideal said that whereas toward the end of the last century the biologist was concentrating on the whole living unit of the cell, in this century the tendency has been for the study of the living unit to be dropped and in its place investigations to be made on particular processes such as oxidation and reduction. This change of approach, though it has produced many valuable results, inevitably leaves out of account the coordination of the separate activities of cells or cell assemblages. One of the chief characteristics of living matter is the presence both of material and of energy in the shape of films, membranes, fibrils and fine capillaries—a microstructure with a relatively huge surface. To do justice to this feature of life we need to study the properties of what biologists call interphases—the surfaces of separation between bulk phases of substance. We want to know more of the properties of "matter in the boundary state."

An analysis of the colloidal properties of living matter reveals that a large part of the material and energy lies in the interphase. The question arises: How far are physical and chemical reactions modified? The composition and structure of the interphase have been exhaustively examined in the last twenty years. Recent work has shown that the interphase often consists of what is called monolayer, a sheet of molecules only one layer thick. Much work has been done on the physical properties of the monolayers of the macromolecules such as protein and methylated cellulose and starches. These are of interest in that two dimensional gels, prototypes of membranes, can be formed. The fact that the molecules in monolayers are orientated in respect both to the substrate and to their neighbors and that the orientation can be affected by contraction or expansion of the monolayer has an important bearing on the reactions. Surface chemical reactions, including both enzyme activity and photochemical processes, are examples.

Since molecules at interfaces are orientated, molecules in the two component systems of different species can be adlinedated with respect to one another. Complexes are formed by the penetration of a monolayer of one species by the molecules of the penetrant. These penetrative reactions appear to be involved in various biologic processes, such as lysis, agglutination and sensitization, and to play a part in the actions of various drugs.

Study of the properties of the interphase surface is throwing light on many biologic facts. It enables a theoretical interpretation to be given of the existence of bio-electrical potentials. The cancer producing hydrocarbons, examined by the monolayer technic, prove to be unreactive themselves but readily converted into extremely active and water soluble substances which are strongly lethal to paramecium, apparently because of the ease with which they attack protein monolayers. These monolayer studies may throw light on the cancer problem, as interphase studies are necessary for the construction of any model, however crude, of the mechanism of biologic organization and function.

PERSPECTIVES IN EVOLUTION

In the Section of Zoology the president, Prof. James Ritchie, devoted his address to perspectives in evolution. He said that investigation of the properties of living things has led to a modification of both the extremely mechanistic and the extremely vitalistic views of life and has gone far to reducing its mystery to terms of physics and chemistry. Theories of the cell as an electromagnetic unit of life and of life as a dynamic equilibrium between such units, or of life and the cell as originating in an ethereal vortex, are less convincing than the researches which show that certain activities of cells conform to the laws of osmotic systems, to Donnan's membrane equilibrium and to catalytic action brought about by enzymes. But none of these interpretations reach the ultimate secret of life. This is apparent in a perspective of evolutionary processes.

Living organisms have aggregated vast deposits of calcareous and silicious ooze from the dilute solutions of the ocean and have gathered great formation of coal from the tenuous stores of carbon dioxide in the atmosphere. This is something quite different from the normal progress of gases or solutions to maximum dispersal of their particles. Moreover, the evolution of life from the simple to the complex is an increase of orderly arrangement, apparently opposed to the thermodynamic law of increasing randomness. Living matter appears to hold up the physical course of the degradation of matter, if it does not actually reverse it, through its power of trading with the environment, so that it can build up stores of high potential energy from materials of lower potential.

Another recent development is the lengthening of perspective life on the earth. Newer knowledge of the ages of geological formation, based on the break up of radioactive minerals in the rocks, shows the extreme slowness of evolution and emphasizes the significance of man as an agent of change in the living world, for his active part in this process is virtually confined to our era and mainly to the last 300 years. In that insignificant period man has produced faunal changes in civilized lands comparable only to the great secular changes of world evolution.

The 1,200 million years through which life has been evolving lead to a view of man's future. His past is insignificant in time; his long future is unknowable as far as science is concerned. But bearing in mind the impetus of evolution, we can conclude that his progress will be continued toward perfection of social life and widening of the social idea to include nations as well as individuals. The history of life on the earth is opposed to the view that with the coming of man evolution would cease or be tied up for all time to trifling changes in brain power or better social organization. It suggests that man, so far the greatest manifestation of life on the earth, may be no more than a stage on the path of evolution to a greater future.

The Indian Journal of Surgery

The *Indian Journal of Surgery* is a new periodical published as an organ of the Association of the Surgeons of India. The opening editorial complains that the Indian practitioners "have been completely under the thumb of the Indian Medical Service" until quite recently and even now are not completely emancipated. While giving this great service credit for much original research, the writer does not mention that it introduced European medicine into India and that its many distinguished members created the greater part of tropical medicine. It is thanks to this service and the British government, whose instrument it is, that Indians have been educated in modern medicine.

The first number, of forty-eight pages, is devoted to the inaugural conference of the Association of Surgeons of India. In his presidential address Lieut.-Col. Gopinath Pandalai, F.R.C.S., of the Indian Medical Service, stated that the association had received the good wishes of the Association of the Surgeons of Great Britain and Ireland and that when he

visited Rochester the Mayos asked him to convey their cordial greetings. Only two subjects are reported from the conference—the treatment of ileocecal tuberculosis and carcinoma of the tongue. While showing nothing of original importance, the papers and discussions are quite up to the European level. This was to be expected, as several of the surgeons hold the highest qualification—the fellowship of the Royal College of Surgeons of England. The position attained by the Indian surgeons today is only one result of the British policy of elevating the peoples of the empire to the level at which they can rule themselves. Nothing comparable has ever been done by any other empire, ancient or modern.

BERLIN

(From Our Regular Correspondent)

Aug. 17, 1939.

Public Health in 1938

In the report of the public health service is information regarding public welfare. This information does not include lands acquired recently by conquest. Of those intending to marry, 47 per cent made use of public consultations (36 per cent in 1937). Of these, 38 per cent received a marital loan, that is to say an addition to the expenses incidental to getting established. Maternity advice was sought by 6 per cent of pregnant women. Infant welfare stations were available to the public in the ratio of one for seventy-seven infants born and were actually consulted on the average by sixty mothers per station. Consultation for preschool children was offered in the proportion of 718 per hundred thousand inhabitants. More than 3,000,000 children of school age received attention, that is, about 4,545 per hundred thousand inhabitants. The schools of almost all districts, with few exceptions, were furnished dental supervision.

The care of tuberculous patients was extended during 1938. About 1,500,000 patients, against 1,250,000 in 1937, received attention. The number of roentgen treatments rose from about 1,250,000 to about 1,750,000. Hospitalization in public institutions increased from 45,000 to 49,000. Average x-ray examinations were 100 to thirteen patients. Somewhat greater facilities were provided for the treatment of venereal diseases, but the number of individual cases decreased (192,000 in 1938 against 200,000 in 1937). Consultation stations for cripples were increased and, on the average, 242 persons were advised per hundred thousand inhabitants. The increase in stations for alcoholic persons is more than counterbalanced by the decrease of the individuals consulting. However, other agencies not identical with these cooperated in the care for alcoholic patients and their reports are not included in these figures. About 107,000 persons with psychic troubles were advised against 91,000 in 1937. The care for the infirm and aged is likewise organized according to regions. These facts should not be regarded as completely evaluating the achievements of public health welfare, because there are other agencies besides the official health stations connected with public health bureaus. At any rate, the facts presented give sufficient insight into the extensive nature of public welfare activities in operation in Germany.

Primary Infection with Tuberculosis in the Army

Dr. Hans Mayer has published the results of his investigations in the *Deutscher Militärarzt*. In the time between graduation from school (about 14 years) and military service (about 20 years of age) there is a huge gap in our knowledge of the tuberculin reaction. According to the literature, almost uniform results have been obtained from serial tuberculin inoculations in different European armies. From 15 to 20 per cent of those reporting for military training are free from tuberculosis. Mayer examined 600 soldiers in 1937, employing the Pirquet-Mantoux test, and obtained 84.33 per cent of positive reactions. No noteworthy difference was found between city, town and

country recruits. Most of the 600 were natives of southern or southwestern Germany. With radiologic examination, seventy-eight showed a specific condition with positive reaction; sixty-seven (11.67 per cent) had a calcified primary complex. One must also consider that many of the recruits with negative reactions are increasingly susceptible, because of lack of previous exposure, and acquire primary infection during training. In most cases this infection does not lead to illness. The change from negative to positive reaction remains the only symptom. By means of careful selection of recruits for training and early recognition of the tuberculous, the army can be well protected against tuberculosis.

Epidemic Poliomyelitis in Frankfort on the Main

Dr. Windorfer has published his observations in the children's clinic of the university in Frankfort on the Main regarding 150 patients treated for this disease last year. The infection of infants, the higher mortality rate with increasing age and the greater prevalence among boys and girls (eighty-eight against sixty-two) were all typical. Ten of the 150 patients died, fifty-four had paralysis eight weeks after, and fifty-seven had recovered at the time of discharge from clinical care. In twenty-nine no paralysis had appeared at all. The treatment employed consisted (1) in the use of serum, (2) in the administration of vitamin B₁ and (3) complete rest. Forty children were treated with serums, 110 without. Comparison of results favored neither therapy. Six patients were given serum pre-paralytically; four of these remained free from paralysis, one acquired serious paralyzes of a permanent nature and one died. Thirty-five patients were given ten injections of vitamin B₁ of 10 mg. each. In fifteen a gradual improvement set in, in nine a good involution, and in the other eleven no involution. No decisive effect of vitamin B₁, subcutaneously administered, can therefore be deduced. In lumbar punctures of fifteen patients with Landry's paralysis, observations gave the impression that vitamin B₁ resisted the advance of fatal paralyzes. However, the final results (three deaths, ten serious paralyzes of a permanent nature and two recoveries) constitute no evidence for a specific effect of vitamin B₁. For those acutely ill, complete rest was the best treatment.

Congress of Otorhinolaryngologists

In this year's meeting of the Congress of Otorhinolaryngologists in Vienna the two main topics were lupus and tumors of the acusticus. Prof. Alfred Stühmer of Freiburg, a pioneer in the systematic treatment of lupus, read the dermatologic paper. The main difficulty, he said, lay in applying the treatments at the right time and in the early stage of the disease. Statistics for the nation indicate 30,000 cases of lupus and clearly show that cases are reported only as individual districts possess good organizations. The important thing in treating patients was to continue therapeutic measures systematically until a complete cure had been effected. Much harm is done through incomplete measures. Lupus is only one form of cutaneous tuberculosis, though the most frequent. The organism possesses a certain resistance to each of these forms; for this reason mutation of one of these phenomena into another is rare.

Prof. Alfred Brüggemann of Giessen, an otorhinolaryngologist, stated that transitions into other forms of mucous membrane tuberculosis were quite common and that benign lesions often showed transition to those prognostically less favorable. It was not rare for a lupus carcinoma to bring about a slow and painful death. Prof. Johannes Zange of Jena pointed out that, contrary to former belief, such patients could be operated on. Radical surgical intervention could effect cures even in advanced destruction of the facial tissue and accessory nasal cavities. N. G. Riecke of Kiel discussed periarteritis nodosa of the mucosa of the nose from the point of view of differential

diagnosis. It begins with a simple cold and induces death within a few months by rapid destruction of cartilage and bone and the formation of slightly hemorrhagic granulations. Clinical observations in Münster during fourteen years proved the efficacy of roentgen rays with a dosage of 70 mg. to 1 mm. of zinc filtration per square centimeter in contact irradiation. He also called attention to the great curative value of vitamin C in treating tuberculous mucous centers.

L. Schönbauer, Viennese surgeon, treated the question of the surgical therapy of tumors of the acousticus. In fifty-six cases postoperative mortality amounted to 25 per cent; recovery, after three years, to 28 per cent. The surgeon, he said, gets access to the tumor by opening as broad as possible a path to the occipital cranial fossa. Güttich of Cologne stated that the results obtained by otologists corresponded to those mentioned. Otologists had two advantages in the surgery of these tumors, to proceed altogether or partially by way of the labyrinth or to utilize the experience gained in operating within narrow confines and thus to reduce the great danger of injury to the brain through displacement of the cerebellum.

Meeting of Balneologists

The meeting of the German society of balneologists and climatologists, with the inclusion of Austria and its alpine regions, is to make intensive studies of the curative possibilities of mountain altitudes. As Professor von Ficker of Vienna explained, climatologic values must be judged not only by solar radiation, which included warmth effects and solar wavelengths, but also by the humidity of the air, the winds and the oxygen content of alpine altitudes. Localities especially suitable for mountain resorts and sanatoriums are those possessing a high degree of dry air, though with somewhat higher temperature, and are found 300 meters above valley level even if the valley is foggy. Such air is favorable to tuberculous persons, whereas the healthy tourist seeking relaxation can utilize the strong stimulation of climate changes, passing from cool valleys to warmer and drier altitudes frequently within an hour.

The second chief topic concerned the comparison between natural medicaments and their artificial substitutes. Artificial climate produced in rooms does not constitute a sufficient substitute for the natural climate. Climatizing is valuable for operating rooms and in certain diseases but not for general application to hospitals and workshops. Quantitative differences were found in artificial products recommended for drinking treatments instead of natural waters; likewise the total absence of the effect was noted. In some cases an opposite effect was produced. Among the 900 artificial bath preparations examined, a few good ones were discovered among a host of inferior ones.

Marriages

ARTHUR J. VANDERGRIND, Assistant Surgeon Lieutenant, U. S. Navy, to Miss Pearl Mac Arington of Urial, Ala., in Dahne, May 25.

ALBERT E. AUSTIN, Old Greenwich, Conn., to Miss Lillian V. Lounsbury of Stamford, Conn., in Norfolk, Mass., September 3.

HJALMAR MORTENSBAK, Hanska, Minn., to Miss Muriel Swihart of Balaton in St. Paul, June 3.

MOLLEURUS COUPERUS, Chehalis, Wash., to Miss Florence Schmidt of Dickinson, N. D., July 19.

LOUIS FRANK LESSER, Mountain Home, Idaho, to Miss Mary Wolf of Delaware, Ohio, June 21.

HERMAN H. SCHOFFMAN, Seattle, to DR. LILY LEDERER of Vienna, Austria, June 22.

ROBERT H. WARD to Miss Nancy Stark, both of New York, June 24.

HUNTER J. MACKAY to Miss Leola Trotter, both of Seattle, June 24.

Deaths

John Alexander Donovan ☉ Butte, Mont.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1894; member of the American Academy of Ophthalmology and Otolaryngology and the Pacific Coast Oto-Ophthalmological Society; fellow of the American College of Surgeons; chairman of the Section on Ophthalmology of the American Medical Association, 1926-1927; past president of the Medical Association of Montana; member of the state board of medical examiners; chairman of the medical advisory board and member of the state board of National Defense during the World War; on the staff of St. James Hospital; aged 67; died, July 21, of mesenteric thrombosis.

Clarendon James Combs ☉ Oshkosh, Wis.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1898; fellow of the American College of Surgeons; served during the World War; retired in 1938 as commanding officer of the 370th medical regiment of the U. S. Reserve Officers Training Corps; aged 64; on the staffs of St. Mary's Hospital and the Mercy Hospital, where he died, July 19, of gallstones, acute hemorrhagic pancreatitis and myocarditis.

William Mortimer Brown, Rochester, N. Y.; University of the City of New York Medical Department, 1889; fellow of the American College of Surgeons; formerly on the staff of the Rochester General Hospital; past president of the Monroe County Medical Society; consultant in obstetrics and gynecology at the University of Rochester School of Medicine; aged 71; died, July 25, of illuminating gas poisoning, self administered.

Frederick Martin Bauer, Whitesboro, N. Y.; University of the City of New York Medical Department, 1886; member of the Medical Society of the State of New York; formerly medical superintendent in charge of the Tuberculosis Division, Metropolitan Hospital, Blackwell's Island, and deputy medical superintendent of the Kings County Hospital, Brooklyn; aged 79; died, July 4, of coronary thrombosis and arteriosclerosis.

William Arthur Toland, Houston, Texas; Jefferson Medical College of Philadelphia, 1911; member of the State Medical Association of Texas; fellow of the American College of Surgeons; served during the World War; on the staff of the Memorial Hospital; on the visiting staffs of St. Joseph's Infirmary, Methodist, Hermann and Houston Negro hospitals; aged 56; died, July 23.

Robert John McGuire ☉ Syracuse, N. Y.; Syracuse University College of Medicine, 1912; fellow of the American College of Surgeons; instructor of gynecology at his alma mater; on the staff of the Hospital of the Good Shepherd; served during the World War; aged 54; died, July 23, of coronary occlusion, chronic myocarditis and arteriosclerosis.

Edward Michael Dooley, Buffalo; Niagara University Medical Department, Buffalo, 1890; member of the Medical Society of the State of New York; on the staffs of the Emergency Hospital of the Sisters of Charity and the Mercy Hospital; aged 78; died, July 20, of diabetes mellitus, peritonsillar abscess, arteriosclerosis and chronic myocarditis.

Charles Walker Streamer ☉ Pueblo, Colo.; University of Colorado School of Medicine, Denver, 1916; past president of the Pueblo County Medical Society; served during the World War; fellow of the American College of Surgeons; aged 46; on the staffs of the Parkview Hospital and St. Mary's Hospital, where he died, July 5, of bronchopneumonia.

Frank Henry Carlisle ☉ Wellesley, Mass.; Harvard University Medical School, Boston, 1904; member of the American Psychiatric Association and the New England Society of Psychiatry; formerly medical director of the Bridgewater (Mass.) State Hospital; aged 59; died, July 20, in the Palmer Memorial Hospital, Boston, of carcinoma of the colon.

Alexander MacGillivray Young, Saskatoon, Sask., Canada; McGill University Faculty of Medicine, Montreal, Que., 1906; at one time mayor; formerly registrar Council of the College of Physicians and Surgeons of Saskatchewan and secretary of the Saskatchewan Medical Association; aged 60; died July 9, of brain tumor.

Henry Augustus Peters ☉ Oconomowoc, Wis.; Milwaukee Medical College, 1906; past president of the Waukesha County Medical Society; for many years member of the state board of pharmacy examiners; aged 66; on the staff of the Summit Hospital, where he died, July 19, of pulmonary embolism following an appendectomy.

Abraham Orenstein, New York; Long Island College Hospital, Brooklyn, 1910; member of the Medical Society of the State of New York; served during the World War; on the

staffs of the New York Polyclinic Hospital and the Veterans Administration Facility; aged 51; died, July 13, of arteriosclerosis and hemiplegia.

David Fitch Armstrong, Auburn, N. Y.; College of Physicians and Surgeons, Medical Department of Columbia College, New York, 1895; member of the Medical Society of the State of New York; formerly on the staff of the Auburn City Hospital; aged 70; died, July 31, of cerebral hemorrhage.

Vincent Joseph Irwin, Springfield, Mass.; University of Vermont College of Medicine, Burlington, 1896; member of the Massachusetts Medical Society; member of the American Academy of Ophthalmology and Otolaryngology; aged 81; died, June 19, in Tampa, Fla., of chronic nephritis and arteriosclerosis.

Charles W. Polk, Memphis, Tenn.; Memphis Hospital Medical College, 1902; member of the Tennessee State Medical Association; formerly in charge of child hygiene work for the board of health of Shelby County, and health officer of Lauderdale County; aged 59; died, July 5, of cerebral thrombosis.

Charles Floyd Stafford, Cle Elum, Wash.; Northwestern University Medical School, Chicago, 1913; member of the Washington State Medical Association; at various times city and county health officer; aged 52; died, July 6, in the Swedish Hospital, Seattle, of staphylococcal septicemia.

James Egbert McClelland Roberts, Charleston, W. Va.; University of Louisville (Ky.) School of Medicine, 1925; member of the West Virginia State Medical Association; on the staff of the Mountain State Hospital; formerly county coroner; aged 40; died, July 25, in Colliertown, Va.

Arthur Henry Miller, Denver; University of Colorado School of Medicine, Denver, 1923; member of the Colorado State Medical Society; on the staffs of the Denver General, Children's, Presbyterian, St. Luke's and Porter hospitals; aged 56; died, July 25, of coronary thrombosis.

Peter H. Stockfleth, Cameron, Mo.; Eclectic Medical Institute, Cincinnati, 1905; Barnes Medical College, St. Louis, 1906; served during the World War; formerly on the staff of the Western Oklahoma Hospital, Supply; aged 59; died, July 5, of a self-inflicted bullet wound.

Harry C. Tull, Salisbury, Md.; University of Maryland School of Medicine, Baltimore, 1900; member of the Medical and Chirurgical Faculty of Maryland; on the staff of the Peninsula General Hospital; aged 65; died, July 17, in Ocean City of coronary thrombosis.

Howard Birch Pedigo, Beaumont, Texas; Tulane University of Louisiana School of Medicine, New Orleans, 1902; served during the World War; on the staffs of the Hotel Dieu Hospital and St. Therese Hospital; aged 61; died, in July, of a self-inflicted bullet wound.

G. Thomas Lee Bryan, Abilene, Texas; American Medical College, St. Louis, 1908; member of the State Medical Association of Texas; veteran of the Spanish-American War; aged 62; died, July 28, in the Veterans Administration Facility, Waco, of cerebral arteriosclerosis.

Adalbert Jerome Cole, Clear Lake, Iowa; Rush Medical College, Chicago, 1883; member of the Iowa State Medical Society; formerly mayor of Britt, councilman and member of the school board; aged 86; died, July 17, in Mason City of arteriosclerotic nephritis.

William Charles Porath, Storm Lake, Iowa; Hahnemann Medical College and Hospital, Chicago, 1902; Denver and Gross College of Medicine, 1903; president of the Buena Vista County Medical Society; aged 66; died, July 18, of coronary occlusion.

Henry Fletcher Long, Statesville, N. C.; University of Maryland School of Medicine, Baltimore, 1892; fellow of the American College of Surgeons; surgeon to a hospital bearing his name; aged 70; died, July 28, of hypostatic pneumonia and erysipelas.

James Bryant Person, Selma, N. C.; Medical College of Virginia, Richmond, 1897; member of the Medical Society of the State of North Carolina; past president of the Johnston County Medical Society; aged 65; died, July 16, of lymphosarcoma.

Walter Landor Savage, Buffalo; Niagara University Medical Department, Buffalo, 1897; veteran of the Spanish-American War; formerly on the staff of the U. S. Marine Hospital; died, July 24, of chronic myocarditis and arteriosclerosis.

James Charles Sharkey, Rensselaer, N. Y.; Albany Medical College, 1896; school physician; formerly county coroner and

health officer of Rensselaer; on the staff of St. Peters Hospital; aged 70; died, July 5, of cerebral thrombosis and arteriosclerosis.

Richard Stephen MacCabe, Oklahoma City; University of Missouri School of Medicine, Columbia, 1906; member of the Oklahoma State Medical Association; on the staff of St. Anthony Hospital; aged 56; died in July of rheumatic heart disease.

Harry Wolf Nye, Osborne, Kan.; College of Physicians and Surgeons, Keokuk, Iowa, 1895; Drake University Medical Department, Des Moines, Iowa, 1897; member of the Kansas Medical Society; aged 66; died, July 6, of nephritis and myocarditis.

Arthur Heath Flickwir, Fort Worth, Texas; University of Pennsylvania Department of Medicine, Philadelphia, 1901; health officer of Houston, 1920-1929; for many years director of public health and welfare of Fort Worth; aged 60; died, July 26.

Joseph Matthew Griffith, Tyler, Texas; Baylor University College of Medicine, Dallas, 1918; formerly secretary of the Smith County Medical Society; on the staff of the Mother Frances Hospital; aged 49; died, July 28, in Midland.

Lea Hume, Eagle Pass, Texas; University of Texas School of Medicine, Galveston, 1902; acting assistant surgeon, U. S. Public Health Service; aged 63; died, July 27, of injuries received when the horse he was riding was struck by a truck.

Joseph Edwin Slicer, Shreveport, La.; Tulane University of Louisiana School of Medicine, New Orleans, 1901; member of the Louisiana State Medical Society; served during the World War; aged 59; died, July 15, of cerebral hemorrhage.

Arthur Burke O'Brien, Rochester, N. Y.; University of Buffalo School of Medicine, 1921; on the staff of St. Mary's Hospital; aged 43; died, July 6, of injuries received when the automobile in which he was driving was struck by a train.

Ernest Lawrence Perri, Monaca, Pa.; Jefferson Medical College of Philadelphia, 1921; physician for the board of health of Monaca and school board; on the staff of the Rochester (Pa.) General Hospital; aged 41; died, July 9.

Charles Edward Thompson, De Funiak Springs, Fla.; Faculty of Medicine of Trinity College, Toronto, Ont., Canada, 1886; L.R.C.P., Ireland, 1886; aged 80; died, July 21, in a hospital at Pensacola of carcinoma of the prostate.

Philippe Auguste Charette, Montreal, Que., Canada; School of Medicine and Surgery of Montreal, Faculty of Medicine of the University of Laval at Montreal, 1917; served during the World War; aged 46; died, July 14.

John H. Hereford, Colorado Springs, Colo.; St. Joseph (Mo.) Hospital Medical College, 1882; member of the Colorado State Medical Society; on the staff of the Beth-El Hospital; aged 77; died, July 27, of cerebral hemorrhage.

Frederick Fulton Tucker, Nacogdoches, Texas; Tulane University of Louisiana School of Medicine, New Orleans, 1924; on the staff of the City Memorial Hospital; aged 39; died, July 29, of a self-inflicted bullet wound.

Levings A. Opdyke, Jersey City, N. J.; New York Homeopathic Medical College, 1885; member of the Medical Society of New Jersey; aged 77; died, July 6, of chronic endocarditis and a fractured hip received in a fall.

Henry Joy Francis, Troy, Ohio; Ohio State University College of Medicine, Columbus, 1939; aged 24; intern at St. Elizabeth Hospital, Dayton; was found dead, July 4, of incised wounds of the wrists, self inflicted.

James Oscar Ristine, Maquoketa, Iowa; State University of Iowa College of Medicine, Iowa, 1896; member of the Iowa State Medical Society; aged 73; died, July 14, in St. Luke's Hospital, Davenport, of acute nephritis.

Willis Edwards Lowry Sr., Laredo, Texas; College of Physicians and Surgeons, Baltimore, 1892; member of the State Medical Association of Texas; aged 69; died, July 29, in the Santa Rosa Infirmary, San Antonio.

Hugh Gilmer Welpton, Des Moines, Iowa; Drake University Medical Department, Des Moines, 1897; formerly a medical missionary; aged 68; died, July 3, in the Baylor University Hospital, Dallas, Texas.

Robert L. Cox, Houston, Texas; Tulane University of Louisiana School of Medicine, New Orleans, 1899; aged 63; on the staff of the Memorial Hospital, where he died, July 9, of carcinoma of the pancreas.

Wayne Paul O'Brien, Hot Springs, S. D.; University of Illinois College of Medicine, Chicago, 1911; aged 50; on the staff of the Veterans Administration Facility, where he died, July 25, of angina pectoris.

Louis Reich, Newark, N. J.; Medico-Chirurgical College of Philadelphia, 1906; veteran of the Spanish-American War; on the staff of the Beth Israel Hospital; aged 58; died, July 13, of cerebral hemorrhage.

Wilbur Fisk Thomson, Houston, Texas; University of Arkansas School of Medicine, Little Rock, 1938; on the staff of the Wright Clinic and Hospital; aged 27; was drowned, July 30, at Galveston.

John W. Leininger * Gladwin, Mich.; Western University Faculty of Medicine, London, Ont., Canada, 1891; formerly mayor and president of the school board; aged 82; died, July 9, of chronic thrombosis.

Clarence Lee Crawford Atkeson, Columbia, Ala.; College of Physicians and Surgeons, Baltimore, 1884; member of the Medical Association of the State of Alabama; aged 78; died, July 14, of peritonitis.

William Lee Simpson, Wellsburg, W. Va.; Western Pennsylvania Medical College, Pittsburgh, 1902; member of the West Virginia State Medical Association; aged 64; died, July 15, of coronary thrombosis.

William Duncan Lockwood, Portland, Ore.; University of Missouri School of Medicine, Columbia, 1893; member of the Oregon State Medical Society; aged 70; died, July 18, of coronary occlusion.

Frank Morris Biddle * Battle Ground, Ind.; Fort Wayne College of Medicine, 1895; county health officer; aged 65; died, July 27, 1939, in St. Elizabeth Hospital, La Fayette, of pulmonary fibrosis.

Pasquale Edoardo Maiello, Providence, R. I.; College of Physicians and Surgeons, Boston, 1922; Tufts College Medical School, Boston, 1923; served during the World War; aged 41; died, July 19.

Frederick Jacob Haendel, New York; University of Vermont College of Medicine, Burlington, 1898; aged 73; died in June in St. Luke's Hospital of arteriosclerosis, myocarditis and nephritis.

George Weldon Oliver, Medina, Tenn.; University of Nashville Medical Department, 1900; member of the Tennessee State Medical Association; aged 70; died, July 9, of coronary occlusion.

Edgar Palmer Peake, Oshkosh, Wis.; McGill University Faculty of Medicine, Montreal, Que., Canada, 1900; served during the World War; aged 64; died, July 27, of coronary occlusion.

George Wilton Moorehouse, Cleveland; Harvard Medical School, Boston, 1897; formerly chief of the city bureau of communicable diseases; aged 72; died, July 14, of carcinoma of the pancreas.

George Regard Beridon, Opelousas, La.; Tulane University of Louisiana School of Medicine, New Orleans, 1915; member of the Louisiana State Medical Society; aged 48; died, July 27.

William Breen, Oxford Junction, Iowa; State University of Iowa College of Medicine, Iowa City, 1908; aged 56; died, July 24, in a hospital at Iowa City of urethral stricture and rupture.

John Bennett Townsend * Anderson, S. C.; University of Virginia Department of Medicine, Charlottesville, 1896; on the staff of the Anderson County Hospital; aged 68; died, July 13.

Henry Lazaar, Memphis, Tenn.; University of the South Medical Department, Sewanee, 1901; aged 61; died, July 30, in St. Joseph's Hospital of arteriosclerosis and coronary thrombosis.

James Beverly De Shazo, Ridgeway, Va.; Bellevue Hospital Medical College, New York, 1892; member of the Medical Society of Virginia; aged 70; died, July 31, of coronary occlusion.

Alphonse J. Kennedy Genella, Kenner, La.; Tulane University of Louisiana School of Medicine, New Orleans, 1895; president of the parish board of health; aged 67; died, July 11.

Edmond Ray Keith, Lawrence, Kan.; American Medical College, St. Louis, 1891; member of the Kansas Medical Society; aged 75; died, June 29, in the Lawrence Memorial Hospital.

Barnard Tillman Bridges, Hartford, Ala.; University of Alabama School of Medicine, 1909; member of the county school board; aged 55; died, July 18, in a hospital at Dothan.

Warner Latta Crouch * Fairview, Ill.; Rush Medical College, Chicago, 1912; served during the World War; aged 54; died, July 21, in the Graham Hospital, Canton, of uremia.

David C. Wylie Jr. * Aspermont, Texas; Baylor University College of Medicine, Dallas, 1928; aged 39; died, July 5, of pneumonia as the result of a self-inflicted bullet wound.

Charles J. Kehm, Newport, Ky.; Eclectic Medical Institute, Cincinnati, 1896; member of the Kentucky State Medical Association; formerly health officer; aged 70; died, July 12.

Thomas Taylor Cosgrove, Sylvania, Ohio; Northwestern Ohio Medical College, Toledo, 1888; aged 78; died, July 29, in a hospital at Toledo following an automobile accident.

Fielding G. Carroll, Cave City, Ky.; University of Louisville School of Medicine, 1910; member of the Kentucky State Medical Association; aged 58; hanged himself, July 7.

Randolph McCutcheon, South Charleston, W. Va.; Medical College of Virginia, Richmond, 1924; served during the World War; aged 48; died, July 28, of coronary thrombosis.

Louise Di Moja, New York; New York Medical College and Hospital for Women, New York, 1907; aged 54; died, July 5, in Long Branch, N. J., of coronary occlusion.

William Henry Hinklin, Marion, Ohio; Eclectic Medical Institute, Cincinnati, 1891; formerly county coroner; aged 81; died, July 27, in Columbus of organic heart disease.

Lynn Arthur Martin, Binghamton, N. Y.; New York Homeopathic Medical College, New York, 1886; aged 74; died, July 20, of diabetes mellitus and angina pectoris.

John Calhoun Wilkins, Beekman, La.; Memphis (Tenn.) Hospital Medical College, 1892; aged 72; died, July 22, in a hospital at Bastrop of cerebral hemorrhage.

Charles Monroe Campbell, Ralph, Ala.; University of Tennessee Medical Department, Nashville, 1894; aged 72; died, July 22, of carcinoma of the prostate.

Oscar Bernard Payne, Chicago; Chicago Medical School, 1923; aged 50; died, July 3, in the Provident Hospital of pulmonary embolism from thrombophlebitis.

Tully M. Talbot, Valdosta, Ga.; Columbus Medical College, 1888; member of the Medical Association of Georgia; aged 79; died, July 9, in Austin, Texas.

Ellis Charles Brown, Portland, Ore.; University of Michigan Homeopathic Medical School, Ann Arbor, 1880; aged 86; died, July 1, in the Emanuel Hospital.

William J. Wick, Chicago; Rush Medical College, Chicago, 1890; member of the Illinois State Medical Society; aged 72; died, July 29, of chronic myocarditis.

Henry C. Holtzendorff, Mishawaka, Ind.; Medical College of Indiana, Indianapolis, 1895; formerly county coroner; aged 68; died, July 30, of heart disease.

Bruce Blance Mitchell, Tuscaloosa, Ala.; Meharry Medical College, Nashville, Tenn., 1903; aged 53; died, July 24, of mitral lesion with decompensation.

John Cantzon Foster, Tampa, Fla.; Medical College of Virginia, Richmond, 1901; aged 63; died, July 22, in Timmons-ville, S. C., of lobar pneumonia.

Henry Jones, Coolidge, Ga.; Atlanta Medical College, 1895; member of the Medical Association of Georgia; aged 68; died, July 7, at Milledgeville.

Aaron Friedman, Hoboken, N. J.; Jefferson Medical College of Philadelphia, 1902; aged 75; died, July 14, at the Mount Sinai Hospital, New York.

Edward Patrick Philbin, Buffalo; University of Buffalo School of Medicine, 1922; aged 41; was drowned, July 7, when his motor boat capsized.

Janet Leah Long-McCollum, Oak Park, Ill.; Illinois Medical College, Chicago, 1896; aged 79; died, July 30, of carcinoma of the uterus.

Harry Lawrence Rubin, Chicago; Loyola University School of Medicine, Chicago, 1922; aged 43; died, July 5, of rheumatic heart disease.

Benjamin Tappan Loring * Watertown, Mass.; Boston University School of Medicine, 1898; aged 70; died, July 29, of coronary heart disease.

Arthur J. Childress * Jefferson, Texas; Eclectic Medical University, Kansas City, Mo., 1915; aged 56; died, July 29, of coronary occlusion.

Don Wilson Vanderhoof, Omaha; Creighton University School of Medicine, Omaha, 1913; aged 52; died, July 28, of Hodgkin's disease.

Henry Wasson Baskette, St. Louis; University of Nashville (Tenn.) Medical Department, 1882; aged 78; died, July 15, of carcinoma.

Alfred Merritt Sorell ☉ Baltimore; College of Physicians and Surgeons, Baltimore, 1907; aged 57; died, July 21, of pylonephrosis.

William H. Wethers, Baton Rouge, La.; Meharry Medical College, Nashville, Tenn., 1910; aged 57; died, July 20, in New Orleans.

William Hunter Haw, Atlanta, Texas; Tulane University of Louisiana School of Medicine, New Orleans, 1928; aged 36; died in July.

Armand Lafleur, Lawtell, La.; Louisville (Ky.) Medical College, 1889; aged 68; died, July 11, of cardiac decompensation and pellagra.

Charles Alvin Portz ☉ Canton, Ohio; Ohio Medical University, Columbus, 1905; aged 62; died, July 10, of coronary thrombosis.

Edmund Burke Hardin, Lakeland, Fla.; Louisville (Ky.) Medical College, 1896; aged 65; died, July 8, of carcinoma of the larynx.

Charles Franklin Bryan, Corsicana, Texas (licensed in Texas under the Act of 1907); aged 64; died, July 5, of coronary occlusion.

Charles Lewis Crow, Columbus, Ky.; St. Louis College of Physicians and Surgeons, 1908; aged 71; died, July 18, of carcinoma.

Joseph Sterling Yount, Chicago; Rush Medical College, Chicago, 1893; aged 72; died, July 17, in the Illinois Central Hospital.

Max L. Rich, Grand Island, Neb.; Omaha Medical College, 1893; aged 68; died, July 18, of chronic myocarditis and hypertension.

Irving Layton Drake, Durant, Okla.; Gate City Medical College, Dallas, Texas, 1907; aged 59; died, July 21, of a heart stroke.

William H. Emery, Lorain, Ohio; Toledo Medical College, 1898; veteran of the Spanish-American War; aged 65; died, July 19.

Joseph Etienne Germain, Rimouski, Que., Canada; Laval University Faculty of Medicine, Quebec, 1913; aged 52; died, July 3.

Elmer C. Hanson ☉ Austin, Minn.; University of Minnesota Medical School, Minneapolis, 1922; aged 42; died, June 23.

Chando H. Malcolm, Huntington, W. Va.; University of Louisville (Ky.) Medical Department, 1892; aged 68; died, July 17.

James D. Meadow, Sherman, Texas; Pulte Medical College, Cincinnati, 1891; aged 77; died, July 14, of heart disease.

F. H. Blount, Snow Hill, N. C. (licensed in North Carolina in 1885); aged 83; died, July 29, of coronary occlusion.

Olafur Stephenson, Winnipeg, Man., Canada (licensed in Manitoba in 1895); aged 74; died, July 17, of pelvic abscess.

Charles John Wood ☉ Genoa, Ohio; St. Louis University School of Medicine, 1933; aged 35; died suddenly, July 10.

Nicholas Boniface Pautler, Waterloo, Ill.; Missouri Medical College, St. Louis, 1893; aged 67; died, July 18.

Joseph R. Conyers, Gates, Tenn.; Memphis Hospital Medical College, 1888; aged 77; died, July 9, of pneumonia.

John Thomas Norman, Sharon, Miss.; Memphis (Tenn.) Hospital Medical College, 1894; aged 73; died, July 15.

David Thomas White, Blackford, Ky.; Kentucky School of Medicine, Louisville, 1885; aged 80; died, July 28.

Charles Forrest Alexander, Gratz, Ky.; Kentucky School of Medicine, Louisville, 1893; aged 70; died, July 26.

Abner Dale Neely, Lynch, Neb.; Marion-Sims College of Medicine, St. Louis, 1900; aged 80; died, July 23.

Elmer Newkirk Funk ☉ Shreve, Ohio; Starling Medical College, Columbus, 1903; aged 60; died, July 19.

Charles Pelham Ward, Atlanta, Ga.; Southern Medical College, Atlanta, 1894; aged 69; died, July 30.

James Coleman Fisher, Jefferson, Ohio; Rush Medical College, Chicago, 1889; aged 80; died, July 21.

Abram Jay Hansberry, Ozark, Ark. (licensed in Arkansas in 1903); aged 75; died, July 31, of sarcoma.

Harvey Dorman Kemper, Jonesboro, Ga.; Atlanta School of Medicine, 1909; aged 60; died, July 14.

Edward C. Duddy, Indianapolis; Hering Medical College, Chicago, 1899; aged 72; died, July 2.

William A. Musmann, Denver; Denver Homeopathic College, 1901; aged 74; died, June 22.

Bureau of Investigation

ANOTHER BRINKLER FRAUD ORDER

Long Time Diet Faker Is Once More Debarred from the Mails

The issuance of a Post Office fraud order against George H. Brinkler, of Miami Beach, Fla., on Oct. 21, 1938, and the release of a "cease and desist" order by the Federal Trade Commission on May 27, 1939, against the same individual, recall the many instances in which this self-styled "food expert" has had the rather dubious distinction of receiving the attention of the federal authorities.

For nearly thirty years Brinkler's meanderings in the diet field have been followed by the Bureau of Investigation of the American Medical Association. A case in which the Post Office Department declared the business of Brinkler (then operating from Washington, D. C.) to be fraudulent, obtained an indictment against him and debarred him from the use of the mails was reviewed in THE JOURNAL, Oct. 3, 1914. The

government investigation had revealed Brinkler's literature as representing that his diet advice would, if followed, cure all diseases including even cancer, diabetes and Bright's disease. Brinkler has also claimed that certain foods cause tumors, coughs or catarrh to disappear, that too much cream, butter and cheese produce deafness and discharging ears, and that some foods make one nervous, whereas others bring about "the finest quality of Vitality, Electricity, Magnetism or Intelligence."

The suckers who sent 10 cents for Brinkler's "valuable instructive booklet" entitled "The New Brainy Diet System"

**REMEMBER MY
ADDRESS
IN THE HOUR
OF APPROACH-
ING DEATH**

If you do not write now, be sure to put this booklet away carefully for future reference when sickness suddenly attacks you or your friends. I will send you another copy, to hand to a friend, if you let me know.

To remember my name and address may save valuable lives! When suddenly taken ill, you will not be scared to death through ignorance of the cause of your disease, but an intelligent self-confidence will make you hopeful as soon as you have learned the cause and cure of your attack.

Remember, when doctors despair of your life, in the hour of approaching death, that vital or brainy foods have restored the dying to robust health with the help of a competent teacher.

Read my testimonials attentively! They prove my efficiency in the cure of disease by vital or brainy foods.

Invitation to a Food Talk

Mrs. Mortimer, 25 Howard Road, Shaker, Vermont, writes:

"I have been a sufferer from indigestion for many years. I have tried many remedies, but have not been able to get well. I have read your book, 'The New Brainy Diet System,' and have followed your advice. I am now well and happy. I am sure that your book is a great help to many people who are suffering from indigestion. I am sure that your book is a great help to many people who are suffering from indigestion. I am sure that your book is a great help to many people who are suffering from indigestion."

G. H. BRINKLER
FOOD EXPERT
WASHINGTON, D. C.

Some of Brinkler's advertising of over twenty-five years ago.

found that, instead of giving advice on diet, it was merely a come-on to get them to invest in Brinkler's "course." The booklet consisted largely of endorsements including one from a prolific producer of fake analyses and worthless testimonials. Further, Brinkler played up "scare stuff," such as "Remember my Address in the Hour of Approaching Death." With his booklet Brinkler sent out a "Question List" blank, to be filled out by the recipient and returned to Brinkler with \$1. At least in some replies, Brinkler declared that the various disorders listed in the "answers" were due to improper diet. If one wanted to know just what constituted proper diet, he usually was asked to send Brinkler \$40, \$60 or \$75, as the case might be.

On May 22, 1914, Brinkler was called on to show cause why a fraud order should not be issued against him. After a continuance had been granted him the hearing of the charges began and continued for ten days. Brinkler was then allowed three weeks in which to file a brief which, when submitted, was followed by an additional one and further evidence. These were carefully reviewed by the Solicitor for the Post Office Department, who brought out these facts: That in one case symptoms that might have been due to carcinoma of the stomach were "diagnosed" by Brinkler as due to improper diet; that another case, suggesting serious disease of the uterus, a further one indicating syphilis and one described as a well developed case of diabetes in a 12 year old boy were all diagnosed by Brinkler as due to faulty diet. Apparently Brinkler was giving the same

report in all cases, no matter how serious. Further, it was brought out that Brinkler was not a Doctor of Medicine, had no education in medical subjects and that girl clerks also lacking in medical knowledge used "form" paragraphs tabulated under symptoms in formulating replies to inquiries.

It was further shown that, when a woman wired Brinkler for advice in the case of an overgrown boy suffering from acute pulmonary tuberculosis involving both lungs, Brinkler asked her to wire \$40 "for quick relief followed by complete course." The woman sent the money and received instructions as to what food the boy should and should not have. Soon afterward the boy was taken to a sanatorium and died. In spite of the mother's destitute circumstances, Brinkler refused to make any refund. This case was only one piece of evidence brought against Brinkler, leading up to the issuance of a fraud order against him on Aug. 19, 1914.

This did not, however, end the matter, for Brinkler contested the order and on Jan. 16, 1917, following a trial lasting three weeks, and after a twenty hours deliberation by a jury, Brinkler was acquitted of the criminal charge of using the mails to defraud. Involved in this decision, of course, was the difficulty confronting the prosecuting attorney of proving to the unanimous satisfaction of all the jurors not only that Brinkler's claims were false but that Brinkler *knew they were false*. Nevertheless, as the fraud order denying him the use of the mails still held, Brinkler applied for a ruling to set aside this disbarment but his appeal was denied. It is worth noting that in April 1915 and May 1916 the fraud order had been extended to cover the names of certain obscure individuals who appeared to be continuing this business under different titles.

For a time thereafter Brinkler was said to advertise in the newspapers of Washington, D. C., where he was located, and it appears that his business was limited to the readers of those papers and that they had to come to him as he advertised his office hours. Apparently, however, he finally decided to flout the Post Office fraud order, for in 1919 he was advertising from Atlantic City as the "Brinkler Institute." Around 1921 and apparently up into 1932 he was heard from in New York City, operating variously under the names "Brinkler School of Eating," "Brinkler Institute" and "Brinkler School and Dining Rooms" and his advertising indicated that he was using the mails. Some of his New York circulars announced him as "Manager" and named as the "Medical Director" one W. Wallace Fritz, who, although holding the degree of M.D., has helped promote various kinds of quackery and pseudomedicine and appears to have claimed "degrees" in chiropractic, osteopathy and some other things.

As many quacks and faddists move on to warmer climes in the winter, when business is good there, it is not surprising that in 1933 Brinkler was heard from at Miami Beach, where he was reported to be running a "Brinkler Institute."

The Post Office Department entered the picture again on March 25, 1938, when it called on the Brinkler Institute, the Brinkler School of Eating, "Dr." George H. Brinkler, J. Collins, F. Schumann and their officers and agents as such to show cause on May 4, 1938, why a fraud order should not be issued against them. Brinkler's attorney applied for an adjournment of the hearing for ninety days but the application was denied. Brinkler himself then asked for and obtained a postponement of at least a month. On May 26 Brinkler appeared at the hearing with a new attorney, who at the close of the testimony asked for a continuance until June 6, which was granted. On that date Brinkler came to the hearing without his attorney, Mr. Rowan, and the court put on record a telegram it had received from Rowan stating that he would not come to Washington to represent Brinkler further until the latter made satisfactory financial arrangements with him. Brinkler was thereupon granted a further continuance of one day to secure other counsel.

The hearing duly opened on June 7 and continued for five days. The Post Office reviewed the previous fraud order against Brinkler and its two extensions to cover other names. Further, it showed that in February 1927 Brinkler had been convicted in New York City on the charge of practicing medicine without a license and sentenced to spend six months in the workhouse or to pay a fine of \$500. He chose to do the latter. In June of that year the appellate division of the New York Supreme Court upheld the sentence.

The Post Office also brought out that Brinkler had been representing that he could cure arthritis, gallstones, tuberculosis, tumors, cancer, diabetes, hardening of the arteries, high blood pressure, uterine disorders, apoplectic strokes and some other things; that there was "No Knowledge of Nutrition Without Brinklerism"; that "100% Improvements in 30 Days in Our Dining Room" were "guaranteed"; that "Dr. Brinkler is the oldest, most experienced, daringly original experimentalist in nutrition anywhere . . . has taught over 50,000 students, 99% successes"; and that he "lived over 35 years without drinking water."

The Post Office also showed that, whereas the "student" or "patient" paid a \$30 fee for a course of "lessons" which purported to eliminate and cure disease by dietary rules that were represented as "individualized" to suit the particular case, these actually were mimeographed in form and generalized in content. The government introduced witnesses of high standing in the scientific world who discredited Brinkler's theories and claims.

Brinkler's first witness was a Fred W. Collins of Newark, N. J., naturopath and osteopath, whose testimony disclosed that he was not thoroughly familiar with Brinkler's methods and that these were substantially different from the ones he (Collins) used. Collins's testimony, it was said, further revealed that he possessed only a limited knowledge of dietetics.

Brinkler's second witness was introduced as Dr. George Joseph of Morgantown, W. Va., who testified that he was cured of diabetes by following Brinkler's treatment, though he could not explain the how or the why thereof. He admitted that his only knowledge of Brinkler's tenets was obtained through a reading of the latter's book, "Foresight—Foundation of Fortune," which the government showed to be essentially a book about social and economic conditions! Furthermore, from the evidence, the Post Office expressed serious doubt that the witness had ever had diabetes at all. Dr. Joseph received a diploma from the Eclectic Medical Institute, Cincinnati, in 1890 and a West Virginia license under the "years of practice" act. He is not a member of his local society or of the American Medical Association.

Then there was testimony offered for Brinkler by George E. Crandall of York, Pa., which was described in the Post Office report as "evasive and contradictory," in that this witness admitted he was not familiar with the dietary offered by Brinkler. The government report of the hearing commented that "Dr. Crandall's methods seem to be epitomized in his remark that although not subscribing to orthodox views he makes orthodox examinations to 'more or less fool the people.'" Crandall appears to be an osteopath and was himself requested by the Federal Trade Commission in 1938, when trading as "Dr. Crandall's Standard Institute," to discontinue making certain false claims for the alleged results of his mail-order "course in natural therapeutics."

Two lay witnesses also were presented by Brinkler but apparently did not help his case. Brinkler himself, though present at all the hearings, did not testify in his own behalf. He did obtain permission to file a brief. In this he lengthily expounded his views, which the Post Office Department could not consider seriously as he had been given ample opportunity to state his case during the hearings. His brief was reported to be largely a tirade against scientific medicine and a defense of the "naturopathic school of healing," all of which was beside the point as the government had neither defended the former nor attacked the latter. The proceedings brought out the fact that though Brinkler claimed to be a licensed naturopath his system did not conform to the naturopathic teachings, most of which, in fact, he appeared to repudiate. Also emphasized was the man's fundamental ignorance of the science of dietetics and nutrition as indicated by his attitude toward the scientific chemical analysis of foods into protein, carbohydrate and fat, which he termed ridiculous. In view of these and other facts the fraud order was issued against him on Oct. 21, 1938.

Meanwhile another government agency had taken cognizance of Brinkler's fakish claims. On Nov. 29, 1935, the Federal Trade Commission issued a complaint against George Henry Brinkler, operating from Miami Beach, Fla., under such names as "Brinkler School of Eating," "Brinkler School of Food Science," "Brinkler School of Nutrition" and "Brinkler Institute." Among the misrepresentations charged against the man

were that his correspondence course provided a competent treatment for all diseases and that his outlined method of diet was adequate for any of the thirty-six disorders listed, including indigestion, bronchitis, tuberculosis, hardening of the arteries and many others. Finally, on May 27, this year, the commission definitely ordered Brinkler to cease making the false representations named and some others, such as that persons who took his "courses" would achieve improved memory and eyesight, normal circulation, doubling of brain or muscle power, and a few other marvelous results.

Whether, in view of the fraud order of last October, Brinkler already had ceased to advertise and had discontinued his business by the time the Federal Trade Commission's order was issued is not evident, but if one may judge by his persistence in defying the original fraud order of 1914 he will be heard from again some of these days. In the meantime it is earnestly hoped that the public becomes slightly acquainted with the barest elementary facts concerning diet and nutrition, for that would be sufficient information to enable one to recognize Brinkler's folderol as fakery.

MISBRANDED "PATENT MEDICINES"

Abstracts of Notices of Judgment Issued by the Food and Drug Administration of the United States Department of Agriculture

[EDITORIAL NOTE.—The abstracts that follow are given in the briefest possible form: (1) the name of the product; (2) the name of the manufacturer, shipper or consigner; (3) the composition; (4) the type of nostrum; (5) the reason for the charge of misbranding, and (6) the date of issuance of the Notice of Judgment—which is considerably later than the date of the seizure of the product and somewhat later than the conclusion of the case by the Food and Drug Administration.]

Brown's Nosopen.—Am-Bro Co., Lawton, Okla. Composition: "Treatment No. 1," essentially water with small amounts of ephedrine sulfate and chlorbutanol; "Treatment No. 2," essentially mineral oil with small amounts of ephedrine and volatile oils, including those of eucalyptus and camphor. Fraudulently represented as a cure for hay fever, asthma, nasal catarrh and sinus headaches.—[N. J. 28737; November 1938.]

Diatine.—Scheidemann Remedy Co., Milwaukee. Composition: Essentially a coarsely ground plant material, chiefly juniper wood, bark, needles and berries, and small amounts of bearberry and senna leaves. Fraudulently represented as a treatment for diabetes.—[N. J. 28739; November 1938.]

Exanthum Oil.—William H. Trentlage, Elgin, Ill. Composition: An oily liquid containing fixed oils resembling those of olive and croton. Fraudulently represented as a remedy for sinus trouble, infected tonsils, appendicitis, toothache, rheumatism, etc.—[N. J. 28982; November 1938.]

Ferro China-Tonico Tessitore.—Tessitore's Chemical Mfg. Co., Inc., Providence. Composition: Essentially alkaloids of cinchona and a small amount of iron and ammonium citrate, with arsenic, saccharin, alcohol and water. Fraudulently represented as a remedy for fevers and a cure for headache, nausea, anemia, etc.—[N. J. 28708; November 1938.]

Flu-Go Mutton Suet.—Keystone Laboratories, Memphis. Composition: Essentially volatile oils including menthol, camphor and wintergreen, and a small amount of turpentine, in a mutton-fat base. Fraudulently represented as a treatment for influenza, sore throat, burns, etc.—[N. J. 28743; November 1938.]

Hayssen's (Dr.) Supreme Goitre Ointment.—H. H. Hayssen Co., and Hayssen Laboratories, Mobile, Ala. Composition: Potassium iodide (8.5 per cent) and small amounts of turpentine and rose perfume, in a petrolatum base. Fraudulent therapeutic claims.—[N. J. 28744; November 1938.]

Hayssen's (Dr.) Supreme Goitre Tablets.—H. H. Hayssen Co., and Hayssen Laboratories, Mobile, Ala. Composition: In each tablet, 0.163 grain of potassium iodide with inert ingredients such as sugar, starch and talc. Fraudulently represented as a remedy for goiter, tonsillitis, tumors, blood and nerve disorders, etc.—[N. J. 28744; November 1938.]

Liberty Blood Tonic.—National Medicine Co., Nashville, Tenn. Composition: Essentially extracts of plant drugs including a laxative and an alkaloid-bearing drug, compounds of iron, sodium benzoate, alcohol (7.2 per cent by volume), sugar and water. Fraudulent therapeutic claims.—[N. J. 28988; November 1938.]

National Kidney Preparation.—National Medicine Co., Nashville, Tenn. Composition: Essentially extracts of plant drugs, potassium acetate, sodium benzoate, alcohol (8.13 per cent by volume), sugar and water. For backache, bearing-down pains, lumbago, kidney and bladder troubles. Fraudulent therapeutic claims.—[N. J. 28988; November 1938.]

Pancreatone Capsules.—Crescent-Kelvan Co., Philadelphia. Composition: Glandular material and compounds of manganese, strychnine, arsenic and gentian. Fraudulently represented as a cure for diabetes and diseases generally of pancreatic origin.—[N. J. 28742; November 1938.]

Correspondence

THE BIOLOGIC ASSAY OF MIXTURE OF ACTIVE PRINCIPLES

To the Editor:—Expositions of the principles of biologic assay such as those by Dale and by Burn have done much in recent years to diffuse an understanding of the logical basis of the method. The principles seem so simple and so obvious that one may easily come to observe them in a literal, perfunctory manner without realizing how easily this may lead to fallacy.

Especially in the cases in which the drug to be assayed consists of a mixture of active components does it seem that a clarification of the principles is desirable. In this category, unfortunately, are some of the drugs for which biologic standardization is most essential. Digitalis, being one of the most important and most troublesome, will be considered in some detail.

That the drug must be compared with a standard which contains the same active principle is now generally realized; yet the difficulty of finding such a standard is not readily apparent. Objection was quite justifiably made to the use of ouabain as a standard for the assay of digitalis; but merely because a standard has now been adopted which has the name digitalis, one must not fall into the complacent assumption that all the logical requirements have been met.

A biologic assay is usually performed to determine therapeutic effectiveness in man, and the result is expressed in the form of a ratio which purports to represent the therapeutic activity of the tested preparation relative to a standard. If the drug assayed consists of a mixture of principles having qualitatively similar actions, to ascribe any such significance to this ratio involves one of the following assumptions: Either (1) all samples of the crude drug (including the standard) contain the several active principles in the same proportions or (2) the ratio of the dose producing the therapeutic action in man to the dose producing the observed action in the test animal is the same for each of the several principles.

The first assumption will be conceded to be not generally true. The fallacy involved in the alternative assumption is not so obvious. It is this proposition, probably, which is tacitly accepted in some standard procedures. The fact that the various antirachitic substances differ among themselves in their effectiveness in chickens relative to that in rats and the fact that one of the digitalis glucosides, gitalin, is reported to be three times as active therapeutically as was to have been expected from the biologic assay should constitute sufficient warning that any such assumption is unworthy of a priori acceptance.

Certain aspects of the therapeutic use of the cardiac glucosides add further confusion to the consideration. The glucosides differ greatly among themselves in the persistence of their action. A dose of a short acting glucoside and a dose of a long acting glucoside which are equivalent in the cat assay will obviously not be equivalent in maintaining digitalization in a patient. Moreover, the therapeutic effect itself, while imperfectly understood, undoubtedly is not one simple action. At least two effects, that on atrioventricular conduction and that on the efficiency of myocardial contraction, are involved in the usual therapeutic applications. It is not evident that the relative effectiveness in these two actions is the same for all the cardiac glucosides. If not, two glucoside preparations which are therapeutically equivalent for a patient with auricular fibrillation might not be equivalent for a patient with congestive failure without fibrillation.

These considerations force one to conclude that it is impossible to devise a scientifically sound biologic assay for a drug such as digitalis. The objection may be made that such caviling is sterile pedantry—that the physiologic standardization of digitalis is a practical necessity, a practical success. It must be conceded that the usual assays of digitalis are sufficiently accurate for most clinical purposes. This is so because the two assumptions mentioned, while not true, are almost true. So far as either of these assumptions approaches the truth, the result of the assay approaches the therapeutic significance imputed to it. The assay will always be a compromise between logical integrity and the necessities of practical affairs and must be accepted with reservations.

Much work has been applied to the biologic assay of digitalis in the standardization of technic and in the mathematical analysis of animal responses. While it is laudable to try to eliminate all avoidable sources of error, much of this work must be considered a labor of futility. Furthermore, preoccupation with refinements has almost blinded some investigators to the fact that they are measuring something having no exact meaning in reality. However refined the technic, however refined the statistical treatment, the result cannot be more valid than the premises on which the method is based. There is need that more energy be devoted to the rigorous examination of the logical basis of biologic assays before it is profitable further to polish the technic of their performance.

THOMAS C. BUTLER, M.D., Nashville, Tenn.

Assistant Professor of Pharmacology,

Vanderbilt University School of Medicine.

INTRA-GROUP AGGLUTINATION

To the Editor:—In THE JOURNAL July 8, page 126, appeared an article by Levine and Stetson concerning a case of intra-group agglutination (immune iso-agglutination) after repeated transfusions. It makes no reference to my publication on the same subject in *Klinische Wochenschrift*, Nov. 14, 1936, page 1675. It must be emphasized that in the European literature there were five cases previous to mine in which sensitization was demonstrable of the red blood cells to blood of its own group. Only Deutsch's case resembled Levine and Stetson's; therein the symptoms of iso-immunization disappeared in a few weeks. In my case all samples of the B group blood cells showed agglutination without exception with the serum of the sensitive patient belonging to the B group, and none of the O group blood cells evidenced these symptoms. So it could be demonstrated by the indirect method that the immunization depends on the B factor and has nothing to do with the M, N and P factors. The direct method was not possible because the patient died a few days after the phenomenon of aplastic anemia appeared. The possibility, however, that the reaction becomes weaker and disappears in several weeks could therefore also not be excluded. But in spite of the short time that elapsed between the appearance of the symptoms and death, the determination of the titer of agglutination and the absorption of the anti-A agglutinins (normal agglutinins) was also possible. In view of the fact that the B group factor (agglutigen) showed properties of antigen, its nature could be explained as albumin-like substance.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

ACUTE LYMPHATIC LEUKEMIA

To the Editor:—A 10 year old girl became ill June 1 with pain in the right shoulder. On June 15, pain and swelling of the left ankle with low grade fever set in. She was sent to the hospital June 26 with enlarged spleen and liver and palpable glands in the neck, axillas and groins. Several petechial spots were present; the temperature was 102 F. Blood study showed hemoglobin 48 per cent, red blood cells 3,040,000, white blood cells 2,150, polymorphonuclears 16 per cent, small leukocytes 50 per cent, large leukocytes 32 per cent, eosinophils 2 per cent and platelets greatly reduced; there was slight variation in size and shape of the red blood cells with moderate basophilic stippling; the reticulocyte count was 0.5 per cent; fragility test showed hemolysis complete in a 0.32 per cent solution and beginning in a 0.38 per cent solution; the sedimentation rate was 18 minutes; no growth occurred in blood culture. The Wassermann reaction was negative; x-ray study of the chest was negative. The diagnosis was acute aleukemic leukemia of the lymphocytic type. Treatment consisted of eight transfusions during the past seven weeks; ascorbic acid, liver extract and a high vitamin diet together with ultraviolet radiation from an air-cooled quartz mercury vapor arc lamp; roentgen irradiation of the spleen has been considered but not used. Four or five attacks of epistaxis occurred during the first month in the hospital and seemed to follow shortly after the transfusions were given. On July 3 the white cells had decreased to 750 with 7 per cent polymorphonuclears and 93 per cent small lymphocytes. On July 28 there were 11,000 white blood cells and apparently a remission of the symptoms. On August 4 there began a daily rise of temperature to 103 F. Two days later a sudden attack of severe upper abdominal pain with marked tenderness over the splenic area occurred. The tenderness disappeared in twenty-four hours. There has been gradual remission of symptoms until the present time, when the temperature in the afternoon is 101 F. The blood count August 16 showed hemoglobin 68 per cent, red blood cells 3,820,000, white blood cells 2,300, polymorphonuclears 36 per cent, small lymphocytes 62 per cent and large lymphocytes 2 per cent. The spleen has increased and decreased in size with the exacerbations and remissions of the disease, but the glands in the neck, axillas and inguinal region have remained as at first described—just palpable. Thank you for any assistance.

M.D., Glen Cove, N. Y.

ANSWER.—This is apparently typical lymphatic leukemia of the acute or subacute type. No mention is made regarding the immaturity of the lymphocytes in the blood, but it is assumed that most of the large lymphocytes are lymphoblasts. Although no really curative treatment is known for any type of leukemia, it is of value to distinguish between the acute and the chronic forms because of roentgen therapy. This is contraindicated in the acute and subacute forms but may be fairly effective for a time in chronic leukemia. The treatment being given in this case is all that can be done unless the chronic form develops, in which case roentgen treatment should be used.

PAINFUL STIMULI OF THE TEETH

To the Editor:—Will you please explain the physiology or pathology involved in the production of pain in the contact of sweets with an open cavity in a tooth. Since direct contact does not seem to be an essential factor and because the reaction is so rapid, I should like to know whether the production of pain is chemical or physical in nature. Even though the problem seems at first glance simple, I have been unable to explain it satisfactorily to myself.

M.D., New York.

ANSWER.—The exact mechanism for the production of pain from stimuli acting on the substance of the tooth is not clearly understood in all its details. Chemical and physical changes affecting first the tissue fluid within the dentin appears to stimulate the nerve endings of the nonmyelinated nerve fibers within the tooth. There is considerable controversy at the present time as to whether these nerve endings are limited to the arborization about the body of the odontoblasts, whether they extend with the odontoblastic fiber (Tomes fiber) in the dentinal tubules or whether, as some believe, they reach farther and are incorporated within the calcified substance of the dentin. Recently investigators, holding to the latter contention, believe that the failure of others to recognize these endings within the dentin has been due to the particular histologic technics used in the preparation of the tissue for study.

Stimuli arising through changes in temperature, pressure, surface tension and hydrogen ion concentration may be transmitted through the tissue fluid and in turn the fibers of the odontoblasts and from the odontoblastic substance to the nerve endings which are in contact either with the nerve endings within the dentinal tubule or the body of the cell which lies at the pulpal extremity

of the dentinal tubule. The stimulus reaching the afferent nerve fiber in this way is transmitted by them as they penetrate into the substance of the pulp and receive the myelinated nerve sheath before they leave the apical foramen and join their respective nerve trunk.

The enamel overlying the dentin acts as an insulation, and for this reason it may be easier to elicit reaction from stimuli at the neck of the tooth where the enamel is thin. Similarly, when the enamel has been destroyed by dental caries or any other cause the tooth may become sensitive. Conversely, in slowly progressive caries the sclerosis of which occurs as a degenerative change in the dentin the sensitivity of the tooth often decreases because of the formation of a nonvital, densely calcified substance protecting the underlying vital dentin.

EAR DROPS FOR EARACHE

To the Editor:—I should like to develop ear drops for dispensing. I have been using glycerite of phenol in 5 and 10 per cent solutions. Can you suggest a solution without the phenol that will not cost much more than the glycerite of phenol? I have these solutions made up in pints and dispense them in 2 drachm bottles.

M.D., Hamilton, Ohio.

ANSWER.—For the purpose for which it is intended—the relief of earache—there is no better medicament than glycerite of phenol in solutions of varying strengths. To remove the phenol would rob it of its efficacy. This does not mean that solutions of glycerite of phenol do not have their limitations, but these do not become evident until after forty-eight hours or so, when the disagreeable desquamation which hides the landmarks on the drum begin to appear. By this time, if the symptoms are no better, the medication should be discontinued and paracentesis done. Plain glycerin has been recommended, but it does not have the analgesic effects of solutions of glycerite of phenol, although it does not produce the desquamation of which the latter is guilty.

INSULIN REFRACTORY DIABETES

To the Editor:—I have at present under my care a patient who is apparently insulin resistant. This woman, about 50 years of age, has had hyperglycemia for the past two years. She has been given as much as 130 units of insulin a day by her local physician without effect. She is now hospitalized and is receiving 240 units of insulin a day. This does not have the slightest effect on her blood or urinary sugar. I have tried her on regular insulin, solution of zinc insulin crystals and protamine zinc insulin. They are all equally ineffective. She does not exhibit any allergic reactions to insulin. Physically she is rather short and stout, with a fairly dry skin. She has cataracts in both eyes. The remainder of her physical examination is entirely negative. I would sincerely appreciate any advice that you could give me as to the management of this case.

Leonard J. Schiff, M.D., Plattsburg, N. Y.

ANSWER.—Ever since its introduction there have been from time to time reports of unusual cases in which there is a remarkable insensitiveness to insulin. With these patients amounts of insulin as great as 200 or more units a day have been necessary. However, rarely if ever has complete resistance to insulin been demonstrated. Usually if the amount of insulin is steadily increased a point is reached at which hyperglycemia and glycosuria are controlled and further increase in insulin dosage causes hypoglycemia with the usual symptoms. One patient under observation has required from 300 to 400 units of insulin a day for almost four years, and another patient is now taking from 300 to 400 units a day, having at one time required as much as 2,270 units in a single day.

With the patient referred to by the questioner, one would advise gradual, yet steady, increase in the amount of insulin with the thought that finally a dosage will be reached to which the hyperglycemia and glycosuria will respond. During the period in which the insulin dosage is being steadily increased, frequent determinations of the amount of sugar in blood and urine should be made to avoid possible hypoglycemia. With such a patient it is imperative to carry out all possible studies to discover a cause for the insensitiveness to insulin. In certain of the cases reported in the literature, hemochromatosis, disorders of the endocrine organs other than the pancreas and extensive infection as from tuberculosis have been demonstrated. Attempts should be made to rule out particularly any disease of the pituitary gland. The function of the liver should be established by appropriate tests.

PREVENTION OF IMPETIGO IN NURSERY

To the Editor:—Is the following recognized as a standard routine hospital procedure to prevent impetigo? "After delivery cleanse baby with Mennen's oil if necessary. Then apply ammoniated mercury 2.5 per cent over entire baby. Remove ammoniated mercury in twelve hours with Mennen's oil. No water or oil bath to be given after ammoniated mercury has been removed, but cleanse face, folds, buttocks, hands with Mennen's oil as necessary. On sixth day apply ammoniated mercury 1.5 per cent and remove same in twelve hours with Mennen's oil. Apply iodine 3.5 per cent daily followed by alcohol 70 per cent until cord drops off. Wash breasts after delivery with tincture of green soap followed with alcohol. Apply lanolin to nipples and binder. All suspicious areas to be reported and baby isolated. Doctors to wear cap, gown, mask and hands scrubbed before entering nursery." Are there many hospitals which subject all newborn babies to this procedure? Does it lessen the incidence of impetigo? Is it harmful to the baby's skin and mother's breasts?

M.D., Minnesota.

ANSWER.—The routine hospital procedure to prevent impetigo in the newborn nursery infant, described by the inquirer, is a more vigorous procedure than is used by most hospitals at present. In various modifications it is recognized in some hospitals as a standard routine procedure to prevent impetigo. It undoubtedly lessens the incidence of impetigo, although other less involved methods have also prevented impetigo. Iodine used after ammoniated mercury may give rise to severe dermatitis.

Some hospitals have been successful in preventing or lessening the incidence of impetigo by modifying these methods as follows: Sterile olive or cottonseed oil is used to cleanse the baby after delivery. The infant is then given a sterile oil bath every day until the day of discharge from the nursery, when a soap and water bath is given. The 2.5 to 3 per cent ammoniated mercury is applied after the initial cleansing and again on the fifth or sixth day. Only alcohol is used on the cord. Great care is observed not to irritate or traumatize the infant's skin by too energetic rubbing and wiping.

The mother's breasts are washed with ordinary soap and water (but not followed by alcohol) the first thing in the morning. A clean towel is then laid over them. Nothing more is used on the breasts before or after nursing or the rest of the day unless they are sore or cracked, in which case special orders are issued to meet the indication. The mother should wash her hands thoroughly with soap and water before handling her breasts at nursing time. It is well for the doctor to wear sterile rubber gloves when handling the infant. Much more important than the use of antiseptic ointments, oils or solutions on the infant's skin and mother's breasts is the observation by the nurses and doctors of practically aseptic technic in routine handling of the infants. No one should be allowed in the nursery who has an infected cutaneous lesion nor should a baby be taken to the breast if the mother has any. Separate nursery utensils should be used for each baby.

Another technic that is being adopted by more and more newborn nurseries and has been successful in preventing impetigo is the initial cleansing with sterile oil of the excess vernix caseosa and blood from the face, scalp and skin folds, great care being taken not to irritate or traumatize the skin. The infant is then placed in the crib and no baths orunctions of any kind are given until the day the infant leaves the nursery. The infant is removed from his crib only to be taken to his mother. Of course vomitus and stool are cleansed off with gentle wipings of oil.

MYELORADICULITIS

To the Editor:—I have a rather interesting case of myeloradiculitis superimposed on arthritis. A woman aged 46 has had all the possible paralyses, including collapse of the right lung. She has gradually convalesced after being ill some nine months; at present there is weakness of the sphincters of the bladder as well as of the rectum. Her fingers have contracted or flexed. She suffers from low back pains. Will any kind of electrotherapy prove beneficial to her? Would any orthopedic operation be of importance relative to a return of function of the fingers? Does myeloradiculitis permanently disable the patient or will there be a slow but gradual recovery?

M.D., Pennsylvania.

ANSWER.—Myeloradiculitis is a nonspecific disease which may have many manifestations. Usually it is of sudden onset and clears up equally rapidly with little residue. Other cases show gradual improvement over a period of years but rarely is there complete cure. Physical therapy in the form of heat, massage and mild manipulation of the extremities is beneficial in hastening the recovery. Electrotherapy is usually unnecessary and of no benefit. Orthopedic procedures should not be carried out until maximal recovery has taken place, which often takes from two to three years.

CONGENITAL SYPHILIS

To the Editor:—A white woman aged 24, married but subsequently divorced, was first seen Aug. 1, 1938. Her father died of a ruptured aortic aneurysm. At five weeks of age the patient had a right hemiplegia which resulted in a spastic right hemiparesis. At 10 years of age and again at 16 there were attacks of interstitial keratitis, but the patient had never received specific treatment. An amenorrhea had been present for two months. Nausea and vomiting were the presenting complaints. Physical examination revealed sclerosis of the right ear drum with marked loss of hearing; right spastic hemiparesis; anisocoria with the right pupil smaller than the left; anterior synechia deforms contour of the left pupil; slight "ground-glass" appearance of both corneas, especially the right, and slight suprapubic, symmetrical swelling—pregnancy (intra-uterine) of 3 months. The Wassermann reaction of the blood was strongly positive. Antisyphilitic therapy was begun at once and the patient received a total of thirteen intravenous injections of mapharsen and ten doses of 1 cc. each of bismuth salicylate in oil given intramuscularly. In January 1939 the patient was delivered spontaneously of a healthy male infant with no stigmas of heredo-syphilis. The patient has had a return of headaches, which had been relieved during the pregnancy and treatment. The question now arises as to what therapy for the heredo-syphilis is needed or justifiable. The Wassermann reaction of the blood at present is positive.

M.D., Oklahoma.

ANSWER:—It is important to determine whether the patient's headaches are due to congenital syphilis or to some other cause and particularly important to decide whether this symptom or any part of the patient's clinical picture is due to active neuro-syphilis. It is suggested that lateral and anteroposterior roentgenograms of the head be taken and that the spinal fluid be examined at once.

If the spinal fluid is negative, it may be assumed that the majority of the patient's present objective signs are the residuums of old lesions during infancy and adolescence. Under these circumstances and whether or not the patient has an old osteitis of the skull, further treatment is to be regarded as prophylactic rather than as curative. In this case it is desirable to carry on with routine standard antisyphilitic treatment with alternating courses of an arsenical and of bismuth for a total period of about eighteen months dating from the original treatment.

Since the patient had a hemiplegia at the age of 5 weeks, it may be confidently assumed that there was once, if there is not now, severe involvement of the cerebral blood vessel. The point that now needs determination is whether there is also parenchymal involvement with the possibility of beginning juvenile dementia paralytica. If the spinal fluid is strongly positive, it is desirable to manage the patient as if she actually or potentially had dementia paralytica, first with fever therapy, preferably by induced malaria, and subsequently with trypan-blue and bismuth, treatment being continued for a minimum period of from two to three years.

RESIDUAL THROMBOPHLEBITIC EDEMA

To the Editor:—About one week after he suffered an infected lacerated wound of the left index finger a patient had an infarction of the base of the right lung. Two weeks later his right lower extremity became swollen and painful and a tender mass was palpated along the course of the saphenous vein. It was thought that the pulmonary infarction and the thrombosis of the vein were due to septic emboli originating in the infected wound. After a stormy course in the hospital he was able to return home three months after the onset of his illness. The edema persisted in the right lower extremity from the knee to the ankle. Some slight edema also appeared in the left lower extremity, but this was not pronounced. Elastic stockings were applied and he was permitted to return to work. At present the edema is still manifest and shows no tendency to disappear. It has been suggested by commercial houses that the use of the mercury diuretics intravenously is indicated in such conditions. Will you please comment on the value of such products in the presence of obstruction to the circulation. Any other form of treatment that you can suggest will be appreciated.

M.D., New York.

ANSWER:—A septic pulmonary embolus from an infected finger is a rare occurrence; the thrombus in the lower extremity cannot be of embolic origin unless there is a patent foramen ovale between the right and the left side of the heart and then it would have to be in the arterial tree. It is more likely that during the course of infection a latent thrombophlebitis of the lower extremity developed which gave rise to a pulmonary infarct and later resulted in a manifest venous thrombosis, a not infrequent course of events.

Efforts to relieve the residual thrombophlebitic edema are most successful when begun before the onset of any fibrosis. When the edema is allowed to persist, the plasma filtering out of the blood vessels sets up a connective tissue reaction and some edema is apt to persist. At this late stage the following measures may relieve some of the swelling: restriction of fluid intake to 1,500 cc. (this includes the water content of food), and restriction of salt to 4 Gm. a day and potassium chloride

from 3 to 5 Gm. a day. During the night the edematous limbs or the entire lower end of the bed can be elevated several inches. A glycerin-gelatin cast, applied from the toes to the knee, or if necessary even to the groin, may be applied every three weeks for several months and is more effective than the elastic stocking in relieving the edema.

Mercurial diuretics relieve edema in the early stages a few days after the onset of symptoms (THE JOURNAL, April 2, 1938, p. 1075). Several months later in the presence of induration their effect is slight and temporary. Procaine block of the lumbar sympathetic chain is also quite efficient in relieving pain and edema in the acute stage but is not likely to help months or years later.

TREATMENT OF BLADDER AFTER REMOVAL OF TUBERCULOUS KIDNEY

To the Editor:—A man aged 35 who had complained of pain in the right loin and frequent urination with "burning" sensation for the past two months was submitted to a right-sided nephrectomy. He had had Pott's disease (lumbar) as a child. Preoperative examination showed that the man was apparently well nourished and not acutely ill. The blood pressure was 140 systolic, 90 diastolic. The eyes, ears, nose and throat were essentially normal. The neck showed the scar of a thyroidectomy (performed eight years before for an exophthalmic goiter and from which he made an uneventful recovery). The heart and lungs were apparently normal. The abdomen showed no tender areas or masses. The liver, spleen and kidneys were not palpable. There was right-sided infra-costal tenderness, slight but definite. The reflexes were normal. Examination of the urine showed several red blood cells per high power field and a few pus cells. Smears and guinea pig inoculation proved the presence of a right-sided tuberculous bacilluria. The left kidney showed no evidence of tubercle bacilli on repeated smears and guinea pig inoculations. Kidney function tests of both sides gave negative reactions. A flat abdominal plate showed a round area (apparently of caseation) about one-half inch in diameter at the lower pole of the right kidney. The second and third lumbar vertebrae were fused as the result of the old tuberculous lesion. There was no evidence here of any activity. The left kidney appeared normal by intravenous and retrograde pyelograms. Cystoscopy revealed three small areas of ulceration around the right ureteral orifice, apparently tuberculous in nature. X-ray films of the chest showed some fibrosis but no active lesion. Postoperative inspection of the removed right kidney showed a large tuberculous abscess (three-fourths inch in diameter) at its lower pole. The wound healed without any complications. It is the surgeon's opinion that this patient should have roentgen treatment for his bladder and injections of old tuberculin in gradually increasing doses. I would appreciate your opinion of this type of postoperative therapy. What are the chances of the ulcerations of the bladder clearing up without roentgen treatment? What are the dangers, if any, of giving old tuberculin? Do you believe old tuberculin is indicated here? What is the prognosis in this case?

M.D., New York.

ANSWER:—It is probably not necessary to use x-rays in the treatment of cases of this kind. Most of the bladders involved in this way heal without any treatment other than general measures. Local treatment was in vogue some time ago, and it sometimes kept the local symptoms going and made them worse, often increasing the pain.

There are cases presenting extensive tuberculosis of the bladder that demand treatment of one sort or another, but in these cases neither local treatment nor roentgen therapy is indicated. The use of old tuberculin in this case is probably not necessary. One should rely on plenty of rest, sunshine, nourishing food and good old fashioned cod liver oil.

ALBUMINURIA IN YOUTH

To the Editor:—A boy and a girl, both 16 years of age, unrelated, came to me for a general physical check-up. In both cases the usual routine examination revealed mild secondary anemia and marked albuminuria. The latter was determined by use of Purdy's heat test as described in the sixth edition of Todd and Sanford's Clinical Diagnosis by Laboratory Methods, page 136. Can you outline for me a procedure which I can follow in order to determine the seriousness of the condition, the prognosis and the advice which I must give these patients regarding their future activity in regard to exercise and their choice of their life's work. The boy wishes to study medicine. Would the strain of long years of study and internship and the demands of active practice be too much? The usual search for foci of infection and the more common causes for this condition revealed nothing. The past history in each case indicates that the probable origin was scarlet fever in early childhood.

Erwin Steinman, M.D., Washington, D. C.

ANSWER:—The significance of albuminuria in children as evidence of organic kidney disease must be qualified by consideration of the possibility that the proteinuria is of the harmless, though frequent, type known as juvenile or orthostatic albuminuria. This diagnosis is made by exclusion of the known organic causes of proteinuria, by the demonstration of normal renal function (concentration test, phenolsulfonphthalein test or urea clearance) and of normal urinary sediment with the exception of a few hyaline casts, and by the typical absence of protein in urine secreted during the night or while the patient is at rest

after several hours in the recumbent position. Sometimes unusual precautions must be taken to obtain protein-free urine, because even the slight activity of getting out of bed to urinate may produce proteinuria. The patient should therefore be instructed to void after going to bed at night and again before getting out of bed in the morning. Exercise, cold showers and perhaps emotional stimulation may be followed by proteinuria in some children. A lordotic posture associated with rapid growth is often a factor in juvenile proteinuria. It should be remembered, however, that all these influences may also aggravate an organic proteinuria. If after the usual diagnostic procedures there is still the slightest doubt as to the nature of the proteinuria, an intravenous pyelogram is indicated to rule out common developmental anomalies, hydronephrosis and other urologic abnormalities. At this point a urologic consultant can be useful.

The prognosis and treatment will depend on the diagnosis. If the proteinuria is of the harmless variety, the child should be considered as perfectly healthy and not restricted as to activity or diet. Nutrition should be improved if necessary and iron given to increase the hemoglobin. Correction of poor posture by simple exercises may be helpful.

There is no reason to anticipate any unusual difficulties if such a patient should enter the profession of medicine, provided he is in good general health and possesses the other qualifications of a prospective physician.

If some organic renal disease is finally diagnosed, prognosis and treatment will vary with the type of disease and the degree of functional impairment. No more definite statement can be made without further details regarding the diagnosis.

OXYGEN FOR MIGRAINE

To the Editor:—Will you please let me know the status of oxygen tanks and gas masks in the treatment of migraine?

Solomon Goodman, M.D., Brooklyn.

ANSWER:—The field of oxygen therapy has been greatly increased as the result of the ability to administer oxygen U. S. P. in the inspired air economically, efficiently and comfortably. Preliminary reports have been made by Boothby, Lovelace and Bulbulian and by Alvarez. In the report by the latter, the beneficial effect of the inhalation of oxygen U. S. P. in the treatment of migraine was first published. Boothby, Lovelace and Mayo gave further details in their paper at the recent meeting of the American Medical Association at St. Louis.

Severe headaches of the migraine type probably arise from several different causes. Boothby, Lovelace and Mayo reported that they most frequently obtained a beneficial effect when the patients had a definite prodromal period of from one to three hours' duration, if the oxygen was given during this period. Often when the oxygen was thus administered the attack was entirely aborted. Thus, in order that the method will be practicable, the patient should, under instruction from his physician, have the apparatus installed in his home so that at the first warning of the onset of the attack the inhalation of oxygen can be started.

Definite beneficial effect was less frequently obtained if administration of oxygen was not started until after the headache had fully developed and had become intense. Some of the patients who did not obtain complete relief from oxygen alone found that oxygen combined with small doses of ergotamine tartrate (gynergen) or other drug therapy was more effective than medication alone and often permitted the use of smaller amounts of drugs.

Inhalation of oxygen U. S. P. cannot be expected to be beneficial in all cases, but it seems as though it will prove to have a definite place in the treatment of migraine, either alone or in combination with drug therapy.

HEMORRHAGE IN ANTERIOR CHAMBER OF EYE

To the Editor:—Two months after a cataract operation, complicated by a severe and slowly absorbing hemorrhage in the anterior chamber only, would aspiration of the aqueous be a meritorious procedure in order to expedite earlier visual acuity? Has such a postoperative procedure been utilized and if so by whom and with what results?

C. B. Greear, M.D., Honaker, Va.

ANSWER:—Puncture of the anterior chamber and aspiration of the blood are of value only when the blood is still fluid. After two months the probability is that extensive coagulation has taken place and that simple puncture of the anterior chamber would be useless; the clot would have to be grasped with forceps and pulled out. Such postoperative procedure has been in use for more than half a century and is discussed at length by Elschnig in the section on surgery in the second edition of Graefe-Saemisch.

CHRONIC SUPPURATIVE MASTOIDITIS

To the Editor:—A patient who had left chronic mastoiditis was operated on about seven years ago for the first time. The ear continued to discharge thick pus. Two years ago another operation was performed, at which time the ossicles were removed from the ear and the mastoid was again cleaned out. Since the second operation the mastoid wound heals, especially during the summer, and only a few drops of pus is discharged through the auditory canal. During the winter months pus forms behind the mastoid scar, which later breaks down, and pus is discharged through the mastoid wound as well as through the auditory canal. Of what value would irrigations and compresses of urea solution be in such a condition? Where may I find references on the subject?

M.D., Pennsylvania.

ANSWER:—With the information given, it is not easy to answer this query. If the patient had chronic mastoiditis at the time of the first operation it is not quite clear why the ossicles were not removed from the ear at the first operation, because this is part of the classic mastoid operation for chronic suppurative otitis media.

There are a number of possibilities to explain the recurrence of the discharge from the mastoid wound and from the external auditory canal. A small amount of mucoid secretion should not be considered as due to a failure of the operation if there are no other symptoms. The improvement of symptoms during the summertime with their exacerbation in the wintertime might mean that frequent head colds were reinfecting the eustachian tube, which was not completely closed at the time of the operation. There is also the possibility that there are some peritubal cells which become infected in the wintertime, but this is less likely. Finally, there may also be some cells in other portions of the petrosal pyramid which discharge from time to time, although this type of involvement would be apt to be more constant throughout the year. All of these could exist even if it is assumed that the second operation was technically complete. Compresses of urea solution would probably do little good. Irrigations with a urea solution could be tried empirically and might be effective. As a further aid in the diagnosis, one could make x-ray films of the petrosal portions of the temporal bone and even use iodized oil, which could possibly be made to enter cellular structures by filling the external auditory canal and then using compression by means of a Politzer bag.

TRAUMATIC ARTHRITIS WITH CALCIFICATION

To the Editor:—A woman aged 30 bumped her right elbow against a wall early in January 1939 and thereafter noted a progressive periarticular swelling with pain, increased heat and redness and limitation of motion. Some six weeks to two months later the arm was up in fairly acute flexion, no extension being possible because of extreme pain, and the skin was tight and glistening because of the swelling. The temperature varied from 97 to 98.6 F. by mouth. The white blood count remained at about 10,000 and there was a slight hypochromic anemia. General symptoms such as anorexia, headache and nausea were present but not marked. The first week in April a fairly definite collection of fluid was palpated about the joint, most of it lying medially, and aspiration revealed it to be red bloodlike fluid containing clumps of fibrin. Culture was taken but no report has as yet been made. The next day the pocket of fluid was opened widely and a soft rubber drain was inserted. This resulted in some recovery of function and definite improvement with respect to general swelling and pain, even though not as much fluid was encountered as had been expected. At the present time the patient is feeling fairly well, is eating well and has but little pain. However, x-ray examination yesterday revealed an area of calcification in the soft tissue medial to the joint, about 3 inches by 3 inches, conforming to the size and position of the fluid pocket mentioned, and this is apparently growing larger. She is not able to extend the forearm as far as she could after the pocket was opened. What is the *modus operandi* of the pathologic changes here was opened. What further treatment would you advise? Does the fact found and what further treatment have any bearing on the case? Your explanation of the pathology involved and suggestions for treatment will be greatly appreciated. Incidentally, a search for foci of infection has been entirely negative and she had no upper respiratory or other infections previous to onset. She is the mother of two children and her Wassermann reaction is negative, although she admits that she has had two miscarriages during the last four years, both occurring at about the second month.

Bernard J. Voss, M.D., Columbia, Utah.

ANSWER:—If trauma to the right elbow is followed by periarticular swelling and pain, as well as local inflammation, but a rise in temperature or leukocytosis is absent, the inference would be that injury to the soft tissues had taken place and fluid, possibly bloody fluid, had collected. Moreover, calcification may have taken place in the fluid with resultant stiffness and limitation of motion. The fact that an incision was made and bloody fluid drained forth, but that pus was not encountered, would

support this inference. It is best to wait until complete calcification has occurred before any surgical procedure, including excision, is carried out. Such treatment, before calcification has become complete, usually tends to aggravate the condition. As a rule, roentgenographic examination from four to six months after injury will reveal that the condition is well demarcated, and then excision can be performed. In some instances flexion deformity of the capsule may be present and occasionally capsulotomy is indicated. Pregnancy may have an effect on the condition, since it may influence the degree of calcification.

Application of moderate heat may relieve some of the local pain but massage in such a condition is inadvisable.

NOCTURNAL NECK PAIN

To the Editor:—A patient has pain in the lower occipital area nightly. He states that this pain has been constant every night for the past five years. He is never troubled during the day or evening and retires at night perfectly normal, falls to sleep easily and remains so until about 4 a. m., when he awakens from a sound sleep with a sharp, piercing pain in the region of the junction of the vertebrae and the skull, and sometimes the pain involves the first three or four vertebrae. The pain has always been in this particular area. He is compelled to get out of bed, and after walking around and massaging this area for a period of from fifteen to twenty minutes all symptoms disappear and he remains comfortable until the ensuing night. He advises me that about five years ago he had an ordinary stiff neck on arising in the morning and went to a chiropractor for adjustment. He received one treatment with no beneficial results and felt that his stiff neck was worse. These pains have been recurring daily ever since. He is 58 years of age and is normally healthy. The Wassermann reaction of the blood is negative; the differential blood count is normal, the red blood and white blood counts are normal and urinalysis is negative. X-ray films of the skull and vertebrae in different views are all negative and neurologic tests are all negative. The man has been under my care for the past two years and various treatments have been tried with no results. If you have any suggestions as to what this may be or any treatment, I would be very much obliged.

M.D., Wisconsin.

ANSWER.—The fact that the pain comes on during sleep suggests that it is due to relaxation of the muscles of the neck. This always suggests tumor of the spinal cord, although this may or may not be the correct diagnosis; at least this diagnosis should be checked by a Queckenstedt test or perhaps injection of iodized oil if the neurologic examination reveals nothing.

ETHYL CHLORIDE OR CHLOROFORM AS INDUCTION AGENTS FOR ETHER

To the Editor:—During the last eight years of my experience in anesthesia I have administered more than 200 anesthetics. In most of them the anesthesia used has been ether with ethyl chloride as the induction agent. I have had no fatalities directly attributable to the anesthesia while the patient was in the operating room. On three or four occasions I have had to give artificial respiration during the induction stage with ethyl chloride. On at least two occasions I have had to give short artificial respiration during the second stage with chloroform. I have practiced respiration in a small city in which there is only one hospital. The Sister in charge of the hospital condemned the use of ethyl chloride entirely. The use of ethyl chloride as an induction agent to anesthesia has never been condemned by the medical staff of this hospital. From my experience I have found ethyl chloride to be of a valuable induction agent and a much more rapid one than chloroform, when given carefully in small amounts. Still, the Sister of the hospital forbids me to use ethyl chloride as an induction agent. She advocates chloroform instead. I might add that gas machines are not available. Is ethyl chloride too dangerous to use as an induction agent when carefully given in small amounts? Do you condemn its use entirely?

M.D., Indiana.

ANSWER.—In the majority of hospitals, those who are qualified to be members of the staff are usually considered responsible for the choice of drugs to be administered.

As ethyl chloride and chloroform are both halogen derivatives of alcohol and are characterized by similar pharmacologic hazards, the use of either as an induction agent for ether anesthesia must be based on the ability, experience and judgment of the anesthetist.

ORANGE JUICE AND BAKING SODA

To the Editor:—Please discuss the rationale of mixing in a little soda with orange juice when given to infants. Is there any reason at all for doing this?

M.D., Texas.

ANSWER.—Orange juice contains citric acid, but it is not necessary to neutralize this weak organic acid by adding sodium bicarbonate. Because of its mineral composition, orange juice, although acid in taste and in reaction, is alkaline in the body. Large amounts of orange juice tend to make the urine alkaline. It is unnecessary to add sodium bicarbonate to orange juice, although if the juice is sour a little sugar may be added.

Medical Examinations and Licensure

COMING EXAMINATIONS

SPECIAL BOARDS

Examinations of the Special Boards were published in THE JOURNAL, September 23, page 1247.

STATE AND TERRITORIAL BOARDS

ALABAMA: Montgomery, June 18-20. Sec., Dr. J. N. Baker, 519 Dexter Ave., Montgomery.

ARIZONA: Phoenix, Oct. 3-4. Sec., Dr. J. H. Patterson, 826 Security Bldg., Phoenix.

ARKANSAS: Basic Science, Little Rock, Oct. 23. Sec., Mr. Louis E. Gebauer, 701 Main St., Little Rock. Medical (Regular), Little Rock, Nov. 9-10. Sec., Dr. D. L. Owens, Harrison. Medical (Eclectic), Little Rock, Nov. 9-10. Sec., Dr. Clarence H. Young, 1415 Main St., Little Rock.

CALIFORNIA: Written examination, Sacramento, Oct. 16-19. Oral examination (required when reciprocity application is based on a state certificate of license issued ten or more years before filing application in California), San Francisco, Nov. 15. Sec., Dr. Charles B. Pinkham, 420 State Office Bldg., Sacramento.

COLORADO: Endorsement, Denver, Oct. 3. Examination, Denver, Oct. 4-6. Sec., Dr. Harvey W. Snyder, 831 Republic Bldg., Denver.

CONNECTICUT: Basic Science, New Haven, Oct. 14. Prerequisite to license examination, Address State Board of Healing Arts, 1895 Yale Station, New Haven. Medical (Regular), Examination, Hartford, Nov. 14-15. Endorsement, Hartford, Nov. 28. Sec., Dr. Thomas P. Murdock, 147 W. Main St., Meriden. Medical (Homoeopathic), Derby, Nov. 14-15. Sec., Dr. Joseph H. Evans, 1488 Chapel St., New Haven.

DELAWARE: Examination, Dover, July 9-11. Reciprocity, Dover, July 16. Sec., Medical Council of Delaware, Dr. Joseph S. McDaniel, 229 S. State St., Dover.

DISTRICT OF COLUMBIA: Basic Science, Washington, Oct. 23-24. Medical, Washington, Nov. 13-14. Sec., Commission on Licensure, Dr. George C. Ruhland, 203 District Bldg., Washington.

FLORIDA: Jacksonville, Nov. 13-14. Sec., Dr. William M. Rowlett, Box 786, Tampa.

GEORGIA: Atlanta, Oct. 10-11. Joint-Sec., State Examining Boards, Mr. R. C. Coleman, 111 State Capitol, Atlanta.

HAWAII: Honolulu, Oct. 9-12. Sec., Dr. James A. Morgan, 48 Young Bldg., Honolulu.

IDAHO: Boise, Oct. 3-4. Dir., Bureau of Occupational License, Mr. H. B. Waitlesley, State Capitol Bldg., Boise.

ILLINOIS: Chicago, Oct. 17-19. Acting Superintendent of Registration, Department of Registration and Education, Mr. Lucien A. File, Springfield.

INDIANA: Indianapolis, June 18-20. Sec., Board of Medical Registration and Examination, Dr. J. W. Bowers, 301 State House, Indianapolis.

IOWA: Basic Science, Des Moines, Oct. 10. Dir., Division of Licensure and Registration, Mr. H. W. Grefe, State Department of Health, Capitol Bldg., Des Moines.

KANSAS: Topeka, Dec. 12-13. Sec., Board of Medical Registration and Examination, Dr. J. F. Hassig, 905 N. 7th St., Kansas City.

KENTUCKY: Louisville, Dec. 5-7. Sec., State Board of Health, Dr. A. T. McCormack, 620 S. Third St., Louisville.

MAINE: Portland, Nov. 14-15. Sec., Board of Registration of Medicine, Dr. Adam P. Leighton, 192 State St., Portland.

MARYLAND: Regular, Baltimore, Dec. 12-15. Sec., Dr. John T. O'Mara, 1215 Cathedral St., Baltimore. Homeopathic, Baltimore, Dec. 12-13. Sec., Dr. John A. Evans, 612 W. 40th St., Baltimore.

MASSACHUSETTS: Boston, Nov. 14-16. Sec., Board of Registration in Medicine, Dr. Stephen Rushmore, 413-F State House, Boston.

MICHIGAN: Lansing, Oct. 11-13. Sec., Board of Registration in Medicine, Dr. J. Earl McIntyre, 100 W. Allegan St., Lansing.

MINNESOTA: Basic Science, Minneapolis, Oct. 3-4. Sec., Dr. J. Charnley McKinley, 126 Millard Hall, University of Minnesota, Minneapolis. Medical, Minneapolis, Oct. 17-19. Sec., Dr. Julian F. Du Bois, 350 St. Peter St., St. Paul.

MISSISSIPPI: Reciprocity, Jackson, December. Asst. Sec., State Board of Health, Dr. R. N. Whitfield, Jackson.

MISSOURI: Kansas City, Oct. 26-28. Sec., State Board of Health, Dr. Harry F. Parker, State Capitol Bldg., Jefferson City.

MONTANA: Reciprocity, Helena, Oct. 2. Examination, Helena, Oct. 3-4. Sec., Dr. S. A. Cooney, 216 Power Block, Helena.

NEBRASKA: Basic Science, Lincoln, Oct. 3-4. Medical, Lincoln, Nov. 24-25. Dir., Bureau of Examining Boards, Mrs. Clark Perkins, 1009 State Capitol Bldg., Lincoln.

NEVADA: Written examination and reciprocity with oral examination, Carson City, Nov. 6. Sec., Dr. John E. Worden, 311 W. Robinson St., Carson City.

NEW JERSEY: Trenton, Oct. 17-18. Sec., Dr. Earl S. Hallinger, 28 W. State St., Trenton.

NEW MEXICO: Santa Fe, Oct. 9-10. Sec., Dr. Le Grand Ward, 135 Sena Plaza, Santa Fe.

NORTH CAROLINA: Reciprocity and Endorsement, Raleigh, Dec. 11. Sec., Dr. W. D. James, Hamlet.

NORTH DAKOTA: Grand Forks, Jan. 2-5. Sec., Dr. G. M. Williamson, 4½ S. Third St., Grand Forks.

OKLAHOMA: Basic Science, Oklahoma City, Nov. 6. Sec. of State, Hon. C. C. Childress, State Capitol, Oklahoma City. Medical, Oklahoma City, Dec. 13. Sec., Dr. James D. Osborn, Jr., Frederick.

OREGON: Basic Science, Portland, Oct. 28. Sec., State Board of Higher Education, Mr. Charles D. Byrne, University of Oregon, Eugene.

PENNSYLVANIA: Philadelphia, January. Dir., Bureau of Professional Licensing, Dr. James A. Newpher, Department of Public Instruction, 358 Education Bldg., Harrisburg.

RHODE ISLAND: Providence, Oct. 5-6. Sec., Board of Examiners in Medicine, Dr. Robert M. Lord, 122 Waterman Ave., Providence.

SOUTH CAROLINA: Columbia, Nov. 14. Sec., Dr. A. Earle Boozer, 505 Saluda Ave., Columbia.

SOUTH DAKOTA: Pierre, Jan. 16-17. Dir., Medical Licensure, Dr. G. J. Van Heuvelen, State Board of Health, Pierre.

TEXAS: Austin, Nov. 20-22. Sec., Dr. T. J. Crowe, 918-19-20 Mercantile Bldg., Dallas.

UTAH: *Reciprocity and Endorsement*. Salt Lake City, Oct. 10. Dir., Department of Registration, Mr. G. V. Billings, 324 State Capitol Bldg., Salt Lake City.

VERMONT: Burlington, Feb. 13-15. Sec., Board of Medical Registration, Dr. W. Scott Nay, Underhill.

VIRGINIA: Richmond, Dec. 13. Sec., Dr. J. W. Preston, 30½ Franklin Road, Roanoke.

WEST VIRGINIA: Fairmont, Nov. 6-8. Sec., Public Health Council, Dr. Arthur E. McClue, State Capitol, Charleston.

WISCONSIN: Madison, Jan. 9-11. Sec., Dr. Henry J. Gramling, 507 Mariner Tower, Milwaukee.

WYOMING: Cheyenne, Oct. 2. Sec., Dr. M. C. Keith, Capitol Bldg., Cheyenne.

New York Endorsement Report

Mr. Herbert J. Hamilton, chief, Bureau of Professional Examinations, reports 165 physicians licensed by endorsement from February 15 through July 15, 1939. The following schools were represented:

School	LICENSED BY ENDORSEMENT	Year Endorsement Grad. of
College of Medical Evangelists.....	(1935), (1938) N. B. M. Ex.	(1937) California
Stanford University School of Medicine.....	(1937) N. B. M. Ex.	California

Book Notices

Malaria in Panama. By James Stevens Simmons, B.S., M.D., Ph.D., Lieutenant Colonel, Medical Corps, U. S. Army, with the collaboration of George R. Callender, M.D., Lieutenant Colonel, Medical Corps, U. S. Army, Dalfres P. Curry, M.D., Major, Medical Reserve Corps, U. S. Army, Seymour C. Schwartz, B.S., M.D., Dr. P.H., Lieutenant Colonel, Medical Corps, U. S. Army, and Raymond Randall, D.V.M., Lieutenant Colonel, Veterinary Corps, U. S. Army. The American Journal of Hygiene Monographic Series, No. 13, January, 1939. Supported by the De Lamar Fund of The Johns Hopkins University. Cloth. Price, \$1.10. Pp. 326, with 32 illustrations. Baltimore: Johns Hopkins Press, 1939.

It is particularly opportune in the field of public health and preventive medicine that a complete account of the history and present status of malaria and malarial control at Panama should be written and that members of the Medical Corps of the United States Army should write it. It was here that General William Crawford Gorgas and his associates demonstrated that a great engineering enterprise need not fail even in the fever-stricken tropics if adequately provided and skilfully administered sanitation and medical service were supplied. Army organization, a vision of the problems, and medical and sanitary skill mastered malaria on a gigantic scale. Though whipped, malaria is rarely, if at all, completely vanquished. In the tropics, at least, the fight goes on continuously and ground gained is quickly lost when economy cuts down resources. Lieut. Col. J. S. Simmons writes the history of malaria on the Isthmus of Panama (1501-1938), Major D. P. Curry and Lieutenant Colonel Simmons describe malaria in the Panama Canal Zone (1904-1938) and Lieutenant Colonels Simmons, G. R. Callender, S. C. Schwartz and Raymond Randall give an account of malaria in the military forces of the Panama Canal Zone (1911-1938). The rainfall, aquatic environment and primitive culture of the natives in Panama afford ideal conditions for anopheline mosquitoes and the maintenance of plasmodium infections in man. From the earliest records of Spanish occupation malaria has impeded progress. It defeated all efforts at the construction of the transisthmian canal until it was held at bay. Since 1904 the records of the Panama Canal show that the incidence of malaria has greatly decreased in the sanitated cities of Panama and Colon, but surveys for the detection of human carriers and the experience of the U. S. Army in the field reveal the persistence of a high prevalence of malaria elsewhere in the republic of Panama. The morbidity in the Canal Zone decreased from 821 per thousand in 1906 to 16 in 1916, and subsequently rates have varied between 11 and 31. The increased efficacy of medical service is indicated by the fact that the death rate from malaria decreased from 8.7 in 1906 to 0.16 in 1914 and since that date only eighteen employees have died of malaria.

The large reservoir of human malaria carriers existing among the Negro farmers in the Canal Zone has not been reduced by free medication offered to persons found on recurrent monthly examinations to be carriers, possibly because the treatment is not sufficiently effective. Destruction of breeding grounds of anopheline mosquitoes by permanent sanitation for from 1 to 3 miles around towns and posts in which employees of the canal organization live has not prevented anophelines capable of long flights from entering the sanitated area from outside breeding grounds.

The incidence of malaria among United States troops maintained in Panama since 1911 has varied. It was highest, 208 per thousand, in 1914. The mean annual rates from 1916 to 1926 and from 1927 to 1935 were 81.5 and 65.9 respectively. For 1936 and 1937 it was only 39.4 and 40.6. The incidence of malaria in troops in Panama has always been considerably higher than among similar troops stationed elsewhere. It has been more prevalent on the Atlantic than on the Pacific side. The highest hospital admission rates occur at posts nearest unsanitated areas, and the lowest at those near large sanitated regions. The incidence falls in the dry season and is highest in the first half of the rainy season. It is also higher among troops than among employees, because of greater exposure of the former. Spectacular outbreaks have occurred during field maneuvers. Carriers are detected in and around military posts, and infected anophelines are present even in buildings during a large part of the year. More effective therapeutic treatment is needed.

No less than thirteen species of anophelines live in Panama, of which at least eleven are actual or potential vectors of malaria. The general conclusion of the whole matter is that better prophylactic methods are needed for the protection of troops in the field and more effective and less expensive procedures for the prevention of malaria among the inhabitants of the American tropics.

Die Herzkrankheiten: Klinik, Röntgenbild und Elektrokardiogramm. Von Dr. med. Paul Uhlenbrück, a. o. Prof. an der Universität Köln/Rhein. Second edition. Paper. Price, 36 marks. Pp. 422, with 413 illustrations. Leipzig: Johann Ambrosius Barth, 1939.

As in the first edition, the author has maintained the excellent manner of presentation. The number of illustrations and pages have been increased by a third. The author has enlarged the section on roentgenkymography and has added data concerning this method in various parts of the book. A section on the theory of the electrocardiogram as recently presented by Schellong has been revised, and sections have been added on the use of the vectordiagram and on the heart in diabetes. The part dealing with the electrocardiogram in left and right axis deviation has been expanded. The section on diseases of the coronary artery has also been greatly expanded and has been separated from that on heart failure. An attempt has been made to outline the appearance of the chest leads in this condition. While this section is a great improvement over the last, several of the diagrams used, such as figures 21 and 22, are fallacious, and it would have been better to use original curves rather than line diagrams to show the electrocardiographic contour in coronary disease. In the case reports more electrocardiograms with chest leads would have been valuable. The addition of several tables summarizing the electrocardiographic appearance in various types of heart disease was a great improvement. A new section dealing with the therapy of heart disease has been added and in it are given detailed tables of diets. A section dealing with functional tests of the circulation has also been added, and this is extremely valuable since it has been a much neglected subject in textbooks heretofore. Otherwise the text has been left almost unaltered. The book can be highly recommended to physicians interested in heart disease in showing the field of usefulness of the x-ray and electrocardiographic methods of studying the heart. The expert will find it useful in obtaining the present point of view of the German school. The attempt to enlarge the clinical side of the text in this edition may turn out to be more of a disadvantage than an advantage.

The General Tissue and Humoral Response to an Avirulent Tubercle Bacillus Including Growth Characteristics of the Organism. By Sol Roy Rosenthal, M.D., Ph.D., Associate in Bacteriology and Public Health. Joint Contribution from the Tice Laboratories of the City of Chicago Municipal Tuberculosis Sanitarium and the College of Medicine of the University of Illinois. Illinois Medical and Dental Monographs, Vol. II, No. 2. Cloth. Price, \$3. Pp. 184, with 80 illustrations. Urbana: University of Illinois Press, 1938.

This monograph, primarily on BCG (*Bacillus Calmette-Guérin*), was written to determine whether a general cellular reaction of the tissues and the blood to the tubercle bacillus exists and, if so, what component of the antigen is responsible for the reaction. To this end, both the irritant and the irritated were examined to determine their variabilities and reactions. Obviously the literature on tuberculosis has not been completely reviewed because of its extensiveness, but the author has chosen sufficient bibliography to make the subject matter authoritative.

In the introduction, the organism and host factors are evoked to display the reticulo-endothelial system as having an important place in immunity, being especially prominent in its counteraction to the tubercle bacillus. Other cellular systems may also be of great import in immunity, but microscopic alterations in them are not detectable. A cycle of reproduction is noted for BCG if conditions are suitable, with sprouting of granules and non-acid fast stages described in chapter II. On the basis of animal inoculation, dissociation of BCG in the sense of increased virulence did not occur. Changes in the structure of colonies did transpire, but they were more or less transitory and probably associated with an arrest or acceleration of growth of the organism. The addition of crude BCG phospholipins, egg lecithin, cholesterol or neutral fats to

mediums on which BCG was grown caused variations in the structure of the colonies of the bacillus which reverted. No increase in virulence of BCG was noted. Intracardiac injection of BCG caused not only a specific reaction, with the formation of tubercles in various organs, but also a generalized histiocytic response. This generalized reticulo-endothelial response was ascribed to "submicroscopic" forms of the tubercle bacillus. The formation and regression of the tubercle were traced. The blood picture reflected the tissue response. The number of bacilli and the organs involved determined to a large extent the proliferative or exudative character of the nodule. In chapter VI a line of reasoning is begun which might raise serious objections from those who do not subscribe to the view of ultramicroscopic or submicroscopic filter passing forms of the tubercle bacilli. The author was able to recover viable bacilli from animals although the antecedent organs failed to demonstrate positive cultures. These results (readily open to criticism) suggested the presence of submicroscopic forms and were thought to account for the stimulation of the reticulo-endothelial system. The term "submicroscopic" is defined as "forms that may evade detection because of their similar staining properties to the tissues. It does not necessarily imply forms too small to be seen by the microscope, although such forms are included." Such a definition can only lead to future confusion of the problem and rather weakens than strengthens the stand for BCG. Future researches must be more exacting on this point. In chapter VII the submicroscopic form is again called on as a poor defense for oral administration of BCG. Finally, chapter IX contains a summary; suggestive evidence is presented to indicate that elements of the tubercle bacilli not discernible microscopically are present in the organs of animals inoculated intravenously, intradermally and orally with mature forms of the organism. These forms can be recovered only after serial inoculation into animals. It is believed that they may be responsible for the generalized response of the reticulo-endothelial system. Whether or not the elements of the tubercle bacillus referred to are merely their granular constituents or true "ultraviruses" is not known. The inconclusiveness of this part of the author's work suggests a continuance of the search for superior and more exact weapons to solve this phase of the problem. In no wise does it detract from the tremendous value of this monograph, which not only presents the author's personal studies on BCG but also gives valuable evidence of the validity of the contentions by the French school that BCG is a "virus fixe" in the general sense.

The monograph is well printed on an excellent grade of paper chosen to do justice to the many half tone illustrations. The style of presentation of material and its order is also pleasing, even though many detailed experiments are cited. Although a truly scientific monograph written for the specialist on tuberculosis, it can be recommended to any physician interested in medical progress and investigation. The University of Illinois and editorial committee are to be complimented for making this monograph available at an extremely modest sum. Its scientific and educational value warrant their confidence.

Sleep, Your Life's One Third. By Maurice Chidekel, M.D., With a foreword by Robert Victor Seliger, M.D., Visiting Psychiatrist Johns Hopkins Hospital. Cloth. Price, \$2. Pp. 183. New York: Saravan House, Publishers, 1939.

In this book the author offers to laymen his divers views and experiences. The style is clear and the quotations from many poets are copious. Many and various are the topics discussed, for example "the first authentic occurrence of murder by a sleep walker"; somnolence, which the author states is bought on mostly by the patient himself and which unfortunately "in quite a number of cases is followed by the catastrophic disease known as narcolepsy"; the vividness of certain dreams, as illustrated by a woman who swore she had sex relations with an angel; the Freudian view which the author outlines and accepts that "if the father is suffering from sleeplessness, the girl with father attachment is sure to be afflicted with the same trouble." It is difficult to say just how the author classifies the causes of insomnia, but they seem to include schizophrenia and other psychotic states; "organic wakefulness"

due, for instance, to cancer of the prostate; pain, dyspnea; advanced kidney disease; anemia; "psychic sleeplessness, the commonest of all," such as follows an emotional shock or fear and excitement; toxic sleeplessness, resulting from overuse of alcohol and tobacco, as well as from tea and coffee, and sleeplessness due to digestive disturbances. The author evidently believes that insomnia is due to "afflux of blood in the brain." Regarding the "conquest of insomnia," he offers divers suggestions, including the treatment of any underlying disease discovered. The method which he seems to recommend most for general use is "light self hypnosis," after the method of Diethelm. Since the early nineties, various methods of "light self hypnosis" have been employed from time to time in this country for the treatment of sleeplessness. They have never proved popular among physicians. Among the reasons for this unpopularity probably is the failure of the method to apply suitably to the average patient. Psychologists also commonly condemn methods of self suggestion, often under the view that the remedy is worse than the disease.

Herz- und Kreislauferkrankungen in ihren Beziehungen zum Nervensystem und zur Psyche: Eine Einführung für Nervenärzte und Internisten. Von Dr. med. H. D. von Witzleben, Chefarzt des Sanatoriums Kreischka bei Dresden. Boards. Price, 4.50 marks. Pp. 101. Leipzig: Georg Thieme, 1939.

It is typical of the times that attempts should be made to correlate factors in internal medicine with the realm of neuropsychiatry. This the author has attempted to do as far as disturbances of the heart and circulation are concerned. He presents the current teachings in Germany as represented by some of the leading internists and psychiatrists. For the reader interested in obtaining such information this booklet is of value. Unfortunately, little reference is made to the work done in other countries; one has the feeling that much of what the author has to say is citation of authority. The reviewer is left with the impression that the subject is rather superficially considered. The material is divided into the following headings: (1) innervation of blood vessels, (2) blood supply and nerve supply of the heart, (3) tonus of the heart, (4) theory of nerve action, (5) cerebral circulation, (6) high altitude and compression, (7) blood pressure regulators (moderator nerves), (8) cardiovascular epilepsy, (9) cardiac cataplexes, (10) effect of changes of the psyche on the circulation and (11) circulatory psychoses and (12) the "nervous heart." Larger print should have been used and a bibliography appended.

Appendicitis: A Statistical Study. By Matthew Young and W. T. Russell. Medical Research Council Special Report Series, No. 233. Paper. Price, 30 cents; Is. Pp. 64. New York: British Library of Information; London: His Majesty's Stationery Office, 1939.

Much of the data in this statistical report were obtained from published sources; of the thirty-six tables presented, a little more than half are original, comprising general data from England and Wales and more detailed material from three large London hospitals. The aim of the study as quoted in the preface was to obtain information "as to the factors which may influence the mortality." While such factors are mentioned as the marital state (single women are more likely to die of appendicitis than married ones), one looks in vain for detailed data which may have a therapeutic application, e. g. material on the question of delayed operation in appendicitis, which is uppermost in the minds of many physicians. The only suggestive data on this question are contained in the comparative mortality rates from the London, St. Thomas's and University College hospitals. The last named, where immediate operation was the rule, reported by far the lowest mortality. In the other two hospitals a certain percentage of the patients were apparently treated along the delayed lines. The statistics indicate that appendicitis is on the increase in England and Wales, although the most conclusive data are contained in one table of figures from Scotland, where the incidence increased 23 per cent between 1930 and 1935 while sickness from other causes during this period remained the same. The reader would have more confidence in drawing inferences from these last figures if they applied only to acute appendicitis; a statement that they do cannot be found. Obviously, if chronic appendicitis is included, the

value of statistical inferences is greatly weakened. Another point brought out in the report is the fact that the mortality rate in England and Wales has not increased in spite of the apparently increased incidence. Though the authors have not discussed this interesting and important feature in detail, one may dig out of table 18 a probable reason: fewer patients now enter the hospital with a ruptured appendix. In two London hospitals between 1900 and 1909, 1,772 cases of abscess and peritonitis were recorded, whereas between 1920 and 1929 but 1,264 such cases were listed, in spite of the fact that the total number of cases was nearly double in the later decade.

Recent Advances in Obstetrics and Gynecology. By Aleck W. Bourne, M.A., M.B., B.Ch., Obstetric Surgeon to St. Mary's Hospital, London, and Leslie H. Williams, M.D., M.S., F.R.C.S., Senior Obstetric Surgeon to Out-Patients, St. Mary's Hospital, London. Fourth edition. Cloth. Price, \$5. Pp. 366, with 98 illustrations. Philadelphia: P. Blakiston's Son & Co., Inc., 1939.

An interval of seven years has elapsed between the appearance of the third edition and the present one. In this book the authors have included information concerning practically all the important advances made in obstetrics and gynecology during the past few years. In the section on obstetrics the subjects discussed are antepartum care, antepartum hemorrhage, breech deliveries, pyelitis, cesarean section, anesthesia and analgesia and puerperal sepsis. It is gratifying to see that antepartum care is receiving the important consideration which it deserves. Likewise cesarean section, particularly when combined with blood transfusion for the treatment of placenta praevia, is accorded an important place. In the treatment of pyelitis, mandelic acid and sulfanilamide are included. The authors are not convinced of the superiority of the cervical cesarean section over the classic one, but the only cesarean section they illustrate is the cervical one with a transverse incision in the lower uterine segment. The chapter on analgesia and anesthesia includes a discussion of practically all present day analgesics and anesthetics. In the treatment of puerperal sepsis, sulfanilamide is of course given special consideration. In the section on gynecology the subjects discussed are cancer of the uterus, sterility, prolapse, leukorrhea, sympathectomy, the sex hormones, ovarian tumors, the use of x-rays and physical therapy. The authors describe the technique and results of operation and radiation therapy for cancer of the cervix in various parts of the world. For the correction of prolapse they illustrate the Manchester operation, which is rapidly gaining in popularity, the interposition operation and the Mayo-Ward vaginal hysterectomy. The chapter on the sex hormones is brief and to the point. The chapters on ovarian tumors, the use of x-rays and physical therapy were written by Wilfred Shaw, H. Courtney Gage and Justina Wilson respectively. At the end of the book are special chapters on the Kielland forceps and the active principles of ergot. The book is well written, and the authors are to be congratulated on the selection of the material which they consider advances in obstetrics and gynecology.

Physiology of the Uterus with Clinical Correlations. By Samuel R. M. Reynolds, M.A., Ph.D., Associate Professor of Physiology, Long Island College of Medicine, Brooklyn, N. Y. With forewords by George W. Corner, M.D., Professor of Anatomy, University of Rochester School of Medicine and Dentistry, Rochester, N. Y., and Robert T. Frank, M.D., F.A.C.S., Consulting Gynecologist, Mount Sinai Hospital, New York. Cloth. Price, \$7.50. Pp. 447, with 44 illustrations. New York & London: Paul B. Hoeber, Inc., 1939.

This monograph on the physiology of the uterus will be a welcome contribution to the many investigators and clinicians interested in the problems of reproduction. The work comprises a comprehensive summary of the literature in this field as well as an intelligent interpretation of the available data. The bibliography of 1,190 references arranged alphabetically should be a great aid to any one working in this field. The physiology of uterine motility in experimental animals as well as in the human being is thoroughly considered. Chapters are devoted to innervation of the uterus, its blood and lymph supply, its metabolism and its growth. The hormonal control of physiologic changes, motility and reproduction are described in separate chapters. The relationships of the uterus to bodily functions are considered. Lastly, a chapter is devoted to a clinical contribution on the various endo-

crime problems as related to the physiology and pathology of reproduction. The author's extensive experiences over a period of years in this special field make him qualified to evaluate the data presented. Many investigators, however, may not agree with some of his interpretations and conclusions. The clinical observations are perhaps on less secure ground than the experimental. In spite of the large number of references in the bibliography, some excellent contributions have been omitted. The forewords of Corner, a renowned investigator in this field, and of Frank, a well known gynecologist, who has made many contributions in these special fields, attest the value of this contribution. The volume can be heartily recommended to all students interested in the problems of reproduction in any of its phases.

Recent Advances in Medicine: Clinical, Laboratory, Therapeutic. By G. E. Beaumont, M.A., D.M., F.R.C.P., Physician to the Middlesex Hospital, London, and E. C. Dodds, M.V.O., D.Sc., M.D., Courtauld Professor of Biochemistry in the University of London, London. Ninth edition. Cloth. Price, \$5. Pp. 431, with 42 illustrations. Philadelphia: P. Blakiston's Son & Co., Inc., 1939.

This is an exceedingly valuable book. By no means all the matters treated are very recent, but this makes the volume more valuable because it serves to present each subject in a more thorough manner. Recent advances in biochemistry are well covered, and chemical procedures are briefly but adequately described. Advances in endocrinology are not so completely reported, but this is no doubt due to the fact that advances in this field have been so rapid that it is impossible to keep pace with them in a textbook. Recent contributions to our knowledge of virus diseases are neglected. On the other hand chemotherapy is well discussed, including the use of sulfanilamide and sulfapyridine.

Cancer: Causation, Prevention and Treatment. By A. E. Blackburn, M.D. Cloth. Price, 6s. Pp. 111, with 14 illustrations. London: H. K. Lewis & Co., Ltd., 1939.

In this treatise the author presents evidence which he believes establishes a relation between certain foods and cancer. He also emphasizes the effects of habits of modern civilization on the incidence of malignant disease. Certain clinical data are given, and a dietary treatment of cancer is suggested. Some interesting facts are noted concerning the incidence of cancer in different races. The author, who has traveled extensively, has made many personal observations in this respect. On the whole, the theories and conclusions, while interesting, will not withstand critical analysis and the student of this disease will ask for more convincing evidence before accepting the author's views on the cause and treatment of cancer.

Kurzgefasstes Lehrbuch der Psychiatrie. Von Professor Dr. Johannes Lange. Third edition by Dr. August Bostroem, Professor der Psychiatrie und Neurologie in Leipzig. Paper. Price, 7.20 marks. Pp. 276, with 4 illustrations. Leipzig: Georg Thieme, 1939.

Professor Lange, who recently died, leaves this edition of his brief textbook of psychiatry, which has been edited by Bostroem. It is a compendium which contains descriptive material of most of the usual psychiatric conditions in the orthodox kraepelinian fashion. Several works published in the United States are considerably better than this volume. In fact, its sterile descriptiveness without any dynamic or modern ideas tends to make it much less valuable than available American textbooks.

Belträge zur psychiatrischen Erblehre auf Grund von Untersuchungen an einer Inselbevölkerung. Von Erik Strömberg. Acta Psychiatrica et Neurologica, Supplementum XIX. Denne Afhandling er af det lægevidenskabelige Fakultet antaget til offentlig at forsvares for den medicinske Doktorgrad, København. Paper. Pp. 259. Copenhagen: Ejnar Munksgaard, 1938.

The author has studied the inheritance of psychiatric conditions in the Danish island of Bornholm, which he finds particularly suited for studies of an isolated group. He finds that the expectancy for schizophrenia is 0.65 ± 0.05 per cent and for manic-depressive insanity 0.36 ± 0.04 per cent. These figures are more or less typical of those published by other experimenters. There seems hardly any evidence to suggest that schizophrenia is not recessive and manic-depressive insanity dominant in their characteristic inheritance, according to the author of this statistical monograph.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Malpractice: Death of Diabetic Patient Following Withdrawal of Insulin by Drugless Healer; Manslaughter.—The defendant, Karsunky, was described in the record as a drugless healer but he had no license to practice in the state of Washington. He was charged in an information (1) of the crime of homicide growing out of the death of a diabetic patient resulting from the defendant's improper treatment and (2) of the misdemeanor of practicing medicine without a license. Having waived a trial by jury, he was found guilty by the court on both charges and appealed to the Supreme Court of Washington.

The patient, before he came under the defendant's treatment, was a strong, robust man, 33 years old, and engaged in heavy manual labor. For a period of three years he had had diabetes and had been a patient of Dr. Edgar Anderson, who prescribed a strict diet which regulated the intake of carbohydrates and required the patient to take every day about 15 units of insulin. By this treatment the patient was enabled to go about his work in the usual manner. The defendant, apparently an itinerant practitioner, stopped regularly at a certain hotel and prescribed for persons who called at his room. The medicines he prescribed were prepared by some company outside of the state and sold by the defendant in the original package to his patients. He used the title "doctor" in connection with his literature, labels and diet sheets and in making appointments with persons desirous of consulting him. On Dec. 11, 1937, the patient called on the defendant in the latter's hotel room and placed himself under his care. The defendant gave the patient no physical examination but did interrogate him. The patient informed the defendant of his diabetic condition and that he desired to discontinue the use of insulin. The defendant told the patient that he could cure diabetes, that his medicine would cure it but that his medicine and insulin would not mix. He advised the patient to discontinue the use of insulin and, in lieu of the strict diet prescribed by Dr. Anderson, the defendant gave the patient a new diet list which did not regulate the intake of carbohydrates. The defendant testified in the case that his reason for advising the patient not to take insulin was "because insulin is not human—it is not fit for any dog." That afternoon, the patient called on Dr. Anderson but did not advise him that he was under the care of the defendant. Dr. Anderson examined the patient and found he was in "grand condition" and "sugar free." On that date, the patient discontinued the use of insulin.

Two days later, the patient received by mail the medicines prescribed by the defendant and commenced to take them according to the directions sent with the medicines. On December 18, the patient was too ill to go to work and on the following day, December 19, he was confined to his bed and complained of feeling numb all over. On Monday, December 20, the patient's wife called in Dr. Anderson, who found the patient in a serious condition. He advised that the patient be placed in a hospital but the patient refused to go. That night, however, the patient was removed to a hospital and on his arrival was placed under an oxygen tent, given dextrose and saline solution with about 40 units of insulin. A blood sugar test was made but "the blood sugar report was so high that night that the physician could not get a reading." The next morning, the patient slipped into a comatose condition and during the day more insulin was administered to him. He died that evening. The autopsy disclosed that his death was due to diabetic coma.

The defendant contended that the evidence was not sufficient to sustain conviction on either count. But, the court pointed out, the practice of medicine includes the advice, whether oral or in the form of a written prescription, of a physician to his

patient as to what to do or what the patient should refrain from doing. Diagnosing, prescribing, orally or in writing, and treating ailments are constituent parts of practicing medicine. If one is so engaged, or holds himself out as being so engaged, he is guilty of violating the medical practice act if at the time of so doing he does not have a license authorizing him to practice medicine and surgery.

If the proximate cause of the patient's death, the court continued, was the advice and treatment given by the defendant, unless the patient's death was justifiable or excusable, the defendant is guilty of manslaughter. There was evidence that the medicines prescribed by the defendant were, under the medical practice act, drugs or medicinal preparations. The evidence was conclusive that the medicines prescribed and sent to the patient had little, if any, therapeutic value; their only effect on the patient was psychologic. The evidence was overwhelming, however, that the defendant's treatment of the patient's diabetic condition—giving him a diet list under which he was permitted to partake of unlimited quantities of carbohydrates and at the same time inducing the patient to discontinue the use of insulin—would inevitably cause the patient's death. The administration of such treatment by the defendant was through gross ignorance of the art he assumed to practice.

Five physicians testified that the only known and accepted treatment of diabetes mellitus is by the use of a restricted carbohydrate diet and the use of insulin, depending, of course, on the severity of the disease, and that to induce the patient to abstain from the use of insulin in view of "a case of his standing" would be the same as "signing his death warrant," as he absolutely could not live without taking insulin. There was no testimony, other than that of the defendant, contradicting the testimony of these physicians. When the defendant, the court continued, prescribed for the patient and attempted to treat him for the diabetes, without having a license to do so, he was engaged in an unlawful act. He was grossly negligent in furnishing a diet list that permitted the patient to eat unrestricted quantities of carbohydrates and at the same time advising and inducing the patient to dispense with the use of insulin. Prior to the time the defendant commenced to advise and treat the patient, the condition of the latter for three years under the treatment of a skillful physician had improved. The properly controlled carbohydrate diet and the use of insulin had resulted in the patient's being sugar free and permitted him to take care of his affairs in life just like any other man. The defendant assumed to treat the patient for diabetes mellitus, therefore he was bound to know the nature of the remedies he prescribed and also the treatment he adopted, and he is criminally responsible for the death resulting to the patient from gross ignorance in the application of the treatment.

The weight of authority is that criminal negligence exists where a physician or person assuming to act as such exhibits gross lack of competence. Criminal negligence may arise from failure to give proper instructions to the patient, or the giving, as in the present case, of improper instructions. To induce the patient to refrain from the use of insulin, which was necessary to preserve his life, is in principle the same as withholding the insulin from him by physical force. Whether by strength of mind or by physical power the defendant prevented the patient from using insulin, the principle is the same.

The defendant's counsel contended that the proximate cause of the patient's death was the failure of Dr. Anderson, when called to the patient's home December 20, properly to treat the patient who was then lapsing into a state of diabetic coma. But, the court said, there was no evidence from which a jury would be authorized reasonably to conclude that the patient's death resulted from anything that Dr. Anderson failed to do. Furthermore, if a person unlawfully inflicts on the person of another a wound calculated to endanger or destroy life, it would not be a defense to a charge of unlawful homicide, where death ensued, to show that the wounded person might have recovered if the wound had been more skillfully treated. Even unskillful or negligent treatment of the wound on the part of the wounded person or his physicians, which may have aggravated the wound and contributed to the death, does not

relieve the assailant from liability. The court again emphasized the fact, however, that there was no showing that the treatment by Dr. Anderson on December 20 and 21 was the cause of the patient's death.

The court's attention was invited to a pamphlet, which was not offered in evidence, published by a manufacturer of insulin. Counsel for the defendant in his oral argument and in his brief quoted liberally from the pamphlet to support his theory that Dr. Anderson's failure "promptly to institute the precise treatment" needed when coma developed was the proximate cause of the patient's death. The rule is, the court said, that facts which are universally known, and which may be found in encyclopedias or dictionaries, are judicially noticed, provided they are of such universal notoriety and so generally understood that they may be regarded as forming part of the common knowledge of every person. The court refused, however, to take judicial notice of the facts in the pamphlet referred to. The pamphlet, standing alone, was not competent proof of the statements contained in it.

Under the law of Washington, a person charged with the commission of a crime may not waive trial by jury unless in his plea he admits the truth of the charge or in open court confesses his guilt. Not only is there an absence of statutory authority to waive trial by jury, but the right to waive, except in the two instances noted, is taken away. In the present case, the Supreme Court held that the defendant could not waive his right to a trial by jury and that because he was not given a trial by jury the judgment of the trial court must be reversed. The case was remanded with directions to the trial court to grant a new trial.—*State v. Karsunky (Wash.)*, 84 P. (2d) 390.

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1929 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Air Embolism Complicating Artificial Pneumothorax.—

Schattenberg and Ziskind believe it quite probable that air embolism as a complication following artificial pneumothorax is more frequent than is generally recognized. This may be due to the fact that, if a fatal termination does not occur, the condition is overlooked, called pleural shock or else this type of case is not reported in the literature. The infrequency of necropsies on patients dying from air embolism and the definite proof of the cause of death in the case that they report, the authors believe, warrants its recording. At necropsy air emboli were found in the left side of the heart, coronary arteries and cerebral vessels, and were observed clinically in the retinal vessels. No pneumothorax was found although five refills had been given. However, the amounts of these were small. The pleural cavity was entirely obliterated and one might assume that the air was administered into the air spaces within the lung. Barnwell states that this must be the case in many inductions. In the last and fatal insufflation the air was most likely administered into one of the pulmonary veins, thus causing air embolism. The pressures found at the start of the refill tend to strengthen this conclusion. A diseased lung or pleura is necessary in the pathogenesis of this condition. When the lung is fibrotic and diseased, and this is the type of case in which air embolism usually occurs, the vessels are held stationary and are prevented from retracting or collapsing. Air introduced into a pulmonary vein or a blood vessel within adhesions, which establishes anastomoses with the pulmonary circuit, will travel to the left side of the heart and then into the general arterial circulation. There are three main theories as to the cause of death from air embolism. They are cerebral, respiratory with suffocation from the obstruction of the pulmonary artery, and cardiac the result of the lowering of intracardiac pressure and circulatory failure. The clinical symptoms will depend on that part of the body within which the air embolus lodges. In most cases giddiness, faintness, tickling of the throat, queer feelings or the coughing up of blood will be complained of. The patient may become pale or go into coma, and occasionally sudden death will occur. Splotching of the skin, transient blindness, diplopia, nystagmus, cyanosis, shock, profuse perspiration, chills, cardiac irregularity and respiratory failure may also be noted.

Primary Cancer of Gallbladder.—Liebowitz reports twenty-eight cases of primary carcinoma of the gallbladder. Twenty-three of the cases occurred in women. This confirms previous observations that, like gallbladder disease in general, carcinomatous involvement predominates in women. The average age of the patients was 64.1 years. That calculi may be concerned in the genesis of the growth is indicated, as stones occurred in 71.4 per cent of the cases reviewed. The fundus and neck of the viscus are the most frequent sites of origin. Pathologically, the series consisted of fifteen scirrhous, eight papillary and three colloid adenocarcinomas and two epidermoid carcinomas. In one of the latter, typical prickle cells and nests of epithelial pearls were present. Carcinoma of the gallbladder spreads principally by contiguity, by the lymphatics, by way of the blood stream and also by way of peritoneal transplantation. The liver is most frequently implicated by secondary growths. Despite the rarity of skeletal involvement, metastases occurred to a lumbar vertebra. Splenic metastasis was observed once. Pain was the most frequent and constant symptom and was present in 67 per cent (nineteen) of the cases, in seventeen of which calculi were associated. A mass was noted in 60 per cent of cases and jaundice of the obstructive type in 46 per cent. Rapid weight loss was a significant observation. The cases have been characterized by a high incidence of surgical complications. Operative results have been ominous; in only one of sixteen surgical cases was there a possibility of cure. Carcinoma of the gallbladder is an insidious disease, eludes early diagnosis and is usually recognized in its later stages, when surgical extirpation is not feasible. Prophylactic removal of gallbladders containing calculi has been advocated.

Differentiation of Shock from Hemorrhage.—Moon points out that the evidence from a review of the records of hemoconcentration or acute erythrocytosis indicates that hemoconcentration is related etiologically to the mechanism by which the syndrome of shock develops in various clinical conditions. Most of the authors attributed the hemoconcentration to the leakage of plasma through endothelium which had been rendered abnormally permeable by some injurious agent or condition. The author's experimental studies have included intraperitoneal introduction of muscle, liver and other tissue substances, injections of watery extracts of normal tissues, of bile and its salts, peptone, bacterial cultures and toxins, histamine, snake venoms and drugs such as emetine, barbital and the barbiturates. They also included burns, trauma, intestinal manipulation and obstructions, and the effects of proteins in sensitized animals. Regularly, and without exception, the agents and conditions mentioned produced hemoconcentration. This appeared early, and its degree was proportional to the apparent illness of the animal. When recovery followed, the blood returned to its normal composition. When death resulted, the postmortem observations were characteristic of shock. It appears that any agent or condition which affects capillary endothelium adversely will produce the syndrome of shock if that effect is produced systemically or in extensive visceral areas. Both the experimental and the clinical observations indicate that hemoconcentration is the surest and earliest clinical sign of endothelial damage of sufficient extent or degree to impair the efficiency of the circulation. It is strange that a phenomenon which is so grave in its import, so common in

its occurrence and so easily demonstrated has not been utilized by physicians in their clinical studies of patients. Its use as a clinical test facilitates the early recognition and treatment of shock.

Louse and Trachoma Virus.—With the possibility in mind that trachoma is a rickettsial disease, it seemed likely to Braley that the louse should be considered as its vector, since trachomatous patients frequently are infested with these insects. He obtained head lice from patients with active trachoma. Approximately 8 per cent of lice are reported to harbor rickettsias in the gastrointestinal tract, but less than 1 per cent of the lice found by the author on American Indians contained rickettsias. A few smears showed extracellular collections of rickettsia-like bodies, but no intracellular collections were found. Mostly staphylococci were present in the smears. When ground lice were cultured on blood agar mediums only *Staphylococcus albus* grew. No bodies could be found that simulated the Halberstädter-Prowazek bodies or initial bodies of trachoma. Conjunctival epithelial smears of patients from whom the lice were obtained contained typical Halberstädter-Prowazek inclusion bodies. In none of the twenty eyes of baboons inoculated with ground lice from trachomatous patients did conjunctivitis develop. The material transferred from the conjunctiva of the same patients produced an active experimental trachoma in baboons. Six of the ten inoculated chick embryos died. Smears showed only staphylococci and degenerated cellular debris. Smears from the inoculated areas of the four embryos that lived showed young connective tissue cells, epithelium from the chorio-allantoic membrane and louse debris. No rickettsias were found. Sections of the chorio-allantoic membrane showed moderate hyperplasia of the epithelium at the site of inoculation but no evidence of rickettsias. Twenty lice were given intrarectal inoculation of known trachomatous material. In none of the five baboon eyes inoculated with these lice did conjunctivitis develop; however, the material used for injection produced experimental trachoma in a baboon.

Familial Retinal Degeneration, Detachment and Cataract.—Friedman observed over a period of several years a mother and seven children who presented a set of clinical manifestations which to his knowledge are unique in ophthalmology. These clinical data pertain first to the skeletal system and secondly to the eye proper. All the offspring except the oldest (female) bear a remarkable resemblance to the mother, who has the facies common to hyperpituitarism. All members of the family except the oldest child have myopic astigmatism. All the visible fundi are affected by a peculiar form of peripheral retinal degeneration, and in all but two of the children so affected there have occurred either complicating cataracts or retinal detachments or both. There is one exception: the oldest child has normal fundi. Examination of the fundi of these patients showed that the lesions were located in the extreme periphery. The lesions of the fundus began in the periphery and progressed slowly inward, but not far. The central two thirds

of the retina appeared free from pathologic changes. The vitreous in all cases in which it could be studied was degenerated and contained freely movable opaque strands. The family tree indicates the complications in the members of the series. A history of trauma to the eye or head antedated the detachments in three of the children. The violence of the injury was not severe, indicating the predisposition of such eyes to traumatic detachments of the retina. The author has no means of knowing how early in life the retinal lesions make their appearance, as all the patients were adults.

Nasal Allergy in Children.—In order to arrive at an accurate diagnosis and to obtain better results in the management and treatment of many nasal complaints in children, Barnett and Carnahan state that both the rhinologist and the pediatrician must become allergy conscious. To determine nasal allergy in childhood and to determine whether or not the allergy is complicated by infection, physicians need to perform routine examinations of the nasal secretions. Allergic control is vital if indicated surgical procedures are to be of benefit. Removal of infected tonsils and adenoids may aggravate symptoms in a child with uncontrolled allergy. Even though surgical intervention is indicated by x-ray or clinical observations, the results will be disappointing if associated allergy is not simultaneously or previously relieved. Removal of nasal polyps in the patient with uncontrolled allergy may be followed by prompt recurrence. Cytologic examinations of the nasal secretions with predominance of eosinophils offer confirmatory evidence of allergy. Local treatment for nasal allergy must be conservative. Prophylactic allergic measures are often sufficient to give relief from nasal allergy. Allergic testing and hyposensitization may be reserved for unrelieved or complicated conditions.

Acute Infection of Circumvallate Papilla.—According to Waldapfel, little is known about acute inflammations of the papillae of the tongue. These infections are usually included with diseases of the mucous membrane of the tongue and are not separated from the various types of glossitis. Such isolated infections occur and they offer diagnostic difficulties. The various papillae of the tongue offer a variety of conditions for the harboring of infectious organisms. He cites a case of infection of a circumvallate papilla, with retention and abscess formation, extreme pain on swallowing, intense pain of the tongue when touched, and coating of the tongue and the oral mucous membranes. Every severe process of this kind, the author points out, should be regarded as an isolated infection of a circumvallate papilla and its own related identical serous gland, which appears as a unit embryologically, anatomically and pathologically. The mode of infection is not known; perhaps injuries through foreign bodies in the food may play a part. The diagnostic difficulties arise mainly in the beginning of the disease and are due to the thick coating on the tongue and adjacent areas of the mucous membrane, which covers the port of entry of the infection and the diseased area. This coating develops especially easily when the patient is not eating normally. Several points aid in making the differential diagnosis: Extreme tenderness of the tongue is manifest at the slightest touch without evident reason. The tongue is movable and apparently not greatly swollen, and the floor of the mouth is free from infection. The base of the tongue is free from involvement and there is no laryngeal edema

present. The temperature is only moderately high. The prognosis is good. Heat (ultrashort wave diathermy) and antiphlogistic applications break down the papilla and spontaneous discharge results; if the condition is of long duration and fluctuation of the tongue is discernible, a superficial incision is advisable.

Goiter in Saskatoon.—According to Binning, 166 cases of goiter (6.7 per cent) were found in 2,451 Saskatoon public school children. While age, sex, race and the social status were undoubtedly factors in the etiology, the source of water seemed to be the deciding factor. As adequate water analysis was not possible, some figures are presented showing that infected water (sterile or nonsterile), rather than the iodine content, was responsible for the occurrence of goiter. Severity seemed to be dependent to some extent on the source of water, those with slight goiters having a higher percentage of running water than those with moderate and large goiters.

Control of Bleeding Tendency in Jaundice.—During the last two years Smith and his colleagues observed about sixty cases of biliary tract disease, in most of which jaundice, together with a varying degree of prothrombin deficiency, was present. A number of these cases have been reported, and from the unreported group they cite four cases that illustrate a number of the problems which commonly arise. Evidence is reviewed to show that of patients with obstructive jaundice or biliary fistulas the bleeding tendency, so commonly observed, is due to faulty absorption of a fat-soluble vitamin, vitamin K. By suitable administration of this vitamin the bleeding tendency can be corrected, eliminating one cause of the high mortality in the surgical treatment of these patients. In order to determine the degree of vitamin K deficiency and to gauge the dosage of vitamin to be administered it is necessary to know the plasma prothrombin level, for the determination of which the authors describe a simple bedside test. Purified preparations of vitamin K may be safely administered intravenously in cases in which nausea and vomiting preclude oral administration. The test to determine the plasma prothrombin level is carried out in a small serologic test tube of approximately 3 cc. capacity (75 by 10 mm.). Into the tube is placed 0.1 cc. of fluidextract of

thromboplastin. The tube is then filled up to the 1 cc. mark with freshly drawn blood. To obtain prompt mixing of the blood and thromboplastin the tube is inverted once over the finger and is then tilted gently every second or two in order that the beginning of clotting may be observed. In the case of normal blood, clotting occurs within twenty-five to thirty seconds; but, if the prothrombin level is low, the clotting time may be prolonged to several times this figure. By using normal blood as a standard control the patient's prothrombin activity may be expressed in terms of the normal standard. The following formula will be found suitable: Prothrombin activity (in percentage of normal) equals the clotting time of normal blood divided by the clotting time of the patient's blood multiplied by 100. The only technical feature in the entire procedure is the preparation of the thromboplastin solution. Fresh lung tissue (ox or rabbit) is cut into fine pieces and to each 10 Gm. of tissue 10 cc. of physiologic solution of sodium chloride is added. The mixture is stirred occasionally for the next two hours, after which it is strained through several layers of gauze. The pinkish opalescent fluid thus obtained is the thromboplastin used in the foregoing test. It keeps well for several weeks in the ice box or better still in the frozen state.

Bacillary Infections of Urogenital Tract.—Sandholzer and Scott made a study of the aerobic, gram-negative bacilli in 530 cultures recovered from 283 patients with infections of the genito-urinary tract. The aim of the investigation was to ascertain whether or not any relationship between the type of organism and the clinical course of the infection could be found. The bacteria fell into six genera. Members of *Escherichia* occurred in 83 per cent of the cultures (twenty-seven species or types) and members of *Aerobacter* in 13 per cent (fourteen species or types), while the remaining 4 per cent were distributed among the genera *Proteus*, *Salmonella*, *Shigella* and *Pseudomonas*. When specimens of urine from the same individual were cul-

tured at intervals over a period of months, the type of organism recovered remained constant as to species and type of hemolysis, in some instances, but in other instances variations in either one or both of these factors occurred. Thus, from one patient nine different species belonging to three genera were recovered at various times. The author states that a larger series of cases than his will have to be studied before final statements concerning the reaction to therapy of individuals infected with the various types of bacteria are justified. However, his study does suggest that there may be a considerable variation in response to therapy. Thus, 66 per cent of the patients infected with *Escherichia coli* responded favorably to treatment. Of these, 78 per cent of the infections due to the beta hemolytic type and 80 per cent of those due to the gamma hemolytic type were cured, while only 66 per cent of the patients with non-hemolytic types responded well. On the other hand, only 38 per cent of the patients with infections due to *Escherichia communior* and 42 per cent of those infected with strains of *Aerobacter* were cured. Only 28 per cent of the patients with infections due to *Proteus* were cured.

Staphylococcus Food Poisoning.—Thirty-one cases of staphylococcus food poisoning are discussed by Caudill and Humphrey. On questioning the patients they found that one of two foods emanating from one establishment had been eaten by all of them: either hollandaise sauce or a cream sauce in which hollandaise sauce was used. Clinically the cases varied from fairly mild to extremely severe gastro-enteritis. In the severe cases there were persistent vomiting, cramps, profuse diarrhea and alarming prostration. One person had a blood tinged diarrhea and was so prostrated and dehydrated that intravenous sodium chloride and dextrose were thought necessary. In this case and in the others, the acute enteritis was over within eight hours and subsequent recovery was rapid and uneventful. Culture of a specimen of the hollandaise sauce revealed an almost pure culture of hemolytic staphylococcus, both aureus and albus. The cook stated that the sauce had been made about 8 o'clock in the morning and then used throughout the day. The cream sauce was served hot, illustrating the relative stability of the toxin to heat.

Aloes in Treatment of Burns and Scalds.—Crewe presents a method of treating burns and scalds which eliminates infection and waiting for the separation of the coagulum. He employs an ointment of which the active ingredient is socotrine, or Barbados aloes. The ointment is made by mixing 8 Gm. of the powdered aloes and about 8 Gm. of liquid petrolatum in an ounce (30 Gr.) of white petrolatum jelly. If liquid petrolatum is not used the ointment is a little too stiff. The usual preliminary precautions with regard to contamination and infection are taken. Blisters are carefully protected and the serum is evacuated with a hypodermic needle, after which enough mercurochrome is injected to cover the base of each collapsed vesicle. When this preliminary treatment has been completed, sterile gauze is folded in about four thicknesses to make an area large enough to cover the burn. The gauze is laid on a smooth, sterile towel and is covered with a layer of ointment at least one-eighth inch thick. This dressing is laid, ointment side down, on the burned area. More gauze may be placed on this dressing and the whole held in place with bandages or other material. No attempt should be made to spread the ointment on the burn, because it will not adhere readily to the raw surface. Ordinarily this dressing is not removed for two days. At the end of that time the entire dressing can be removed easily. There is no sticking from dried serum or dried blood. The surface of the wound does not bleed but has a clean, glazed appearance, as if the area were covered with a thin, transparent film. Unless new blisters have formed, another dressing, prepared as before, is applied and each dressing is left in place for two days. Usually, only from four to six dressings of aloes ointment will be required; after this zinc stearate or some other bland dressing may be applied. Cutaneous surfaces soiled by the ointment can be cleaned with benzine and the residue can be removed with rubbing alcohol. Aloes, used either as the leaf or the ointment, possesses distinct analgesic qualities. Dense, white scar tissue is not seen after healing of burns treated with aloes but the burned areas are reddish at first and remain smooth and pliable. Healing is rapid. Aloes possesses some enzymotic action; pus is apparently digested, for purulent surfaces become clean. The drug is astringent, possibly because of the tannin it contains. It has styptic properties in fresh cuts, when applied as a powder. Antiseptic properties are indicated by the rapid clearing up of infected surfaces. It might be feared that absorption would give rise to unpleasant effects, but none have been observed. Stools have not been loose in any case. No undesirable effect was seen when powdered aloes was dusted full strength, daily for a number of days, over the entire surface of large, chronic ulcers.

Dermatitis Caused by a New Insecticide.—Schwartz and Warren assert that while their report shows that alpha naphthyl isothiocyanate, base of a new insecticide, is a primary cutaneous irritant and a sensitizer, it is not recommended that its manufacture be permanently discontinued, because nearly all insecticides are cutaneous irritants or sensitizers, and when workers come in contact with new insecticidal preparations (as in this instance) dermatitis is likely to develop. It is the general experience that they can be safely manufactured under proper working conditions. However, before this new insecticide is placed on the market, actual experiments should be performed as to its effect on the skin of those who may be exposed to its action when it is sprayed, according to directions, in an enclosed room to destroy insects. Such tests can be made by spraying the insecticide containing alpha naphthyl isothiocyanate in a closed room in which a group of persons are exposed to its action for fifteen minutes a day for at least ten days and observed for ten days more. If one case of dermatitis should develop among 200 persons thus exposed, the product should not be placed on the market. If, as a result of such an experiment, it is decided to continue the manufacture of alpha naphthyl isothiocyanate, it is recommended that the manufacturing process be totally enclosed. Directions on cans of all insecticides should be worded in such a manner as to impress on the consumer the fact that the contents are toxic and irritating to the skin unless they are used according to directions. This would place the emphasis on their toxicity and tend to make people more careful in using them. The placing of poison labels on all insecticides would safeguard not only the health of the consumer but also the financial interests of the manufacturer by helping to protect him against law suits.

- Socialized Hospitals, a Threat. H. A. Black, Pueblo, Colo.—p. 565.

Surgical Treatment of Epilepsy.—Stuck suggests that many chronic epileptic patients, when studied carefully, will be found to have definite operative cerebral lesions. These focal lesions, which are varied in nature, are so situated that they

are irritating to the cortex. In some cases the lesion is a contracting scar from an old compound skull fracture; in others it is a tumor, an abscess, an old encephalitis, meningitis, a hemorrhage or the like. In order to determine the character and location of the focal lesions, a carefully taken history, with special reference to the sequence of events in the attacks, as well as an encephalogram or ventriculogram, is essential. It may even be necessary for the physician to place the patient under observation in the hospital and to produce a few attacks in order that they may be accurately observed. Overfunction of the cerebral cortex usually results in an epileptic fit or convulsion. When there is a widespread disturbance such as a toxemia, the convulsion is generalized from the onset. Occasionally, however, the patient does not lose consciousness or have a generalized convulsion, although he may develop a generalized convulsion later. In such a case it not infrequently happens that the patient experiences an initial localized movement or sensation, known as an aura or hallucination, which is followed by a spread of this impulse over the body like a ripple across a pool of water, until the whole body is affected, consciousness is lost and a major convulsion ensues. The most valuable study of the seizure is made in the period before consciousness is lost. By intimate questioning at this time it is possible to identify the manner of onset of the attack and to localize grossly the cerebral focus. The initial event in the convulsion "signatures" the focus and is therefore the most important bit of information in the history. This "signature" may be manifest by a numbness, a tingling or a feeling of deadness of the finger, the hand or the foot; by a local weakness, a hallucination of smell, taste, odor or sight, as shown by flickering of lights, or by a temporary inability to speak.

Antipellagric Action of Certain Acids.—Bills and his associates used either pyrazine-2, 3-dicarboxylic acid or pyrazine monocarboxylic acid in the treatment of the glossitis of twenty-three pellagrins. Within two to twelve hours after the administration of the acid, the patients reported a great increase in sense of well being and relief from glossitis. Rapid fading of the glossitis was evident on objective examination. Of the six patients for whom therapy was discontinued after the glossitis disappeared, who remained on their usual inadequate diets, the symptoms reappeared within two weeks in each instance. Each of these patients was treated as before and responded in an identical manner. In general, the clinical response following the oral administration of either acid is similar to that following

the administration of adequate amounts of nicotinic acid. In contrast to nicotinic acid, these two pyrazine compounds do not produce the vasodilator symptoms which often follow the use of large doses of nicotinic acid. The maximal and minimal dosages for oral use have not been determined, but a total of from 500 to 800 mg. of either pyrazine-2, 3-dicarboxylic acid or pyrazine monocarboxylic acid, administered in divided doses from five to eight times a day, is safe and effective. The authors state that further studies are in progress to determine the therapeutic usefulness of these new agents in comparison with the established remedies for pellagra.

Clinical Use of Stilbestrol.—Karnaky believes that since the advent of diethyl stilbestrol it is no longer necessary to fight and wrestle with children who have a vaginal discharge or gonorrheal vulvovaginitis. Tablets of this estrogenic substance have a sweet taste and are pleasant to take orally. The child likes to take them because they are pink and resemble candy. It is no longer necessary to give injections or insert suppositories or give sulfanilamide, which is toxic to these children. The synthetic estrogenic diethyl stilbestrol can be used in all cases in which natural estrogen has been used. Functional uterine bleeding can be stopped more quickly by the injection of 5 mg. of diethyl stilbestrol than in the time required to take a patient to a hospital and to prepare her for and perform the dilation and curettage. The best tolerated and most effective dose is 0.1 mg. two or three times a day by mouth after meals or the whole dose at bedtime. Patients become tolerant to diethyl stilbestrol. In all the author states that he has treated, with this drug, twenty-five cases of amenorrhea, sixty of the menopause, sixteen of senile vaginitis, sixty of menometrorrhagia, eleven of hypomenorrhea, two of painful pelvis, five of vulvovaginitis, five normal women and five of complete abortion.

Prognosis of Malignant Goiter.—Ward shows the relationship of prognosis to the microscopic picture in seventy-seven of eighty-four cases of malignant goiter in which pathologic studies are available. It was found that papillary carcinoma offers a better prognosis than any other form of malignant tumor of the thyroid. The degree of the malignant condition can apparently be estimated for a given tumor by the extent of its departure from the papillary pattern; the greater the extent of this departure, the more malignant the tumor and the prognosis is thereby equally grave. The study suggests that a favorable outcome can be anticipated only in the papillary form (46 per cent) and the malignant adenomas (24 per cent). The presence of diffuse infiltration by polymorphonuclear leukocytes is of grave prognostic import in any malignant tumor of the thyroid, regardless of its pathologic pattern.

Drug Treatment of Hyperpiesia.—Evans and Loughnan observed the effect of thirty-three often used preparations on the blood pressure and symptoms of seventy patients with hyperpiesia (essential hypertension). The preparations were various and included nitrites, iodides, sedatives, xanthine and choline derivatives, vegetable extracts and hormones. Each medicament was prescribed in optimal doses for test periods of a fortnight, and at the end of each period the patient was reexamined, when the blood pressure was recorded under the same unvarying and standard conditions and any change in symptoms was noted. Control test periods were instituted for each patient, when an inert placebo mixture was the only treatment given. After allowance had been made for the tendency to obtain high blood pressure readings at the first and possibly at the second examination, and for the natural variation, and when the results from the tested drugs were compared with those from a placebo, the authors found that none of the thirty-three preparations produced hypotensive effects in patients with hyperpiesia. With regard to symptomatic improvement, only six of the drugs (bismuth subnitrate, iodine and iodide, bromide, soluble phenobarbital, potassium thiocyanate and a preparation of theobromine and phenobarbital) on an average relieved symptoms rather more than did the placebo. The sedative drugs seemed to have value in temporarily relieving nervous symptoms when these were prominent. These negative results, the authors state, should not have any bearing on the management of hypertensive heart disease including heart failure, when drug treatment can often be seen at its best. Their negative results with drugs in uncomplicated hyperpiesia do not make it less desirable that the patient should remain under medical supervision. It is obvious that a patient should not regard his symptoms as closely related to the height of his blood pressure. Medical attention must be devoted to the alleviation of symptoms when they arise and to correcting faults in living, and particularly to the adoption of timely active measures when symptoms or signs of heart failure first appear. Time will show whether surgical measures are a practicable means of lowering blood pressure and of lessening symptoms in hyperpiesia. Meantime a clearer insight into the origin of hypertension must precede its successful treatment with drugs.

Treatment of Experimental Tuberculosis with Sulfonamide Derivatives.—Birkhaug states that the parenteral daily injection of a sulfonamide derivative seems to exert a significant inhibitory action on the development of a bovine tubercle bacillus

infection of guinea pigs. The inhibitory action appears to be referable to the in vivo bacteriostatic effect of sulfonamide derivatives on the growth of the tubercle bacillus. As sulfonamide derivatives exert only an incomplete bacteriostatic effect on the tubercle bacillus, further investigations should be carried out with new derivatives of sulfonamide. Such investigations are now in progress with sulfapyridine.

Gastroscopic Study of X-Ray Negative Dyspepsia.—Bulmer states that in 1,575 "gastroduodenal" cases, culled from nearly 10,000 new outpatients, an indefinite diagnosis was made in 589 instances (38 per cent). Using the Wolf-Schindler gastroscope, 147 patients with x-ray negative or inconclusive dyspepsia have been studied. In sixty-six cases no abnormality was found, but some abnormality may be present. An increasing experience of gastroscopy has made the author increasingly reluctant to accept a negative observation as significant. The contractions of the pylorus still arouse wonder, but it is tinged with apprehension when the lesser curvature of the antrum refuses to unfold itself: in one of his apparently normal cases an unseen ulcer perforated there. Other blind areas exist, and an ulcer known to be present may not be seen by the gastroscopist. The diagnosis of chronic gastritis was made in sixty cases and the author demands a gross departure from the normal before so diagnosing a case. The gastroscopic observations in the other twenty-one cases of x-ray negative or inconclusive dyspepsia were failure to make an adequate examination in nine, gastric ulcer in eight and one each of simple ulcer later shown to be an ulcer-cancer, curious abnormality later shown to be an ulcer, cancer suspected (not found at operation) and inoperable cancer. Therefore the gastroscope has proved to be of great value in the routine investigation of this type of dyspepsia. Chronic gastritis can be diagnosed with certainty only by gastroscopy, and four case histories are given to emphasize the difficulties of clinical diagnosis.

Double Injury to the Ear.—De Szentlörinczi-Liebermann and Kelemen report a case in which a woman, owing to a fall on the head from a height and the simultaneous penetration of a hairpin into the ear, sustained a double injury. The fall caused a fracture of the middle and inner ear, whereas the pin penetrating into the ear brought about a luxation of the stapes. Death occurred after three weeks. Dissection, completed by microscopic investigation of the petrous bone, showed that the opening of the oval window, caused by luxation of the stapes, was blocked by granulations. No symptoms of meningitis were observed either clinically or as a result of dissection. Death occurred because of increasing intracranial pressure caused by a hematoma in the scala posterior. This hematoma followed a rupture in the wall of the sinus and constantly increased in volume as irrepressible vomiting pressed fresh quantities of blood through the ruptured sinus. The double nature of the injury was clearly traceable on microscopic examination.

Myocardial Lesions in Endocarditis.—De Navasquez discusses only cases of subacute bacterial endocarditis due to *Streptococcus viridans*. In *Streptococcus viridans* endocarditis, pyemic abscesses in the myocardium or elsewhere are usually absent and embolic lesions, when encountered, do not usually suppurate. The author attempts to determine the characters, frequency and mode of origin of the myocardial lesions in subacute bacterial endocarditis which could be claimed to be in any way specific. The only abnormalities observed were those attributable to subacute bacterial endocarditis. These fall into two groups: (1) vascular, confined to the arteries, arterioles or capillaries and affecting either the lumen or the wall or both and (2) extravascular, consisting mainly of foci of polymorphonuclear leukocytes, with or without necrosis of the parenchyma. Myocardial lesions were encountered in nineteen of twenty cases of subacute bacterial endocarditis. These lesions develop as a result of embolism of the coronary arteries or arterioles by fragments of vegetations which vary in size and bacterial content. They are specific only in that they show evidence of embolism and polymorphonuclear cell reaction. No relation was demonstrated to the degree of cardiac failure, the heart valve affected, the character of the vegetation or the duration of the disease. In view of its ambiguity, it is suggested that the term "Bracht-Wächter body" should no longer be employed.

Pathologic Significance of Megaloblast.—Israëls studied the morphology of the erythroblastic cells obtained by biopsy from human bone marrow in hyperplastic conditions of the erythropoietic tissue and he defines the types of cells appearing. True megaloblasts occur only when the hyperplasia is the result of lack or imperfect working of the anti-pernicious anemia liver principle. In all other conditions, cells of the normoblast series are present. There are also certain primitive cells usually

present in all types of hyperplasia, the proerythroblasts and hemocytoblasts. The normal development of the erythrocytes probably proceeds from hemocytoblasts to proerythroblasts and then to normoblasts of varying degree of maturity. The megaloblasts also develop from the proerythroblasts and then follow their own line of development to mature as erythrocytes. The megaloblasts have no place in the development of normal erythrocytes in extra-uterine life; they appear only when the proper activity of the liver principle is in abeyance. So long as the liver principle is normally available, demands for increased erythrocytes, whatever their cause, are met by proliferation of cells of the normoblastic series.

Parenteral Therapy with Sulfapyridine Soluble.—Gaisford and his co-workers found that sulfapyridine in a 33½ per cent solution of sodium salt is an adequate preparation when it is advisable to use the drug parenterally. They aver that clinically it is no more toxic than sulfapyridine, is not unduly painful after injection, is rapidly absorbed and excreted, and is less likely to cause vomiting than sulfapyridine given orally. In their experience (in various pneumococcal infections) intramuscular injection is preferable to intravenous injection, as it is less liable to cause reaction and vomiting and gives an equally satisfactory concentration in the blood. It is essential that the injection be given intramuscularly and not subcutaneously, or nonabsorption and local necrosis may take place. Although they have treated only thirty-three patients so far, the results, the authors believe, appear to justify its use in selected cases, either when there is a mass infection or when sulfapyridine causes persistent vomiting. It is not intended to replace the oral preparation. A satisfactory scheme is to give from four to six injections of 3 cc. at intervals of four hours. These may be followed by smaller doses of sulfapyridine orally until the temperature falls. Such a system is less likely to cause continued vomiting in susceptible patients than the large initial dosage in general use at present. The drug may be safely given to children and babies in appropriately reduced dosages.

Cyanosis Caused by Sulfonamide Derivatives.—Since cyanosis of varying degree has been a frequent symptom following treatment with the sulfonamide group of drugs, Campbell and Morgan attempted to assess the therapeutic value of methylene blue, favorably reported on by others, in the treatment of methemoglobinemia and sulfhemoglobinemia. Four cases illustrating the value of methylene blue in pneumonia methemoglobinemia following treatment with sulfapyridine are cited. The authors state that it can hardly be argued that the results obtained in these cases were due to a natural and spontaneous remission in the severity of the cardinal symptom, because they had previously found that, when methemoglobinemia developed during treatment with sulfapyridine, the pigment could be detected in the blood four or five days after all trace of the drug had disappeared from the blood stream. It is justifiable, therefore, to conclude that methylene blue actively converts methemoglobin into hemoglobin. Methylene blue has a similar action on the methemoglobinemia produced

by the administration nitrites. The dye is active when given by mouth. It is also slowly excreted. A prolonged effect can therefore be obtained by giving it by mouth in divided doses several times a day. In view of its action in preventing methemoglobinemia and its attending cyanosis the authors suggest that it might be worth while considering the advisability of giving it as a routine along with sulfapyridine in conditions in which prolonged treatment is necessary. The efficacy of methylene blue was also tried in two cases of sulfhemoglobinemia which developed after the administration of sulfanilamide. The dye was given intravenously and orally but was without effect. It did not prevent the development of sulfhemoglobinemia when it was administered along with sulfanilamide.

Complete Freedom from Dental Caries.—In an endeavor to trace some of the grosser causal factors of dental caries, Miller and Crombie examined twenty-five children from 10 to 14 years of age with caries-free mouths and no history of caries in the permanent dentition and compared them with an equal number of children showing gross caries but similar in other respects. They found that certain factors which were apparently associated with freedom from dental caries were the following: (1) good family dental history (not apparently of such significance as good general hygiene and diet), (2) careful infant feeding, especially breast feeding, and, (3) probably above all, absence of severe illness and an early incidence of infectious fever. No difference of present economic status was demonstrable between the two groups, but a point of importance appeared to be that children with bad teeth were often the younger members of a family, whereas those with good teeth were frequently first children. In this series of cases irregular dentition and inadequate oral hygiene did not appear to exercise any unfavorable effect on the degree of freedom from caries.

Roentgen Therapy of Intracranial Tumors.—Orley reviews the results obtained in the roentgen treatment of intracranial tumors. He states that most of the gliomas are sensitive to x-rays, but the degree of sensitivity varies with the histologic type in the descending order: medulloblastoma, ependymoma, astrocytoma and glioblastoma multiforme. The oligodendroglioma is resistant to the x-rays. Of the vascular tumors, the hemangioblastomas should be treated by operation and postoperative irradiation, while the malformations should receive irradiation alone. The meningiomas are resistant tumors. The evolution of pituitary adenomas can be divided into three stages: endocrine, visual and tumoral. The endo-

crine phase should be treated with radiation, the tumoral phase with surgery and the treatment of the visual phase should be determined by the circumstances. Patients undergoing roentgen therapy should be watched closely and surgical intervention undertaken when required. The best results follow combined treatment.

Effect of Pituitary Extract on Metabolism.—Sharpey-Schafer and Schrire studied the effect of intramuscular injection of pituitary thyrotropic extract on twenty-two normal subjects without disease of the endocrine glands, three with myxedema, one cretin and nine with low basal metabolic rates but lacking the typical signs of myxedema. The twenty-two subjects (nearly every one was suffering from peptic ulcer, sciatic pain or some surgical condition) without exception showed a normal response to the injection of thyrotropic extract. Every subject, except two, complained of malaise. Headache was usual, and some tenderness was felt in the region of the neck. Every subject showed enlargement of the thyroid. The onset of symptoms was usually on the third or fourth day of injection and on ceasing injection the symptoms subsided rapidly, so that in forty-eight hours the thyroid had returned to nearly its normal size, though the pulse rate often remained rapid for several days longer. Creatine was excreted in abnormal amounts in the urine. The basal metabolic rate became elevated. Five subjects with various disorders of the endocrine system, but without evidence of thyroid disease, gave the same response as the twenty-two normal subjects when injected with thyrotropic extract. In each case the basal metabolic rate, the electrocardiogram, the blood cholesterol and the circulation time were within normal limits. The three subjects with myxedema and the one cretin showed no response to the injection of thyrotropic extract. No alteration was observed in the clinical state, the creatine excretion or the basal metabolic rate. Five subjects with a low basal metabolism responded normally to the injection of thyrotropic extract and in four (one of acromegaly) there was no response, although there is considerable evidence that they have functioning thyroids. These results the authors believe show that a reliable preparation of thyrotropic extract may be used to investigate the function of the thyroid in man. Its further use may help to clarify that indefinite group of cases which have low basal metabolic rates but lack other signs of thyroid deficiency.

Treatment of Chronic Hypoparathyroidism.—Anderson and Lyall determined the calcium and phosphorus metabolism in three cases of postoperative parathyroid deficiency, first on a high calcium diet with a relatively high phosphorus intake and then on a low phosphorus diet in which the calcium intake was maintained at the previous high level by appropriate supplements of calcium lactate. Three subjects, serving as controls, with normal parathyroid function and calcium metabolism were studied in the same way. In the three cases of parathyroid deficiency the serum calcium could be raised to and maintained at a normal level by the administration of the diet low in phosphorus together with large doses of calcium lactate. The primary importance of this reduction in phosphorus intake was illustrated in two cases in which the same or even a greater calcium intake had no effect on the depressed serum-calcium level as long as the phosphorus intake remained high. The suggested optimal level of phosphorus intake is from 0.5 to 0.65 Gm. daily, depending on the body weight of the individual. The results of the balance experiments in these cases indicate that the improvement in the blood chemistry produced by a reduction of the phosphorus intake cannot be explained by an increased retention of calcium in the body or

a loss of phosphorus from the body. The rise in serum calcium seems rather to be secondary to the fall in serum phosphorus, which in its turn appears to be the result of a diversion of phosphorus from the body fluids to some other site in the body rather than of any loss of phosphorus from the body. The amount of phosphorus excreted by the kidneys in the three cases of parathyroid deficiency on a high phosphorus intake was as great as in the three normal subjects on a similar phosphorus intake. Normal subjects have a negative phosphorus balance during the first twelve days after the phosphorus intake is reduced from 2 to 0.5 Gm. daily, the calcium intake being 2 Gm. daily throughout. Under similar conditions patients with parathyroid deficiency, unless there is complicating renal disease, remain in positive phosphorus balance, the excretion of phosphorus by the kidneys being less than that of normal subjects on the reduced phosphorus intake. Tenth normal hydrochloric acid therapy does not adversely affect the calcium balance of patients with parathyroid deficiency, provided the calcium intake is adequate and sufficient phosphorus is being given to maintain phosphorus equilibrium. The minimal dose of vitamin D necessary to raise the serum calcium to a normal level in parathyroid deficiency appears to lie between 30,000 and 45,000 international units daily. The higher dose is effective even when the phosphorus intake is not reduced. There is thus evidence of a decreased excretion of phosphorus by the kidneys in parathyroid deficiency only when the phosphorus intake is low.

Cause of Low Blood Sugar Curve in Celiac Disease.—Crawford performed the intravenous dextrose tolerance test in twelve established cases of celiac disease, eleven of which showed a typical low oral blood sugar curve. No significant difference was found between the curves in the celiac cases and curves from normal subjects; and in five cases no difference was observed between curves obtained during active and latent phases of the disease. Insulin sensitivity tests in six of the cases gave results closely similar to those obtained from six normal subjects. From these results the author concludes that there is no abnormality of intermediate carbohydrate metabolism in cases of celiac disease; and, by exclusion, it seems certain that the low blood sugar curve of celiac disease must be due to delayed or defective absorption of carbohydrate from the intestine. This conclusion is presumably applicable to other forms of idiopathic steatorrhea as well as to celiac disease.

Note on Coincidence of Human Kala-Azar and Canine Leishmaniasis with Cutaneous Lesions in a Household. E. A. Ho.—p. 566.

Taenia Infection.—Wu points out that the stool examinations of 56,286 patients, done at the Parasitological Laboratory of the Peiping Union Medical College, revealed 337 cases positive for Taenia infection, giving a percentage of 0.6. The Taenia species was not determined in 153 cases, in 156 cases Taenia saginata was found and in the remaining twenty-eight cases Taenia solium. The relative frequency of Taenia solium to Taenia saginata was 1:5.6. Among the twenty-eight cases of intestinal infection of Taenia solium, seven cases were reported as presenting also a somatic infection with Cysticercus cellulosae, and two of these showed cerebral cysticercosis. The Taenia infection rate was higher in males (224) than in females (113). The youngest patient with Taenia infection was a child of 1 and the oldest was 76 years of age. The infection was highest among the students and lowest in farmers and children. The infection rate of foreigners in China was, so far as could be judged, only slightly lower than that of the Chinese. The majority of the patients came from the vicinity of Peiping. However, it seems that Taenia infection occurs in all parts of China.

Electrocardiogram of Patients with Hypertension. R. Lévy.—p. 730.

B₁ Hypovitaminosis and Cardiopathies in Chronic Alcoholic Addicts.—Bickel demonstrates that in a large number of patients with chronic alcoholism there exist circulatory disorders independent of all valvular, vascular or renal disorders. These disturbances consist chiefly of tachycardia, cardiac irritability, dyspnea of effort, dilatation of the heart, arterial hypotension and occasionally acute asystole. They are accompanied by only slight anatomic lesions and can be considered, at least in their first phases, as purely functional disturbances. The author presents a series of arguments which indicate that the cardiovascular disturbances of patients with chronic alcoholism may be caused by a deficiency of vitamin B₁. This deficiency of vitamin B₁ is due partly to the diminution in the total food intake of alcoholic addicts and to the impairment of their digestive tract, which hinders the normal absorption of certain alimentary substances. It is due even more to the considerable augmentation of the requirements of vitamin B₁ on the part of the organism of alcoholic addicts in comparison with the healthy organism. Vitamin therapy is likely to produce favorable effects on the cardiac disturbances of alcoholic addicts. These results are entirely comparable to those obtained in alcoholic polyneuritis. However, whereas the effects of the vitamin therapy are rapid and complete when the cardiovascular disturbances are recent, they are no longer obtainable in the old cases in which definite organic changes have replaced the functional and reversible changes of the early stages.

54: 145-288 (Aug.) 1939

- Microsporadic Hyperthyroidism. A. Jentzer.—p. 145.
*Attenuated Pancreatitis. J. Meyer-May.—p. 174.
Ligation of Carotids in Dissection of the Neck for Cancer. M. Bérard and M. Dargent.—p. 197.
Amputation of a Stenosing Tumor of the Rectum. Guillermo.—p. 211.

Attenuated Pancreatitis.—According to Meyer-May, there were admitted to the Surgical Clinic of the Medical School at Hanoi (French Indo-China) in the period of 1936 to 1938 inclusive twenty-seven cases of acute nonhemorrhagic pancreatitis. This type of pancreatitis, termed by Delbet "attenuated pancreatitis," differs from the acute hemorrhagic type in a tendency to recurrent attacks and to chronicity. Diagnosis in nine of his cases was verified by gross inspection at operation and by biopsy of the pancreas. The study also includes a group of six cases of gastroduodenal ulcer exhibiting clinical and secretory signs of pancreatitis, the existence of which was revealed at operation. A contrast study was made of the pancreatic ferments from the duodenal juice of twenty-nine healthy persons. Biliary tract involvement was present in only one case. Pancreatitis existed as a complication in one out of every five cases of gastroduodenal ulceration. Intestinal parasitism was present in every case, the common finding being that of Ascaris or Tricocephalus. The author believes that the secretion of the parasites may act as an etiologic factor in the causation of this form of pancreatitis. The microscopic studies revealed two types of a pancreatic lesion: the classic edematous pancreatitis and the sclerotic chronic sclerolipomatosis. The author has never encountered a case of hemorrhagic pancreatitis. He does not regard the edematous form as a precursor of hemorrhagic pancreatitis. The author stresses particularly the finding of hyperglycemia in every case. Injection of insulin in these cases was always followed by lowering of hyperglycemia, alleviation of pain and improvement in the general state. Another important laboratory finding was the constant lowering of the pancreatic ferments in the duodenal juice, particularly that of lipase. The author feels on the basis of his experience that insulin treatment will obviate the necessity of performing a cholecystotomy in most of these cases. The insulin is administered in doses of from 15 to 45 units daily until the blood sugar level returns to

normal. He does not consider the objection that these cases may be confused with acute perforating ulcer demanding an immediate operation as valid because the two syndromes present different pictures. The pancreatic crisis described is characterized by agonizing epigastric pain but, unlike a perforating ulcer, it presents only a moderate rigidity of the abdominal wall and a characteristic, almost pathognomonic, sign of distention of the transverse colon. There is a characteristic hyperglycemia and a diminution of the pancreatic ferments in duodenal juice. There is a similarity, according to the author, between the crises caused by pancreatic insufficiency described and the clinical picture of crises due to adrenal insufficiency.

48: 97-192 (Aug.) 1939

*Urethrovesiculodeferential Reflux. J. Perves and H. Duvergey.—p. 97. Perineal Ectopic Testis. A. Puigvert Gorro.—p. 114. Culture of Urines Collected After Massage of Prostate and of Seminal Vesicles in the Detection of Chronic Gonorrhea and as Test of Cure. S. Goligorsky.—p. 118.

Urethrovesiculodeferential Reflux.—Perves and Duvergey designate as urethrovesiculodeferential reflux the passage of a liquid, of urine, sperm or injected substance, from the posterior urethra into the genital system. Normally the orifices of the ejaculatory ducts are physiologically closed and impermeable for injections made into the canal. Serial urethrographies on normal urethras never show the passage of opaque liquid into the genital apparatus of man. Repeated attempts on cadavers either with iodized oil or with colored liquid have been negative; injecting these liquids into the urethra under great pressure never produces reflux into the vesiculodeferential system but rather a rupture of the mucosa with passage into the corpus spongiosum and the venous system of the urethra. As far as the authors know, Brach is the only one who produced injection of the seminal vesicles by way of the urethra in two cadavers. But although it is a demonstrated fact that healthy ejaculatory ducts are impermeable and that urethrovesiculodeferential reflux is never produced in normal urethras, it appears that certain acute or chronic infections of the posterior urethra which are accompanied by a wide opening of the orifices of the ejaculatory ducts can explain this injection of the seminal passages by reflux. After discussing similarities between urethrovesiculodeferential reflux and vesicorenal reflux, the authors present a table in which they list all cases of urethrovesiculodeferential reflux that they collected from the literature. The table lists the name of the author, the injected organ and the cause of the reflux. The table indicates that in five of the twenty cases urethritis and prostatitis was the cause, in nine cases genital bacillosis and in six cases prostatectomy. Further they give detailed descriptions of the four cases which they observed. The first two are related to epididymitis, the bacillary character of which was probable in one and certain in the other. In these two cases the vesicles showed injection. In the other two cases the reflux appeared after prostatectomy; in the first one of these the reflux was active, appearing only in the course of mictional urethrography, otherwise the patient complained of testicular pains on urinating; in the last case the reflux was passive. The passive and active types of reflux correspond to two different pathogenic explanations. In the great majority of cases the reflux is passive; that is, it is a purely mechanical factor due to abnormal permeability of the ejaculatory orifices and it develops in the course of retrograde urethrography under the influence of the pressure of injection. In certain conditions, however, an active reflux exists which necessitates for its production contractions of the bladder.

47: 1117-1124 (July 15) 1939

Vaccinations and the Public. A. Touraine.—p. 1117. *Importance of Spinal Anesthesia in Pathogenic Diagnosis of Megacolon: Its Eventual Therapeutic Utilization. V. Climesco, P. Sarbu and S. Roman.—p. 1118.

Spinal Anesthesia in Megacolon.—Climesco and his associates report the successful employment of spinal anesthesia in the treatment of megacolon. The patient, a girl aged 12 years, was admitted for fistulous coxalgia but a few days after admission developed digestive disorders evidenced by vomiting,

tympanism and prolonged constipation. Clinical examinations coupled with anamnesis of the patient indicated the manifest presence of megacolon of the Hirschsprung type. Spinal anesthesia induced with procaine hydrochloride (0.1 Gm. in an 8 per cent solution) and primarily used to aid plastic intervention by the Hibbs method yielded an unexpected secondary result by normalizing the patient's evacuations for a period of sixteen days. The second administration of the same drug regularized her stools for nearly four months. According to the authors, the value of spinal therapy consists in giving free play to the parasympathetic nerves by paralyzing the sympathetic and thus activating peristalsis of the colon. It has the advantage of simplicity, requires no great surgical skill, forestalls more serious surgery and produces no immediate or delayed sequels.

*Acaprin in Treatment of Chronic Malarial Splenomegalies. I. Radvan.—p. 1143.

Acaprin in Malarial Splenomegalies.—Radvan maintains that fever and hypertrophy of the spleen, the most important symptoms of malaria, are not influenced in the same manner by the specific therapy, for, if the fever is rapidly suppressed, the hypertrophy of the spleen frequently persists. In order to counteract the splenic hypertrophy that fails to yield to the specific treatment, the author employed as an adjuvant acaprin, a quinoline preparation. The satisfactory results he obtained with this method induced him to report his experiences with this treatment. The doses employed by him were usually slightly below 1 mg. per kilogram of body weight, 1 mg. per kilogram being the maximal dose. The substance is administered in the form of an aqueous solution by subcutaneous or intramuscular injection. The rhythm and number of injections are fixed in accordance with the reaction of the patient to the medicament. Generally, from two to five injections are given at intervals of from two to three days. As long as fever exists, it is advisable to give first quinine or other antimalarial medicaments. After apyrexia has been established and the parasitic elements have disappeared from the peripheral blood, the author begins treatment with acaprin, which is without danger if the aforementioned doses are not exceeded. It rapidly reduces the size of the splenic tumor and counteracts the splenic pains. Moreover, there follows improvement in the general condition and in the anemia and an increase in the weight of the patient.

Couve and H. Delhumeau.—p. 836.

"Reactivation" in Serodiagnosis of Tuberculosis.—According to Meyer and Froyez-Røderer, it is well known that the seroreactions for tuberculosis may give negative results in a certain number of cases of established tuberculosis. Most of the patients were persons examined at the beginning of the infection or cachectic persons in a state of anergy, a state in the course of which the cutaneous reaction is likewise negative. But aside from these cases there are others in which, in spite of a favorable general condition, a manifest and progressive tuberculosis is accompanied by a negative seroreaction. The latter nevertheless can become strongly positive when the patients are treated with tuberculin. It is known, for instance, that a small dose of tuberculin which is without effect on

normal guinea pigs or rabbits may give rise to an abundant production of antibodies in tuberculous animals. If in human subjects the conditions are the same, there is a possibility of augmenting the proportion of positive reactions in cases of tuberculosis. This "reactivation" of the seroreaction is effected by the authors by means of the intracutaneous injection of small doses of tuberculin. They employed this method in 100 cases in which the seroreaction was negative, freedom from tuberculosis existing in fifty and osteo-articular or glandular processes of a tuberculous nature being present in fifty. They found that by the injection of small doses of tuberculin it is possible to increase in tuberculous subjects the occurrence of positive seroreactions, the increase being from 87 to 95 per cent in adults and from 70 to 85 per cent in children. In nontuberculous subjects the same procedure is without effect on the subjects with a negative cutaneous reaction, but it provokes a positive seroreaction in more than a third of the persons who have a positive cutaneous reaction. A seroreaction which becomes positive under the influence of tuberculin, although not presenting an absolute indication, can raise suspicion of an active tuberculosis; a reaction that remains negative suggests with considerable probability, particularly in adults, the absence of an active tuberculous process.

Anemia with Bartonella Muris: Aspects and Development, Action of Antianemic Hepatic Factors. M. Lourau, G.-S. de Sacy and A. Arthus.—p. 749.

Glutathione Content of Blood Hemopathies.—Émile-Weil and his associates point out that it has been demonstrated in numerous investigations that glutathione plays an important part in the process of oxidoreduction of the organism. They cite methods by which it is determined in the blood. They made their own investigations with the method of Binet and Weller, which seemed to them the most specific. They studied the glutathione (total, reduced and oxidized) content of the blood of fourteen patients with leukemia and cryptoleukemia, of four with polycythemia, of three with erythroblastosis and one with myeloma. The hemograms of the patients were examined simultaneously and in the majority of them the basal metabolism was likewise determined. They found that in polyglobulism the total glutathione was constantly elevated and seemed to increase with the number of erythrocytes. The amount of oxidized glutathione as well as the glutathionemic quotient, however, varied greatly. The leukemias were likewise characterized by a certain augmentation of the total glutathione, but the augmentation was less pronounced and had no relation to the leukocytosis. The latter, on the other hand, seemed to influence the amount of oxidized glutathione. There was a tendency toward elevation in the myelogenic leukemias, but almost complete disappearance in the lymphatic forms. It was likewise absent in a case of glandular lymphomatosis, whereas, contrary to the true lymphatic leukemias, it was normal or elevated in two cases of splenic lymphomatosis. The erythroblastoses were characterized by the complete absence of the oxidized form. Finally, no relationship could be observed between the glutathione and the basal metabolism on the one hand and the cholesterol content on the other hand.

*Dihydratichysterol and Thallium. A. Buschke and W. Konheim.—p. 702.
Positive Indications in Serologic Paternity Tests. F. Ottensooser.—p. 703.

Dihydratichysterol and Thallium.—After pointing out that the antitetic preparation dihydratichysterol influences the calcium metabolism, Buschke and Konheim review its favorable effect on the cataract of tetany. They further state that cataract as well as rachitic changes of the bones has been known to develop in animals which have been treated for long periods with thallium, and they decided to investigate whether the

inhibiting effects exerted by thallium on the growth process could be counteracted by medication with dihydratichysterol. One group of young rats, weighing between 55 and 65 Gm., was given dihydratichysterol as well as thallium, whereas a control group was given only thallium. It was found that the controls remained much smaller than the animals which in addition had been given dihydratichysterol. At the end of several months the control animals weighed only 85 Gm., whereas the animals which had received the dihydratichysterol weighed 250 Gm. Later the authors made the same experiments on two other series of rats and obtained the same results. The experiments prove that dihydratichysterol is capable of inhibiting the impairment of growth produced by thallium. However, a modification of the hair growth could not be observed. The authors consider it probable that thallium exerts an unfavorable influence also on the parathyroids, which are an important factor in the growth of bones, and that the dihydratichysterol again promotes the function of the parathyroids as in tetany and tetany cataract. To be sure, it is known that osseous growth is influenced also by the hypophysis, thyroid, thymus and sex organs and it has been determined that the function of these organs is impaired by thallium. Additional metabolic and microscopic studies will be necessary to obtain more information about the relations between thallium and dihydratichysterol.

Value of Behavior of Reticuloocytes in Pulmonary Tuberculosis in Children. G. Murano and G. Fiordelisi.—p. 498.
Early Tuberculous Infiltration in Children and Adolescents: Importance of Pathogenesis of Phthisis. E. Filla.—p. 517.

Tuberculous Allergy.—Pellegrini and Carinci followed the behavior of tuberculous allergy in a group of 138 adult patients who were suffering from either pleuropulmonary tuberculosis or nontuberculous diseases. Allergy was determined by means of the intradermal and cutaneous reactions to anatuberculin (a tuberculin preparation), which were carried on simultaneously. The intradermal reaction gave positive results in eighty-one cases, in fifty-two of which the skin reaction also gave positive results. Both tests gave negative results (anergy) in fifty-seven cases in the group, including several in which mild forms of chronic pleuropulmonary tuberculosis were present. The author found that a positive cutaneous reaction appears within the first twelve hours in the course of the test, whereas a positive intradermal reaction appears late (regularly it appears after the first twelve hours and in some cases as late as about forty-eight hours in the course of the test). The tests can be simultaneously made without any inconvenience to the patients or any interference with the results. The cutaneous reaction gives positive results only in cases in which the intradermal reaction is going to be strongly positive. It shows florid forms of pleuropulmonary tuberculosis. The test is of value in association with the intradermal reaction as a criterion for evaluation of the evolution of the disease. The more or less intense positivity of the cutaneous reaction shows the more or less acute evolution of the disease. There are various unknown organic factors which may induce diminution of tuberculous allergy (and even cause anergy) in adults with mild chronic pleuropulmonary tuberculosis. There are also various diseases, especially influenza, malaria, cancer and typhoid, which cause anergy. Rheumatic fever stimulates tuberculous allergy. The latter is of the same degree of intensity in rheumatic fever as it is in pleuropulmonary tuberculosis.

- Vasodilatation of Capillaries Following Compression of Limbs by Rubber Armbrands. R. Ferreira.—p. 763.
*Clinical Problem of Migraine in Children. A. Oliveira Lima.—p. 765.

Migraine in Children.—According to Oliveira Lima, allergy is the main etiologic factor of migraine in children. Heredity and constitutional physical factors, or else pathologic factors, are secondary. The condition is more frequent in girls than in boys and again more frequent in girls of a nervous type than in normal girls. The clinical symptoms are those of the prodromal, aural, attack and after-attack periods. The topography, acuteness and evolution of the disease are varied in the

different cases. The main symptom of the attack is the one-sided headache, which appears at regular or irregular intervals with pain of the oppressive, irradiating or neuralgic types and is accompanied by nausea, vomiting and various sensory disturbances. Intolerance to light is more or less acute in all cases. The after-attack stage gradually establishes itself, after an aggravation of the acute symptoms of the attack. It becomes evident by appearance of physical depression, sleep, disturbances of the secretion and elimination of urine, rhinorrhea and general dull pain. In some cases the development of an abortive or equivalent attack prevents development of typical attacks. Chronic headache may be a late sequel of the disease. The treatments consist of any of the three types (1) preventive, (2) symptomatic and (3) after-attack. There are two forms of preventive treatment: that by which patients are advised not to marry persons who are sensitive to the same allergens, and the actual preventive treatment of the patient, which includes proper diet and avoidance of food and ambient allergens to which the patient is sensitive. Symptomatic treatment varies with the type of headache. The following general measures are indicated: To confine the patient to a dark quiet room and to administer drugs of a vasodilating action during the prodromal and aural stages and, during the attack, administration according to proper indications of drugs of vasoconstrictive action, or else analgesics, sedative drugs and especially ergotamine. Caffeine, calcium and some other drugs can be resorted to, following proper indications. The after-attack treatment is a continuation of the administration of the symptomatic treatment with certain modifications. It consists of the proper diet, rest of the patient and administration of either sedatives or else stimulants according to indications.

Intraleural Chrysotherapy in Insufficient Pneumothorax. B. Cardelle and J. Arias Avellan.—p. 266.

*Endocrine Treatment in Hypertrophy of Prostate. A. Muxó González.—p. 284.

Endocrine Treatment in Prostatic Hypertrophy.—Muxó González administered testosterone propionate to a group of twenty-five patients who had hypertrophy of the prostate of either the first, second or third, degree. The group included (1) patients with moderate or no retention of urine and a normal amount of urea in the blood, (2) patients with acute retention and a high amount of urea in the blood and (3) patients with grave retention and general intoxication. The substance was administered by injections, every other day, in doses of 0.025 Gm. for each injection over a period of three or four weeks. The treatment was repeated after an interval of two months in grave cases at the rate of two injections of the mentioned dose for one week (and in rare grave cases for a month). The author concludes that the testosterone propionate treatment diminishes (or else controls) painful difficult urination and frequent urination. Voluntary micturition becomes free, forceful and abundant. Residual urine, azotemia and hypertrophy diminish (and in some cases disappear). The sexual functions and the general condition of the patient improve. The best results are obtained when the treatment is administered early in the development of hypertrophy. The treatment is also of value for the preparation of patients for a partial endoscopic prostatectomy and as a complementary treatment after prostatectomy. The treatment has its proper indications and it is not a substitute for prostatectomy when the latter is indicated. The author points out the advisability of considering the dose of 0.025 Gm. of the substance as the largest to be administered every other day. The administration of a larger dose or of daily doses in the same amount may cause painful erections.

*Intestinal Intussusception in Infants. A. Lagos García.—p. 521. Chrysotherapy in Rheumatoid Arthritis. V. H. Richieri and J. Davidovsky.—p. 526.

Myxedema of the Heart. C. Lian Faquet.—p. 559.

Intestinal Intussusception in Infants.—Lagos García resorted to surgical treatment in twenty-nine cases of intestinal intussusception in infants, the majority of whom (eighteen) were breast fed. In all cases there was intermittent colic pain

and vomiting. In twenty-seven cases rectal elimination of blood had already occurred when the patients were seen. The tumor could be felt by palpation in twenty cases. The operation was performed as the primary treatment in twenty-seven cases and after failure of the enema of opaque substance with pressure in two cases. The invagination was of the ileocecal type in twenty-one cases and of the ileocolic type in six cases. The twenty-four patients who had the operation before forty-five hours from the beginning of the disease recovered. The five patients who died either had the operation very late or else were extremely young and had acute forms of the disease. In grave cases a given dose of a 10 per cent hypertonic solution of sodium chloride was administered to the patients, intravenously, after the operation. Eventration in one case was the only complication observed in the group. It was successfully treated by a further operation. The author gives the following advice: (1) Resort to the operation early and prevent evisceration, (2) make disinvasion within the abdomen, bringing out of the abdomen only the last portion of the tumor, (3) apply compresses of warm physiologic solution of sodium chloride on the tumor (with the aim of diminishing tension) and (4) perform the operation carefully, rapidly (from fifteen to twenty minutes) and without traction. He concludes that the surgical treatment gives satisfactory results in intestinal intussusception in infants. The danger of the treatment has been exaggerated. The treatment is safe and has the advantage of making amenable to treatment certain forms of ileocolic and ileo-ileal intussusception which cannot be reduced by means of the enema with pressure and also those forms of intussusception which are secondary to local pathologic conditions or to anatomic abnormalities, such as intestinal intussusception complicating enteroid cysts or diverticula.

117: 145-224 (July 21) 1939

*Peculiar Disease of Bronchioles in Nurslings (Interstitial Edema Pneumonia). G. Raspe.—p. 145.

Lymphatic Reaction During Childhood. R. Herget.—p. 152.

Evaporated Milk in Feeding of Nurslings. K. Scheer.—p. 180.

Cholepathies During Childhood: Icterus Caused by Mechanical Occlusion in Girl, Aged 2. W. Goeters.—p. 195.

Hypertension in Diphtheria. Inge Fromm.—p. 198.

Peculiar Disease of Bronchioles in Nurslings.—Raspe describes a peculiar pulmonary disorder which was observed in fifteen nurslings. The majority of the nurslings who contracted this disorder were prematurely born or weak and of subnormal weight. Their ages varied between 7 weeks and 3 months. The maternal anamneses revealed nothing abnormal, at any rate no record of diseases during gestation. However, all the nurslings had had an infection of the upper air passages one or several weeks previous to the development of the pulmonary disorder. The clinical aspects of the pulmonary disorder did not differ greatly from those of pneumonia. The onset was rather sudden, with severe dyspnea, tachypnea, ala nasi respiration, pale cyanotic appearance and slight cough. The infants were usually restless, probably as the result of the great air hunger. The spleen and the liver were nearly always palpable. The temperatures were usually subfebrile and examination of the blood generally disclosed anemia. The physical examination of the lung gave but little information, except that the air content of the lungs was reduced, which was indicated by an increased feeling of resistance during direct palpatory percussion. The respiratory sounds were usually surprisingly soft and hollow. Rales were rarely perceptible. Treatment proved ineffective. Death, with the aspects of suffocation, followed after three to six days. In one nursling the intravenous injection of concentrated solution of dextrose had a favorable effect, but the evaluation of this treatment is impossible since a definite diagnosis can be made only during necropsy. Roentgenoscopy disclosed diffuse, cloudy shadows as seen in atelectasis. On the basis of the clinical aspects, the disorder had to be diagnosed as bronchiolitis, pneumonia or mixed forms of these processes. Only the pathologic anatomic aspects indicate that this disorder is a separate clinical entity. Summarizing these aspects, the author says that the process consists in the excretion of an

exudate which is rich in protein and at first is free from cells, into the finest bronchioles, with simultaneous atelectasis of the majority of alveoli. Following this there is shrinkage and epithelization of the edema and accumulation of lymphocytes and plasma cells in the peribronchiolar tissue and in the alveolar septums, possibly as a reaction to the edema. In this stage most of the nurslings died of suffocation, since the main part of the pulmonary parenchyma could no longer function in the exchange of gases. The author thinks that the disorder is of infectious origin, although the bacteriologic tests produced no uniform results. He also considers it possible that allergization plays a part. This pulmonary process has been observed also in other clinics and it is suggested that it might be identical with the "catarrhe suffocant" (suffocating catarrh) described by French authors.

 *Hyperostosis Frontalis Interna as Symptom of Hypophysial Diabetes. H. Bartelheimer.—p. 1129.

Hyperostosis Frontalis Interna in Hypophysial Diabetes.—Bartelheimer observed several cases of diabetes in which x-ray examination demonstrated the existence of a hyperostosis frontalis interna. The cases presented hypophysial symptoms that indicated hyperfunction of the anterior lobe of the hypophysis and the author shows that it is justified to assume a close relationship between the internal frontal hyperostosis and hypophysial diabetes. Convinced of the hypophysial origin of the frontal hyperostosis, he emphasizes its diagnostic importance in the differentiation between hyperfunctional diabetes, in which the hypophysis and adrenals are involved, and hypofunctional diabetes, in which the pancreas is involved. Further, he directs attention to the constant occurrence of adiposity in cases of frontal hyperostosis and suggests that this indicates deviations in the activity of the basophil cells. Earlier observations had led him to believe that hyperfunction of the basophil cells of the anterior lobe of the hypophysis is responsible for the development of hypophysial diabetes and he thinks that related hypophysial disturbances are responsible for the concurrence of hyperostosis frontalis and hypophysial diabetes. Regarding the treatment of the intense frontal headaches, which are frequently associated with hyperostosis frontalis interna, he says that in one case he was able to counteract them by means of the administration of estrogenic substance (progonyn).

 *Quantitative Determination of Nicotinic Acid and Nicotinic Acid Amide in Urine, Tissues and Blood. K. Ritsert.—p. 934.

Nicotinic Acid Determination in Body Tissues.—Ritsert describes the procedures for and the results of determining the nicotinic acid and the nicotinic acid amide content in the urine, organs and blood of human and animal bodies. His procedures are a modification of the bromcyananiline method and were carried out with the aid of the Pulfrich graduated Zeiss photometer. For the urine test, requiring as little as from 10 to 20 cc. of urine, unselected healthy persons (sex not indicated) were examined. These tests indicated an average nicotinic acid content of from 50 to 300 mg. per hundred cubic centimeters of urine (laboratory tests of the urine of normal rabbits yielded results of between 270 and 650 mg., those of rats from 450 to 650 mg.). To gage the rapidity of excretion, quantities of 100 and 1,000 mg. of nicotinic acid amide were administered, orally and subcutaneously, to rabbits. The major portion of this was eliminated within the first twenty-four hours. Where large doses were administered, only small quantities could be traced: 16 per cent in 100 mg. administration and from 30.6 to 36.9 per cent in 1,000 mg., allowance being made for the normal amount

of nicotinic acid in the urine. It is uncertain whether portions of the amide are destroyed within the body or whether its nitrogen undergoes quivalent transition, thereby ceasing to be colorimetrically ascertainable. The experiment for nicotinic acid content in the organs and tissues was performed on a rabbit according to the method described by the author. The organs examined were the liver, kidney, heart, brain and spinal cord, lung and muscles and flesh. They furnished the following percentage rates per hundred grams of the organ: liver 7.85 mg., kidney 3.8 mg., heart 3.4 mg., brain and spinal cord 1.2 mg., lung 0.9 mg. and musculature (including the flesh) 6.47 mg. The analysis of the blood for nicotinic acid, according to the author's method, which requires as little as 5 cc. of blood, showed the presence of nicotinic acid or its amide in quantities of from 330 to 460 mg. per hundred cubic centimeters compared with 395 mg. in experiments on a castrated ram and from 380 to 460 mg. in rabbits. The author emphasizes throughout the necessity of exactness in the application of the method, stressing especially saponification to preserve the amide of the nicotine acid complex. The disadvantage of using the toxic bromcyananiline is more than outweighed by the simplicity of the method and its suitability for serial examinations.

 *Abuse of Tobacco and Carcinoma of the Lungs. F. H. Müller.—p. 57.

Abuse of Tobacco and Carcinoma of Lungs.—Müller states that considerable increase of primary carcinoma of the lungs has been observed in the recent decades. To explain this increase various causes have been pointed out, such as increased street dust, exhaust gases of motor cars, tarring of the streets, war gases, x-rays, trauma, influenza, tuberculosis and increasing industrialization. There appears to be agreement only as to the exogenic character of the causes. Increased attention has been called of late to the significance of smoking as a cause of carcinoma, and the simultaneous increase of carcinoma of the lungs and consumption of tobacco supports this view. The tar content of tobacco is due mainly to the lignified parts of the leaves such as the veins, and these have been used lately in increased quantities in the manufacture of tobacco. The cancerigenic effect of tobacco tar has been demonstrated on experimental animals. Continued use of tobacco creates in man a disposition to cancer at the place of provocation. The time needed for creating this disposition varies for different persons. The author observed lately a relatively large number of patients with carcinoma of the lungs at the municipal hospital in Cologne. Prompted by this observation he carried out a statistical survey on ninety-six dead patients as to smoking habits and other factors acting on the respiratory tracts, such as soot, dust, smoke, tar, vapors, exhaust gases, coal, metal dust and chemicals. Previous diseases of the respiratory tracts were likewise recorded. Of the ninety-six persons, eighty-six were male and showed the following result as to smoking habits: extreme smokers twenty-five (29.07 per cent), very heavy smokers eighteen (20.93 per cent), heavy smokers thirteen (15.12 per cent), moderate smokers twenty-seven (31.39 per cent) and nonsmokers three (3.49 per cent). Comparison between these and eighty-six healthy persons as to daily consumption of tobacco disclosed that the healthy persons smoked considerably less and that most of them were moderate and medium heavy smokers. On the basis of this statistical survey and bearing in mind the positive results obtained in animal experiments, the author concludes that the great increase of tobacco consumption is primarily responsible for the increase of primary carcinoma of the lungs. The fact that about one third of the subjects surveyed smoked moderately or not at all indicates the presence of other cancerigenic factors besides smoking, such as influenza and industrial working conditions. The great significance of the latter can be inferred from various indications but needs further study. Members of families disposed to cancer and persons with chronic catarrhs of the respiratory tracts should be dissuaded from smoking.
